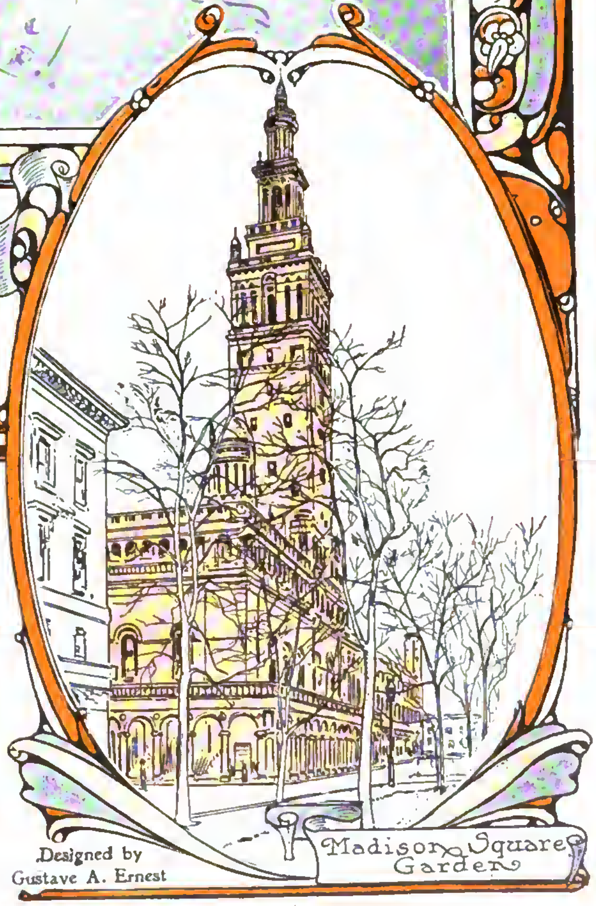
The A.L.A.M. Auto Girl.

A·L·A·M· TENTH NATIONAL SHOW

January 8 to 15, 1910



Designed by Gustave A. Ernest

Madison Square Garden

BIGGER AND BETTER than ever before, the annual show of the Association of Licensed Automobile Manufacturers, which opens in Madison Square Garden on the evening of January 8, will contain the fruits of fifteen years' development and growth on the part of the pioneer automobile manufacturers of America. There will be gathered the product of the oldest and most conservative members of the industry, the criterion by which all others are judged. With a few notable exceptions, the cars exhibited are intended to appeal to the class of buyers who ask the price last, rather than first; to whom elegance of line, detail and appointment is as important as mechanical perfection. The general reduction in automobile prices has, of course, been brought about by the perfection of quantity-producing machinery and the gradually won ability to use it to the fullest advantage. Too complete reliance on the machine, however, is admitted to have an injurious tendency. Again, in the designing of parts to simplify the machine processes through which they must pass, the temptation always arises to sacrifice a point here and there to greater facility of production. Here lies the need for a class of manufacturers to whom price is no object; in whose factories, no matter how clamorous the agent, the micrometer is never fogotten. The consciousness of the inevitable comparison forms the best possible check on any lowering of the standard.

Various are the ways in which the high-priced contingent has assisted—and will assist—the class which appeals to the thinner purse. It was the demand for quality at any cost which induced the steel manufacturers to take up the different kinds of nickel, chrome-nickel and vanadium steels. Once the demand for these was established and the steel plans prepared to produce them, the prices were soon reduced to a point which made their use possible in the lower-priced cars.

In the design of their cars the makers grouped under the Association of Licensed Automobile Manufacturers have always been, as became their position, conservative. Startling features have rarely originated with them. They have persisted in a steady policy of development and refinement, and have usually found themselves on the right side.

The Association of Licensed Automobile Manufacturers has rendered worthy assistance to its members in the work of development. As an organization, it has found a wide field in the reforming of unhealthy conditions in the trade, and in the general process of stabilization. As a head office for many factories, it has done valuable service in the maintenance of laboratories and in evolving standards. To it the industry owes the standard spark-plug, which has almost entirely replaced twenty or more sizes with which accessory makers were formerly compelled to struggle; the standard bolt and nut sizes, the standard rod ends and yokes, and last, but most important of all, the A.L.A.M. horsepower formula. Much has been written both in praise and in disparagement of this formula; yet it seems that if its adoption were to remain the only tangible result of the Association's existence, that existence would not have been quite in vain.

What will be remembered as perhaps the most important event in the whole history of this Licensed Association has been signalized the past year, namely, the favorable decision granted by the courts on the Selden patent. Although there remains a widespread impression that the last word on this subject has not been said, the importance of the decision can hardly be overestimated. Its direct result was practically the doubling of the numerical strength of the Association. Regarded as an association of licensed manufacturers only, this development was of unquestionable value. Regarded in the other light, as an association of leading manufacturers, it was of still more importance.

Many changes had taken place in the industry since the first organization of these manufacturers. Other manufacturers, by dint of honorable effort, had risen to positions as high as those of the pioneers. By reason of its originally limited membership, the Association was unable to accept these as equals and confer upon them its recognition, even if the newcomers had desired this recognition at the price, of course, of paying the Association license fees. The decision confirming the Selden patent not only made it highly advisable that these newly prominent makers should become licensed, but also changed the policy of the Association so that their admittance became possible.

Much has been said about the possibility of overproduction in the automobile industry. At first it was reported—and the report met with some credence—that the object of the enlargement of the Licensed Association was to restrict the output in order to prevent the panic which, according to the same report, was otherwise inevitable. Though now generally discredited, there is food for thought in this possibility.

The automobile industry is at present in an unnatural condition; one which cannot last for but a few years more. At present the market is in the process of being "filled up." Demands for automobiles are constantly arising in new quarters. Three-quarters of the output, perhaps, is being sold to persons who have never owned an automobile before. The time is sure to come when everyone who can profitably use an automobile will have one. Then the only field for the output will be the replacing of machines worn out in service, in addition to a certain amount of natural growth. This is the state of every other great industry in the country which is not of as recent origin, and is the natural state of every industry.

When this time comes there must inevitably be a contraction of the output. That time, it is true, is still several years distant; the market is not yet "filled up," and many new fields of usefulness, particularly in the line of commercial vehicles, have so far received but scant attention. The prudent manufacturers, however, will look ahead, and prudence and foresight could take no better form than the organization of a protective association of those members of the industry whose financial standing and responsibility are undoubted. By action of such an association the natural contraction of the output can be made with the least inconvenience. The change in character may be regretted by some, yet, after all, it is for the best. The principal objects of the old association have been accomplished. The alloy steels, special machinery and special testing devices are now in general use. Moreover, the makers of popular-priced cars have now gained sufficient strength to be able to dispense with outside assistance, and in many cases they themselves are inaugurating new methods.

At this particular moment the feature of the Association of most interest is its conduct of an annual automobile show. The situation in this respect, complicated by the increased membership of the Association, it such that future developments can only be surmised. It seems probthe increased membership of the Association, is such that under the plan in force for the past few years. If the management had desired to make a supreme effort by which its work should be remembered in posterity, the coming show could hardly have been surpassed.

THE LIST OF EXHIBITORS

AMERICAN GASOLINE PLEASURE CARS

ALCO: American Locomotive Co., Providence, R. I.
APPERSON: Apperson Bros. Automobile Co., Kokomo, Ind.
AUTOCAR: Autocar Company, Ardmore, Pa.
BUICK: Buick Motor Co., Flint, Mich.
CADILLAC: Cadillac Motor Car Co., Detroit, Mich.
CHALMERS-DETROIT: Chalmers-Detroit Motor Co., Detroit, Mich.
COLUMBIA: Columbia Motor Car Co., Hartford, Conn.
CORBIN: Corbin Motor Vehicle Corporation, New Britain, Conn.
ELMORE: Elmore Mfg. Co., Clyde, O.
E-M-F: Everitt-Metzger-Flanders Co., Detroit, Mich.
FRANKLIN: H. H. Franklin Mfg. Co., Syracuse, N. Y.
HAYNES: Haynes Automobile Co., Kokomo, Ind.
HUDSON: Hudson Motor Car Co., Detroit, Mich.
KNOX: Knox Automobile Co., Springfield, Mass.
LOCOMOBILE: Locomobile Co. of America, Bridgeport, Conn.
LOZIER: Lozier Motor Co., New York City.
MATHESON: Matheson Motor Car Co., Wilkes-Barre, Pa.
MERCER: Mercer Automobile Co., Trenton, N. J.
OLDSMOBILE: Olds Motor Works, Lansing, Mich.
OVERLAND: Willys-Overland Company, Toledo, O.
PACKARD: Packard Motor Car Co., Detroit, Mich.
PALMER-SINGER: Palmer & Singer Mfg. Co., New York City.
PEERLESS: Peerless Motor Car Co., Cleveland, O.
PIERCE-ARROW: Pierce-Arrow Motor Car Co., Buffalo, N. Y.
POPE-HARTFORD: Pope Mfg. Co., Hartford, Conn.
ROYAL TOURIST: Royal Tourist Car Co., Cleveland, O.
SELDEN: Selden Motor Vehicle Co., Rochester, N. Y.
SIMPLEX: Simplex Automobile Co., New York City.
STEARNS: F. B. Stearns Company, Cleveland, O.
STEVENS-DURYEA: Stevens-Duryea Co., Chicopee Falls, Mass.
STUDEBAKER: Studebaker Automobile Co., South Bend, Ind.
THOMAS: E. R. Thomas Motor Co., Buffalo, N. Y.
WHITE: White Company, Cleveland, O.
WINTON: Winton Motor Carriage Co., Cleveland, O.

COMMERCIAL CARS—GASOLINE AND ELEC.

ALCO: American Locomotive Co., Providence, R. I.
ALDEN-SAMPSON: Alden-Sampson Mfg. Co., Pittsfield, Mass.
AUTOCAR: Autocar Co., Ardmore, Pa.
BAKER: Baker Motor Vehicle Co., Cleveland, O.
FRANKLIN: H. H. Franklin Mfg. Co., Syracuse, N. Y.
GENERAL VEHICLE: General Vehicle Co., Long Island City, N. Y.
HEWITT: Hewitt Motor Co., New York City.
KNOX: Knox Automobile Co., Springfield, Mass.
PACKARD: Packard Motor Car Co., Detroit, Mich.
POPE-HARTFORD: Pope Mfg. Co., Hartford, Conn.
STUDEBAKER: Studebaker Automobile Co., South Bend, Ind.
THOMAS (TAXI): E. R. Thomas Motor Co., Buffalo, N. Y.

ELECTRIC PLEASURE CARS

BABCOCK: Babcock Electric Carriage Co., Buffalo, N. Y.
BAKER: Baker Motor Vehicle Co., Cleveland, O.
BAILEY: S. R. Bailey & Co., Amesbury, Mass.
COLUMBIA: Columbia Motor Car Co., Hartford, Conn.
DETROIT: Anderson Carriage Co., Detroit, Mich.
R & L: Rauch & Lang Carriage Co., Cleveland, O.
STUDEBAKER: Studebaker Automobile Co., South Bend, Ind.
WAVERLEY: Waverley Co., Indianapolis, Ind.
WOODS: Woods Motor Vehicle Co., Chicago, Ill.

MOTOR CYCLES

American Motor Co., Brockton, Mass.
Aurora Automatic Machine Co., Chicago, Ill.
Baker, F. A. & Co., New York City.
Consolidated Mfg. Co., Toledo, O.
Eclipse Machine Co., Elmira, N. Y.
Emblem Mfg. Co., Angola, N. Y.
Excelsior Supply Co., Chicago, Ill.
Greyhound Motor Works, Buffalo, N. Y.
Harley-Davidson Motor Co., Milwaukee, Wis.
Hendee Mfg. Co., Springfield, Mass.
Herring-Curtiss Co., Hammondsport, N. Y.
Marvel Motor Cycle Co., New York City.
Merkel-Light Motor Co., Pottstown, Pa.
Miami Cycle & Mfg. Co., Middletown, O.
New Era Gas Engine Co., Dayton, O.
N. S. U. Motor Co., New York City.
Pierce Cycle Co., Buffalo, N. Y.
Reading-Standard Co., Reading, Pa.
Reliance Motorcycle Co., Owego, N. Y.
Royal Motor Works, Worcester, Mass.
S. D. Mfg. Co., New York City.

Lavigne Mfg. Co., Detroit, Mich.
Lebanon Steel Castings Co., Lebanon, Pa.
Light Mfg. & Foundry Co., Pottstown, Pa.
Link-Belt Co., Philadelphia, Pa.
Livingston Radiator Co., New York City.
McCue Co., Hartford, Conn.
McCord Mfg. Co., Detroit, Mich.
Merchant & Evans, Philadelphia, Pa.
Noonan Tool & Machine Works, Rome, N. Y.
Perfection Spring Co., Cleveland, O.
Prosser, Thos., & Sons, New York City.
Pruden, W. A., Hardware Co.
Randall-Faichney Co., Boston, Mass.
Royal Equipment Co., Bridgeport, Conn.
Smith, A. O., Co., Milwaukee, Wis.
Spicer Universal Joint Mfg. Co., Plainfield, N. J.
Standard Welding Co., Cleveland, O.
Thermoid Rubber Co., Trenton, N. J.
Timken-Detroit Axle Co., Detroit, Mich.
Vanadium Metals Co., New York City.
Warner Gear Co., Muncie, Ind.
Warner Mfg. Co., Detroit, Mich.
Whitney Mfg. Co., Hartford, Conn.

TIRES, RIMS AND SUPPLIES

Ajax-Grieb Rubber Co., Trenton, N. J.
Batavia Rubber Co., Batavia, N. Y.
Burroughs Remountable Rim Co., New York City.
Calmon Asbestos & Rubber Works, New York City.
Consolidated Rubber Co., Akron, O.
Continental Caoutchouc Co., New York City.
Continental Rubber Co., New York City.
Dayton Rubber Mfg. Co., Dayton, O.
Diamond Rubber Co., Akron, O.
Empire Tire Co., Trenton, N. J.
Favary Tire & Cushion Co., New York City.
Federal Rubber Co., Milwaukee, Wis.
Firestone Tire & Rubber Co., Akron, O.
Fisk Rubber Co., Chicopee Falls, Mass.
Fox Metallic Tire Belt Co., New York City.
Goodrich, B. F. Co., Akron, O.
Goodyear Tire & Rubber Co., Akron, O.
G & J Tire Co., Indianapolis, Ind.
Gibney, J. L., & Bro., Philadelphia, Pa.
Hartford Rubber Works, Hartford, Conn.
Hopewell Bros., Cambridge, Mass.
Howard Demountable Rim Co., Trenton, N. J.
Leather Tire Goods Co., Niagara Falls, N. Y.
Merchant & Evans, Philadelphia, Pa.
McGraw Tire & Rubber Co., New York City.
Michelin Tire Co., Milltown, N. J.
Morgan & Wright, Detroit, Mich.
Motz Tire & Rubber Co., Akron, O.
N. J. Car Spring & Rubber Co., Jersey City, N. J.
Pennsylvania Rubber Co., Jeannette, Pa.
Republic Rubber Co., Youngstown, O.
Sager, J. H. Co., Rochester, N. Y.
Seamless Rubber Co., New York City.
Shaler, C. A. Co., Waupun, Wis.
Standard Leather Washer Co., Newark, N. J.
Stein Double Cushion Tire Co., Akron, O.
Swinehart Cushion Tire & Rubber Co., Akron, O.
Voorhees Rubber Mfg. Co., Akron, O.
Woven Steel Hose & Rubber Co., Trenton, N. J.
Zeglen Bullet Proof Cloth Co., Detroit, Mich.

SHOCK ABSORBERS

Flentje, Ernest, Cambridge, Mass.
Gabriel Horn Mfg. Co., Cleveland, O.
Hartford Suspension Co., Jersey City, N. J.
Kilgore Mfg. Co., Boston, Mass.

SUPPLIES

Detroit Motor Car Supply Co., Detroit, Mich.
English & Mersick Co., New Haven, Conn.
Grossman Co., Emil, New York City.
Miller, Chas. E., New York City.
New York Sporting Goods Co., New York City.
Pierson Motor Supply Co., New York City.
Post & Lester Co., Hartford, Conn.
Stevens & Co., New York City.
Victor Auto Supply Co., New York City.

MISCELLANEOUS

Ajax Trunk & Sample Case Co., New York City.
Allers Co., Harry A., New York City.
Asch, B. M., New York City.
Automatic Headlight Co., New York City.
Burn-Boston Battery & Mfg. Co., Boston, Mass.
Chandler Co., Pittsburg, Pa.
Cross, Frank H., New York City.
Dover Stamping & Mfg. Co., Cambridge, Mass.
Excelsior Motor & Mfg. Co., Chicago, Ill.
Gasoline Motor Efficiency Co., Jersey City, N. J.
Grimm-Plaut Construction Co., Pittsburg, Pa.
Hilton Mfg. Co., Boston, Mass.
Hoffnung & Co., New York City.
Kamlee Co., Milwaukee, Wis.
King Optical Co., Julius, New York City.
Mesinger Mfg. Co., H. & T., New York City.

Motor Parts Co., Plainfield, Mass.
Nathan Novelty Mfg. Co., New York City.
Noera Mfg. Co., Waterbury, Conn.
Oliver Mfg. Co., Chicago, Ill.
Perfection Wrench Co., Port Chester, N. Y.
Reilly & Son, Newark, N. J.
Rothstein Mfg. Co., New York City.
Tracy, Joseph, New York City.
Traver Mfg. Co., Philip C., Far Rockaway, N. Y.
Wayne Oil Tank & Pump Co., Ft. Wayne, Ind.
Weed Chain Tire Grip Co., New York City.
Willey Co., C. A., Long Island City, N. Y.
Wright Wrench Mfg. Co., Canton, O.

SHOW COMMITTEE

Coker F. Clarkson
Ass't Gen'l Manager

Chas. Clifton
Pres. A·L·A·M·

Col. Geo. Pope
Chairman Show Committee

Merle L. Downs
Secretary

THE personality of the men comprising the Show Committee of the Association of Licensed Automobile Manufacturers assures excellence of management and careful attention to the mass of details that go to make an exhibition like the Tenth National Automobile Show, which will open for a week's run, at Madison Square Garden, New York City, on Saturday evening, January 8, a successful enterprise.

For four years the A. L. A. M. Show Committee has been headed by Colonel George Pope, under whose experienced eye and guidance each successive exhibition has advanced in character and attractiveness. No one connected with the industry has a wider range of business experience to draw upon, as he has been identified with the making of automobiles since 1897, and prior to that time was a constructor of the automobile's forerunner—the bicycle. He has served as treasurer of the Pope Manufacturing Company for many years, and his military title is one that dates from the Civil War. He was with Colonel Robert Shaw when that gallant soldier fell in the disastrous attack on Fort Wagner, July 18, 1863, and led the veterans of the Fifty-fourth Massachusetts Volunteers in the ceremonies attendant upon the unveiling of the famous Shaw Memorial on Beacon Hill, Boston, about ten years ago.

President Charles Clifton of the A. L. A. M., the second member of the Show Committee, has been prominently identified with the automobile industry since 1898, and has served with credit in many capacities that have identified him with publicly proclaiming the advantages of the motor-driven vehicle. He has always been an active participant in the business affairs of the A. L. A. M. and his election to the presidency of that successful organization was the natural culmination of his energetic work in its behalf. He is treasurer of the Pierce-Arrow Motor Car Company, of Buffalo, N. Y., itself a veteran business enterprise which had its inception in the early days of the bicycle.

Selden, Sr., and Jr.

For six years, Secretary Merle L. Downs, the third member of the committee, has attended to the detail work connected with A. L. A. M. Shows and has done it so well that he has won a recognized position as successful engineer of enterprises of that nature. His knowledge of the automobile business and its requirements is wide and varied, and in the early days of the industry he was prominently identified with the management of racing and touring events that gave wide publicity to the automobile as a self-propelled means of locomotion and helped materially to popularize it.

Although not a member of the Show Committee, Assistant General Manager Coker F. Clarkson, of the A. L. A. M., has much to do with the arrangements. He is the compiler of the A. L. A. M. handbooks, and is secretary of its mechanical branch. This naturally makes him a valuable authority for the committee to consult with, and his wide range of knowledge in engineering and other matters is of great service in the accomplishment of details requiring exactitude and dispatch. Mr. Clarkson is a lawyer by profession.

In the process of standardization of methods, formula, and materials, Mr. Clarkson has been a power to conjure by, and in contests, the fair and conservative attitude always assumed by him has made for him a host of friends, besides commanding the respect of opponents.

LICENSED ASSOCIATION OVERFLOWS GARDEN

EXPANDED by numerous acquisitions from the ranks of the A. M. C. M. A., the A. L. A. M. will make its 1910 début in sufficient force to overflow the Garden and present in dress uniform the finest array of automobiles the world has ever contemplated. The official list of the concerns which will exhibit under the banner of this pioneer association comprises in fact some 56 separate companies, it being the case that the Everitt car will show under the license of the Hewitt Motor Company, the White car using the license of the Waltham Manufacturing Company, and the Willys-Overland Company including the Overland and Marion under the old Pope-Toledo license.

As will be readily appreciated, the licensed association in its present form draws heavily on the ranks of the A. M. C. M. A., taking from the latter such companies as Brush, Stoddard-Dayton, Elmore, E. M. F., Hudson, Jackson, Maxwell, Mitchell, Moline, Moon, Mora, National, Premier, Regal, Reo, besides the companies which were non-members in either association. To what extent these withdrawals will affect the A. M. C. M. A. and its workings in the future is a matter with which we do not now have to deal, but the influence thus exerted on the A. L. A. M. will amount to more than a surface indication.

From what is already known, and considering the needs of the industry, it is believed that the stronger association will have a marked effect on the future, particularly in the direction of quality of the automobiles made, and to a vast extent, by way of inducing stability, all of which should react to the decided advantage of the patrons of the industry. True, prices may be maintained as they should, but the concentrated effort of the members of the association along well directed lines is bound to further the interests of the industry as a whole, and an examination of the automobiles which are to be shown this year, together with a close inspection of the plants in which they were made, renders judgment comprehensive, and prediction potent. If forecasting has any virtue, provided it is in the light of events transpired, it will have in its composition the statement to the future of the automobile industry is well assured.

American Locomotive Company	Alco
Apperson Bros. Auto Co	Apperson

Main Floor of Madison Square Garden, New York City, as Arranged for the Tenth National Automobile Show, January 8-15.

·A·L·A·M· Cars · in · Tabular · Form ·

CONSTRUCTED on the same plane as the table of specifications of the cars exhibited at the A. M. C. M. A. show, which appeared last week, the following table may be regarded as complementary, and the two together give a practically complete summary of the cars at present on the market. It may be stated here, however, that in the issue devoted to the Chicago show another table will be printed which will be a combination of the present two, with the addition of every other make which is built or sold in this country on a commercial scale. That is, the Chicago show table will not be restricted to exhibitors at that show, but will be as complete as it is possible to make such a table, in view of the constant additions to the ranks of the manufacturers.

The preliminary comment on the A. M. C. M. A. table applies as well to the following table of A. L. A. M. cars. For convenience it may be briefly summarized. The prices given are marked by an asterisk when they include a Cape top. Horsepower ratings are in all cases according to the A. L. A. M. formula; two-cycle motors are not rated, but are marked by a dagger in the horsepower column. It seems fair to add in this connection that the two Elmore models, which the maker rates at 36 and 46 horsepower, differ in respect to their motors in a way which the table does not show. The 46-horsepower is a differential-piston design, and although its cylinder dimensions are the same as those of the 36-horsepower, the difference in rating seems to be justified.

Representation of each maker in the table is according to the number of distinct chassis produced, without regard to the different bodies which may be fitted. Practically all touring models will be furnished with a runabout or baby tonneau body if desired, usually at the same price.

Lubrication systems are designated as "pump," "mechanical" and "splash." The first means that the oil is circulated and used repeatedly; the second that the oil is fed to cylinders or bearings by individual pumps, the number of such pumps being indicated whenever possible, and the last that oil is simply poured in the crankcase at given intervals. The location of the change-gear box, which is becoming a detail of considerable importance, is given in the column following the description of the gear and the number of speeds. The word "motor" means that the gear-box forms a single unit with the motor; "frame," that is a separate unit supported from the main frame; and "axle," that it forms a unit with the rear axle. In the next column the word "shaft," indicating that the car is shaft-driven, is followed by a figure "1" or "2," denoting the number of universal joints in the drive-shaft.

The design of the crankshaft is indicated by the items given under the head of motor bearings. The figure indicates the number of crankshaft bearings. In describing the transmission and axle bearings it was frequently found that in many cases different kinds of bearings were used; whenever this occurred the kind which seemed to be in the majority was given the preference.

Frames on the majority of pleasure cars are of pressed steel, which is indicated in the table by the abbreviation "P. steel"; other forms are wood and "armored," or combination wood and steel. Commercial cars frequently use structural steel shapes, either angle or channel.

In the table immediately following, showing the cars classified according to price, a different scheme has been followed. All the variations in body design on any make, whether or not on the same chassis, may be found therein, provided they entail a difference of price. For instance, a runabout model selling at the same price as the touring car is not given, even though it may be on a separate chassis; but a limousine selling at a higher figure is given, although often on the touring car chassis. This condensation was necessary in order to get the size of the tables within reasonable bounds. However, the intending purchaser may always rest assured of being able to obtain a suitable body on any chassis he may fancy.

DIVISION OF THE CARS INTO SIX DIFFERENT PRICE CLASSIFICATIONS

UNDER $1,500.

$600	Maxwell AA	Runabout

· SAID · IN · THE · SELLING ·

ALCO: Arthur N. Jervis, Advertising Manager—For 1910 this company offers a complete line of cars, which, in details of design, materials and workmanship, are unsurpassed. The reasons why a man should buy one of these cars in preference to some other car selling at the same or a different price are as follows:

The double chain drive, also the make-and-break system of ignition, has been discontinued, and all pleasure cars will be made with a shaft drive and a jump spark ignition, the Bosch dual system of high-tension magneto and storage batteries, with one set of spark plugs, being employed. These are the chief changes; they are in conformance with the policy of the company to Americanize the French design of the Alco in order to meet the prevailing demand. The company emphasizes the fact, however, that never is any change made until after it is certain that the quality and all the distinctive character can be maintained.

It is noteworthy in this connection that the shaft drive and floating rear axle construction adopted for all the 1910 cars is no experiment, but an original Alco design that was first introduced on the Alco town car in March, 1907. Since then it has become widely known and been much copied.

Most of the excellent features have been retained, and each one of these is a reason for buying in itself. The special design of rear axle of the full floating type, the French type of engine, Americanized, the anti-fatigue steel used throughout the car regardless of cost, the unusually large and powerful brakes, the deep, square tube radiator, and other features which space prevents the mention of, are all mute but eloquent arguments in favor of the Alco car.

APPERSON: George H. Strout, Sales Manager—To the prospective purchaser of an automobile, the dealer in Apperson cars usually points out that the Apperson Bros. have been constantly building high-grade automobiles for over sixteen years; that no maker in America, and few, if any, in Europe, have had more years of experience in this line of manufacture. Experience is the best teacher, and it has taught Apperson Bros. how to build motor cars that are in no way surpassed in efficiency by any other make of car.

Since every component part of an Apperson car is designed and built throughout in the Apperson factory, the resulting product is a well balanced, homogeneous motor car, built from the best materials the world's markets produce.

All working Apperson parts are made from metals especially selected for the use for which they are to be put, and the parts that bear the greatest strain are treated and tempered in the Apperson factory by a secret process known only to the Apperson Bros.

BUICK: A. G. Southworth, Manager, New York Branch—The aim of the Buick Motor Company is to produce "for the price asked" better cars than any other maker; to give every buyer a square deal, and so make every Buick owner a Buick advertiser. The sale of 18,000 cars in 1909 proves that they have hit the mark.

A Buick car is the best possible automobile investment, because it is backed by a strong company that makes, with few exceptions, everything that enters into the car. They are sold in every civilized country; you can get a part or find a mechanic that knows the car in every hamlet. Their commercial value is proven by the fact that 32,000 are running to-day; few are offered second-hand, and they bring a better percentage of the original price than any other automobile—barring none.

We feature points that have quickly placed Buicks at the head of the motor car procession, viz.: simple, standard construction, overhead valves, self-contained oiling system with circulating pump, and full elliptic rear springs. Silence, ease of operation, economy of upkeep, accessibility of parts and completeness of equipment are combined to a degree seldom found in other cars, while in comfort, design, finish and riding qualities, in which so many cars are deficient, they surpass all other medium-price cars.

Regardless of price, horsepower or number of cylinders, Buick stock cars have won more important stock car races and made more world's stock car records in 1909 than all other cars combined.

We issued through the press a fair challenge. It was never answered. A demonstration in a Buick will show you why.

Hundreds of Buick cars are in daily use that have run over 60,000 miles. Three Buicks purchased three and a half years ago to carry U. S. mail between Torrance and Roswell, N. M., have run 110,000 miles each, covering 110 miles a day on an average of 300 days a year—they are still in active service, with the probability that they will round out five years in Uncle Sam's employment.

Buick customers are satisfied automobile owners. Buick reputation is established; we are not experimenting at your expense. Ask your neighbor—he has one.

CADILLAC: W. C. Leland, General Manager—In a car having a carrying capacity for five passengers or less, the Cadillac "Thirty" is beyond question the most judicious purchase, because it offers greater value than any car made, regardless of price.

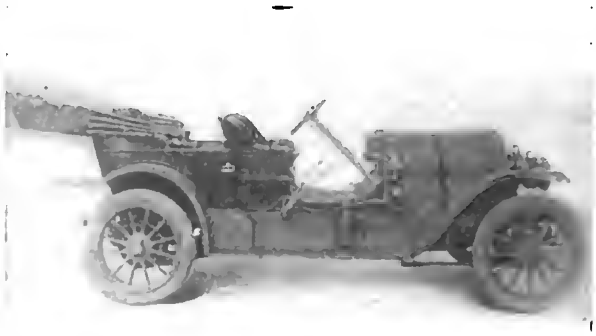
The construction of the Cadillac "Thirty" has for its foundation a half-century's experience in the manufacture of the finest machinery and machine tools. Its materials are selected only after the most careful analysis of the duties they must perform. The workmanship is of the highest type. It is manufactured according to designs, methods, principles and practice which the Cadillac Company has followed for seven years, and which have proven themselves to be as near correct as engineering science has been able to accomplish.

As proof of this statement I may simply point to the all significant fact that there are now approximately thirty thousand cars in use throughout the world. We have yet to hear of a single one which has been discarded because of being worn out or unfit for use, although the first year's output, some two thousand cars, made in 1903, has seen seven years' constant service. I believe that the desideratum of the great majority of automobile buyers is: service, reasonable speed, ample power for reasonable requirements, comfort (both mental and physical), absence of "automobile troubles," dependability and economy. I believe that he gets these to a greater extent in the Cadillac "Thirty" at $1,600 than in any other car at any price.

COLUMBIA: H. W. Nuckols, General Manager—Refinement of detail of design, I believe, first distinguishes the Columbia four-cylinder gasoline car for 1910. With the model first evolved in 1906 there has been opportunity to raise each unit of construction to a very high place and for the year at hand the new car will first interest veteran motorists for a number of little niceties which have been incorporated. Friends have said that it contains more clever features than any car of current building, and I believe it to be true. Also, I think it fair to state that no new car in its first or second year could have been worked out to a state of such high efficiency.

We are building the car as well as Columbias have been built in the past, which means to a fine point of machining accuracy. Further we are provided with a higher quality of raw material than the market has ever previously held. These and what seems to be a fortunate selection of body styles have made for a strong interest in the car. It is most flattering. We are appreciative. It has all along been said that Columbia cars have led in each year but it is patent that the leadership was never so marked as during the present season. Our roadster design merits the praise of being generously copied.

Alco Six-Cylinder Toy Tonneau



Apperson Jack Rabbit Speed Car

Also interest has been exhibited in our new electric, a two-passenger landaulet, for open or closed driving. Changes in electrics are few, which may account for the interest manifested, but further than this, this new landaulet provides, in one vehicle, a carriage for all sorts of weather for shopping, calling, and city and town driving. Our production was at hand fairly early this season, has enjoyed a large sale, and we are making deliveries according to schedule.

CORBIN: L. Goss—Everyone should buy a Corbin car because of the fact that a car is no better than its poorest and weakest part. This matter is governed solely by the standing and backing, which a firm has, since this (if very good) allows the company to make every component part in its own shops. Beyond the ability to do so, the worth of a car lies in the number and character of the component parts actually made under the one factory roof.

The Corbin Motor Vehicle Corporation, of New Britain, Conn., is one of the very few concerns in the automobile industry that designs and manufactures the parts that enter into the makeup of their car. Without an exception, the only parts that this concern is not responsible for are the twenty-two imported annular ball bearings, which are manufactured by Fichtel & Sachs, of Germany. The reason for using these bearings needs no explanation, for it is a well-known fact that these bearings are the best the world affords.

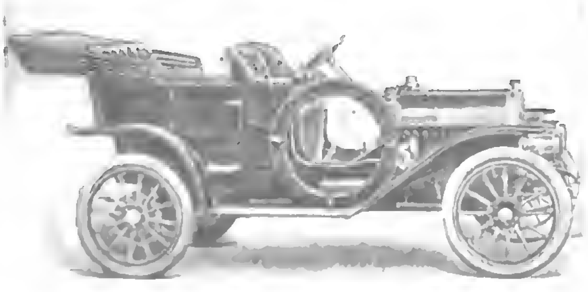
It is not a surprising fact that the Corbin car has reached such a high state of perfection, when you consider the facilities and backing the car has had. The Corbin Motor Vehicle Corporation is one of the leading companies forming the American Hardware Corporation, the other members being P. & F. Corbin Company, Russell & Erwin Manufacturing Company, Corbin Screw Corporation and the Corbin Cabinet Lock Company. Take the combined energies of these concerns and any manufacturing scheme is sure to be successful and will uphold the name "Corbin" the world over. The Corbin car is no exception to this. Starting in a small way, then increasing their production, and still holding to the same general ideas, making changes to the extent of refinements until the Corbin is now considered "The Perfect Car."

ELMORE: Theodore F. McManus, Advertising Department—Speaking of the reasons why a man should buy an Elmore automobile, perhaps the simplest and shortest answer that could be given to this question is contained in the statement that the Elmore represents the only perfect type of the valveless two-cycle engine in existence.

Our devotion to the principles embodied in the Elmore valveless two-cycle engine leads us to believe that if this engine were universally understood, that the public would decline to accept any other type.

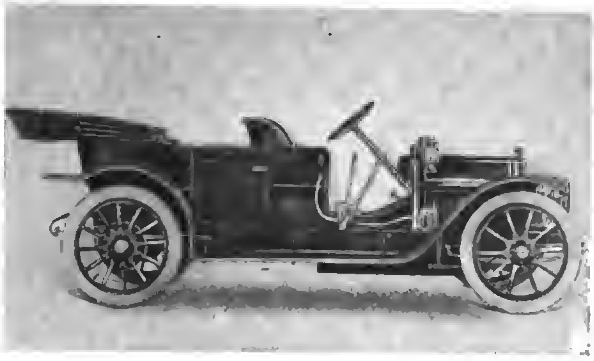
We believe that the Elmore valveless two-cycle engine is the most perfect engine in the world, because it is the simplest engine and because it furnishes that quality of operation to be desired above all others, to wit: an unbroken and continuous flow of power.

The four-cycle engine, in its very highest development, cannot escape the evil consequences of an intermittent application of power, because that evil is inherent in the four-cycle principle itself, and therefore, all four-cycle engines must incorporate it.

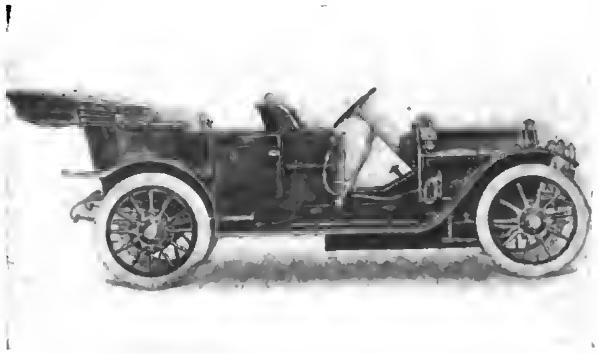


Autocar Type XXII Touring Car

Buick Model 19 Touring Car



Chalmers-Detroit "30" Touring Car



Chalmers-Detroit "40" Touring Car

We believe that the universal acceptance of the principle incorporated in the Elmore valveless two-cycle engine is simply being delayed.

The tremendous impetus that it has acquired in the past five years is being steadily increased.

Manufacturers of six-cylinder cars are filling the public prints with admissions of the inadequacy of the single and four-cylinder four-cycle engines. They justly say that the single-cylinder four-cycle jerks itself alone, and that the four-cylinder four-cycle only differs from the single cylinder, in that it has four times as many jerks.

They announce the change to the six cylinder as a cure for the evil. The error of intermittent power, however, is not in the numbers of cylinders, but in the four-cycle principle itself.

Elmore owners could not be persuaded to exchange the superiorities and advantages of their car for the disadvantages of the four-cycle type, no matter what inducement might be made to them in the matter of price.

As this knowledge spreads—as individual after individual learns that in the Elmore, and in the Elmore only. can he secure the smooth, even, economical operation resultant from the continuous application of power——the abandonment of the four-cycle engine and the adoption of the Elmore valveless two-cycle engine will be multiplied in hundreds and hundreds of cases.

The past eight years have recorded a steadily increasing conversion to the Elmore valveless two-cycle idea, with which it has been manifestly impossihle for even our large and constantly increased equipment to keep pace.

We believe that every man should own an Elmore, because of its valveless two-cycle engine; because it has the simplest motor in the world; because it costs less to keep and maintain than any other car in the world; because it has a motor that never wears out, and runs better after a year's use than when it is new; because this motor starts from the seat oftener than any other; because it has the most economical of all ignition systems, and last, but not least, because the even, rhythmic motion, which results from a continuous application of power, insures a saving on tires, which cannot be paralleled by any car of the four-cycle type.

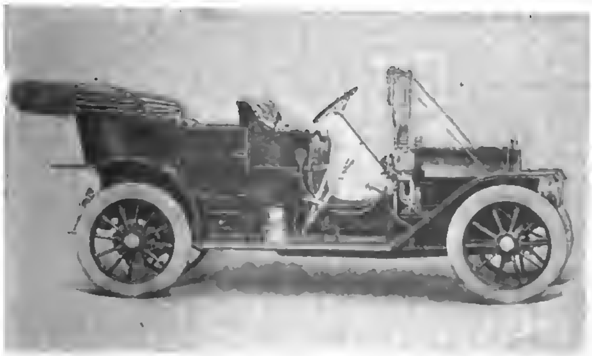
FRANKLIN: Sales Department, H. H. Franklin Mfg. Co.—The purchaser of a Franklin motor car buys riding comfort, road ability, and long service, and he gets an air-cooled motor that is free from the troubles which are common with water-cooled engines. In these two facts center the reasons why a buyer will find it to his advantage to secure a Franklin.

He must first make sure of easy riding, and that is an inevitable accompaniment of light weight, which in the Franklin is effected by consistent construction methods throughout the automobile. Strength and quality are secured without bulk.

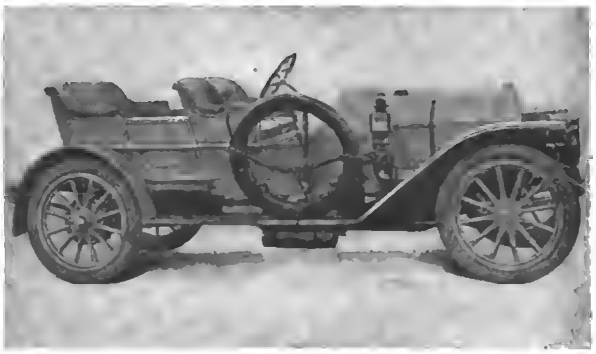
The Franklin is built throughout with a view to absorbing road shocks instead of transmitting them to the passengers. The cushioning effect starts with large tires and large wheels, and is augmented by the use of full-elliptic springs and a laminated-wood chassis frame.

The tires are specially large for the weight which they carry, and this results in greatly prolonging the life of the tires.

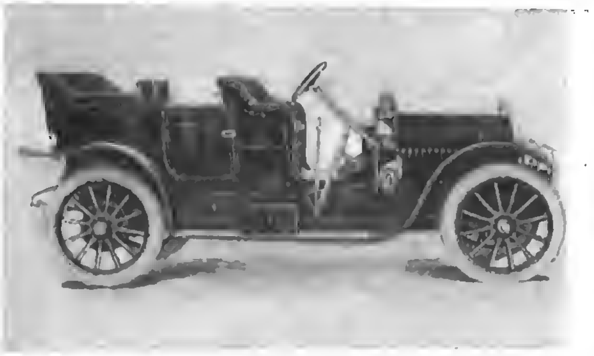
This construction keeps the occupants of the motor car from feeling the jolts of travel, which, in view of the light weight



Cadillac "30" Four-Cylinder Touring



Columbia Model 29 Toy Tonneau



Elmore Model 46 Touring Car

Elmore Model 36 Landaulet

of the Franklin, are much less of themselves than are the jolts made with a heavy, hard-riding, steel-frame automobile.

It is the judgment of many automobilists that three-fourths of the trouble with the average motor is due to the cooling system. In hot weather, the water-cooled engine has a tendency to boil dry and in winter to freeze and burst the water pipes and connections.

With the Franklin air-cooled motor none of this is possible. There is no water to either freeze or boil dry. Like the rest of the automobile, the motor is light and simple. Unnecessary parts are eliminated, and the engine is reduced to the minimum of what is essential for efficient power production.

The buyer of a Franklin secures a comfortable, easy riding, efficient motor car. In body design and appearance, it is all that a high-grade automobile should be. The sheet-aluminum panels of which the body is made are so fashioned as to produce a grace and beauty in harmony with the construction merits of the motor-car.

KNOX: Knox Automobile Company—For the season of 1910 we offer a line of models and types that are unsurpassed. They are designed and equipped to meet the approval of a most exacting public and we have every confidence in their mechanical perfection.

Our aim has been to produce strictly high grade motor cars embodying the most advanced ideas in material and methods of manufacture.

Knox water cooled motors have, ever since their introduction in 1907, proved their superiority over all makes, whether foreign or American. Having this, the most important factor toward the perfect motor car, we have endeavored in every way, regardless of cost of material or expense, to bring every detail beyond a point of criticism, either from a mechanical or selling standpoint. Every part of the construction in Knox models receives months of abuse in actual service before it is considered worthy of adoption.

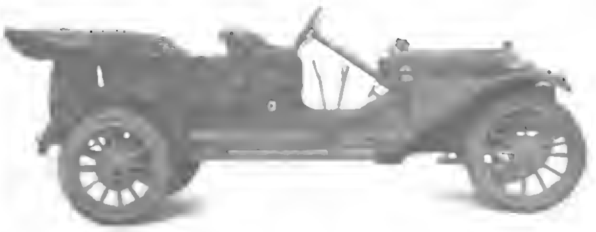
We include three models for 1910: Model "R," four-cylinder, 40-horsepower; Model "M," four-cylinder, 48-horsepower; Model "S," six-cylinder, 60-horsepower.

All have the same general design and construction and all the different types are up-to-date and fully equipped at their selling prices. The quality of material, finish and equipment is of the same high order, whether a Model "R" selling at $3,250 or a Model "S" Limousine at $6,000, quality has been first considered.

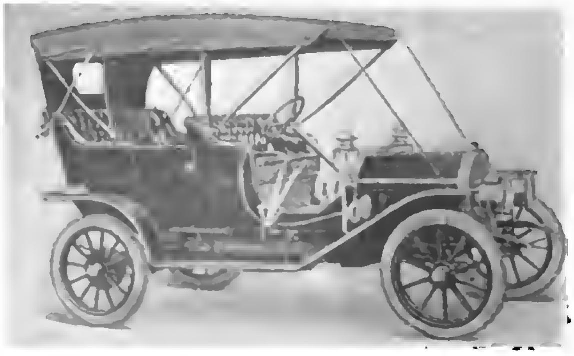
A careful study of Knox construction and a comparison of ability, quietness, accessibility, easy riding, and all that goes to make the up-to-date high grade motor car will easily prove Knox superiority.

LOZIER: C. A. Emise, Publicity Department—The prospective purchaser of an automobile who will study the trend of design in automobiles will be convinced, after an examination of the Lozier, that this car will suit his purposes as well, if not better than any other large high-powered car on the market, and for the following reasons:

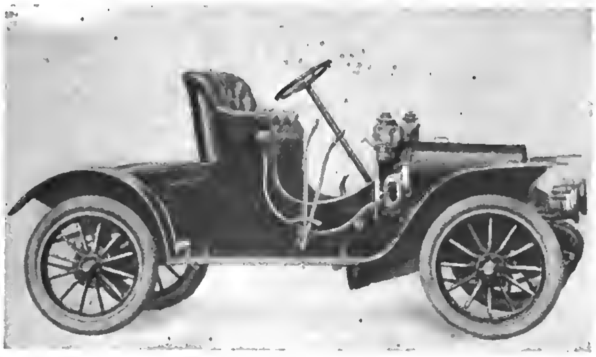
He will find on investigation and by comparison that no desirable improvement as exemplified on other cars is found wanting in the Lozier. A few years ago many features on cars (which features are now recognized as standard) were in dis-



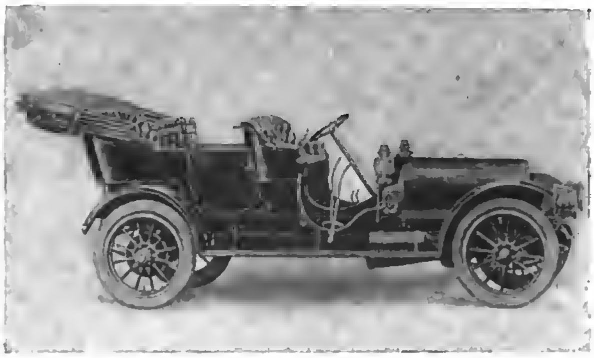
Corbin Four-Cylinder Toy Tonneau



E-M-F "30" Four-Cylinder Touring



Franklin Model G Four-Cylinder Runabout



Franklin Model H Six-Cylinder Touring

pute. For instance, there was discussion as to the relative merits of the progressive or selective type transmission; large or small wheels; long or short wheelbase; ball bearings or plain bearings; low-tension or high-tension ignition; magneto or storage battery ignition; automatic valves vs. mechanically actuated valves. Most of these questions have been definitely settled, and in every instance it will be found that the Lozier has been on the winning side, the features adopted as standard having been incorporated from the first in the Lozier models.

At the present time there are still differences in constructive features of various cars regarding the respective merits of which there is dispute, but with the record of having always been right, it is reasonable to presume that the construction advocated by the Lozier will in the future again prove to be correct. These features refer to ball bearings in the motor, multiple disc clutch, full floating type of rear axle, method of spring suspension, oil systems, narrow turning radius, elimination of numerous universal joints, etc., together with numerous minor points, lack of which might occasion troubles and difficulties which heretofore have been looked upon as necessary.

Among these latter details might be mentioned accessibility of gasoline strainer, accessible position of all oilers and oiling points, accessible adjustments of mechanism, demountable rims, electric lamps, dustless bodies, protection against mud splash and other details of this kind which many designers and purchasers overlook, but which if taken into consideration by the manufacturer assist greatly in the perfect satisfaction which it is possible for a car to afford its owner, and which every one should.

No purchaser of an automobile can possibly find the time to investigate in detail every automobile, and therefore the car and maker enjoying the reputation of never having made a serious mistake in design, construction, or the selection of material should inspire the confidence that impels the selection of that car in preference to the car that has been right some of the time but wrong occasionally, or at best has only adopted improvements a year or two after they have become accepted features of other cars.

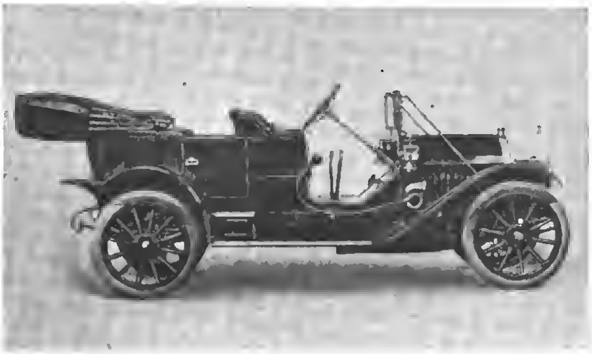
The name "Lozier" is a name that counts for something.

Of course, a car may be perfectly designed and embody practically every desirable constructive feature, but be lacking in strength and durability. There can be no question in the mind of any fair-minded person regarding the durability of the Lozier car after the splendid achievement of this car in endurance contests. The longest races ever run have been 24-hour races. These races in the past three years have been participated in by the most noted cars and drivers of the world. The majority of these 24-hour races have been won by Lozier cars.

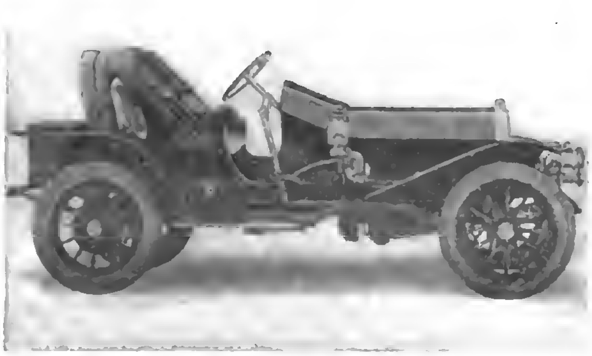
Five times have Lozier cars exceeded former world's record figures, and the Lozier car at the present time holds the world's competition record of 1,196 miles for 24 hours. This is a supreme test of durability, for while a car may perform creditably one, three, five, or even ten hours, it has been demonstrated that any car which can run at full speed for 24 hours must possess endurance and be able to withstand strain and abuse far beyond the requirements of any form of touring work.

OLDSMOBILE: John T. Cutting, Manager of New York Branch—The brief I hold for the Oldsmobiles is a simple one. In its gist, the most pertinent argument that I could put forth, which would convince the man that our cars may best suit his

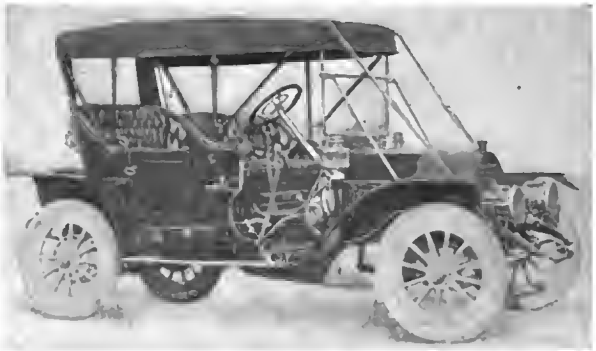
Hudson "20" Four-Cylinder Roadster



Hudson Four-Cylinder Touring Car



Knox Four-Cylinder Sportabout



Knox Model R Close-Coupled

purpose, is that they are "Sui Generis," a Latin expression, which freely translated means, "The only one of its kind," something which has made, and is the occupant of, a class by itself, for no other automobiles have ever made such records for roadability.

A few years ago the statement was made very generally in England, that with the launching of the battleship *Dreadnought* the other navies of the world became obsolete.

With still greater truth it may be said that with the application of big wheels to Oldsmobiles, 36-in. wheels on the "Special" four-cylinder, 40-horsepower model, and 42-in. wheels on the "Limited" six-cylinder, 60-horsepower model, the limitations of all other automobiles using smaller tires became self-evident.

Oldsmobile cars thus removed the last remaining criticism that could be made upon the automobile, by supplying a comfortable and economical need that had hitherto been recognized in all automobiles.

It is still useless to expect to find on other automobiles these features which have given the "Special" and "Limited" Oldsmobile models their high standing among the few great automobiles of the world. The big wheel features are exclusive, and, while other manufacturers may imitate them later on, at present they are original and unique, because used only on the Oldsmobiles.

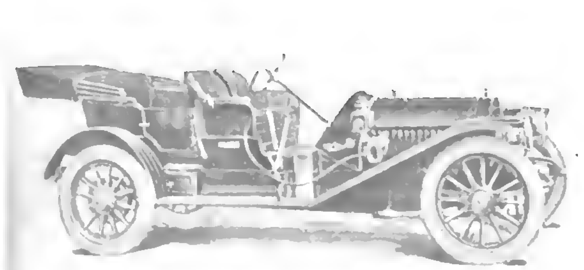
PACKARD: S. D. Waldon, General Manager—There is nothing we might say concerning the desirability of purchasing a Packard car which would be as pertinent and valuable information as our customary suggestion to "Ask the Man Who Owns One."

PALMER-SINGER: Charles A. Singer, Jr., Sales Manager—To a prospective purchaser of Palmer-Singer cars we desire to call particular attention to the following: General design and construction, material used in construction, power and price.

There are no "distinctive features" on Palmer-Singer cars. Every detail and part has been tried out, and after a careful examination of the imported and domestic cars we have taken the best parts of each and embodied them in the Palmer-Singer. Nickel steel is used for the front axle, steering connections, driving shaft and driving axles, also the gears. F. & S. annular ball bearings are used throughout. The radiator is of the honeycomb type—one of the most expensive and efficient on the market. The motors in each model conform to the most approved form of construction and the workmanship and finish cannot be excelled.

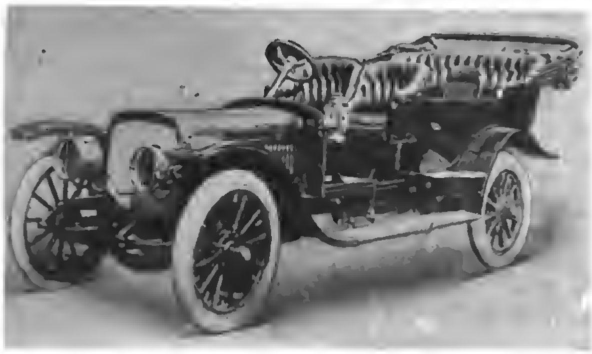
We call particular attention to the power of Palmer-Singer cars. By power we do not mean speed, although we have that too. In touring, power is invaluable and with a four-speed transmission, with which all Palmer-Singer cars are fitted, the combination is ideal. Some owners of three-speed cars do not object to climbing a hill or going over a sandy road on second speed, but the general public is becoming educated and is beginning to appreciate the comfort of a fourth speed, using third for city driving and rough country work.

At the price at which they are sold, Palmer-Singer cars cannot be excelled; in fact, our smallest model at $2,150 compares favorably with any car on the market selling at $3,000 or over, and our six-cylinder model at $3,500 cannot be duplicated for $6,000. In closing, "see for yourself" and do not be misled by clever salesmen.

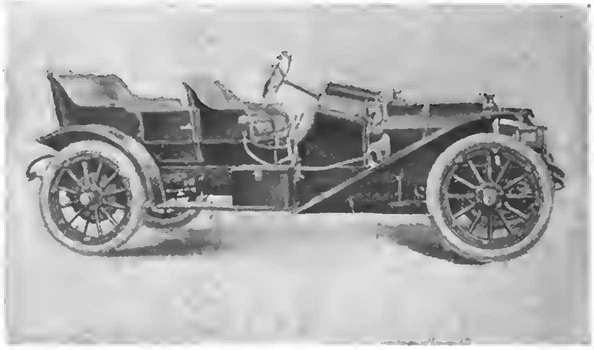


Locomobile Model L Baby Tonneau

Locomobile Model I Limousine



Lozier Six-Cylinder Touring Car



Mercer Model B Toy Tonneau Body

PIERCE-ARROW: R. O. Patten, Sales Department—The unrivaled Pierce-Arrow factory assures the purchaser a product in keeping with all that the best materials and brains can produce. Six-cylinder motors alone are produced, each identically the same excepting dimensions. Careful inspection of raw materials, again, as a finished part, and in the completed vehicle, means that every car is uniform in its perfection, performance, and durability under any and all conditions as proven by a succession of victories in the Glidden and Hower tours.

Able designing and intelligent distribution of weight, combined with the flexibility of six cylinders and the possibilities of lightness, give large tire mileage and long life to the mechanism.

The employment of cast aluminum for body material in every model is a safety factor, combining the elements of lightness and great strength. Individuality and detail are pronounced in the Pierce-Arrow in color and equipment, an art department having been created for that purpose.

Automatic oiling system, with ability to know at all times the available supply, continuous and positive to all bearings, prevents any part from suffering for lack of lubricant distribution.

Dealers' organization in case of any necessity while touring affords prompt and efficient relief at all times.

Three horsepowers and many standard bodies allow a wide range of selection of open and enclosed cars, each combining the most modern and accepted principles of sound engineering design, with ever in mind the comfort of passengers, ease and safety of control, and at the same time, producing a car of beauty as well as unfailing utility.

Nine years of experience with one end in view—the perfect car.

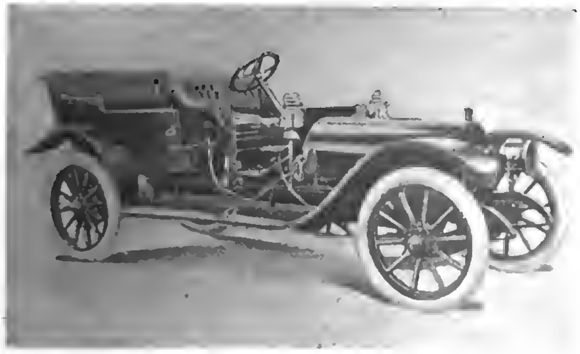
POPE-HARTFORD: H. A. Linehard, Assistant Secretary—The tremendous stimulus to inventive and mechanical genius has developed automobiles which at the price of $2,750 approximate in quality and performance other cars selling at much higher prices. The Pope-Hartford, a conspicuous representative of this class, is a large, handsome car of unusual power, smooth-running qualities and remarkable flexibility. It is reliable, comfortable, a great hill climber, and possesses speed far beyond normal requirements.

Moreover, it is strictly a 1910 car in every respect—not the 1909 car "with refinements." The new lubricating system, giving 750 miles or more with one filling, the remarkably ingenious and effective torque and radius rods, and other distinctive Pope-Hartford features stamp it as a car modern to the highest degree.

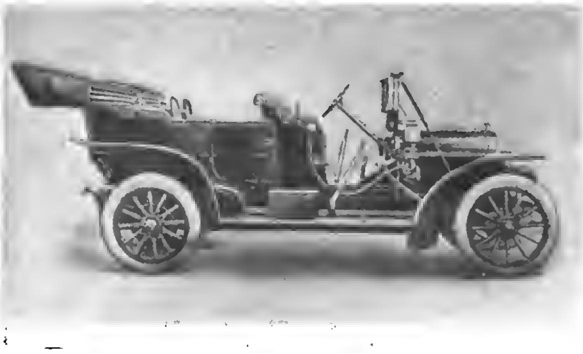
Here is a car of good wheelbase, with a large, handsome body of the latest, straight-line effect, seating comfortably five passengers, and whose engine of 40-horsepower is powerful and flexible enough for every purpose, whether for touring, city use, or racing. A car that can climb stiff grades on the high gear and, as regularly equipped for pleasure driving, is capable of speed over 60 miles an hour on the level.

It long ago proved itself the best hill-climber in its class, and this year a regular stock chassis car made the best time ever made in this country in a long-distance race. It can maintain reliably all day long, up hill and over rough roads with the engine working smoothly and normally, a speed as fast as it is wise or comfortable to travel. In appearance, it is the equal of any car, while in finish and quality of upholstery it could not be excelled.

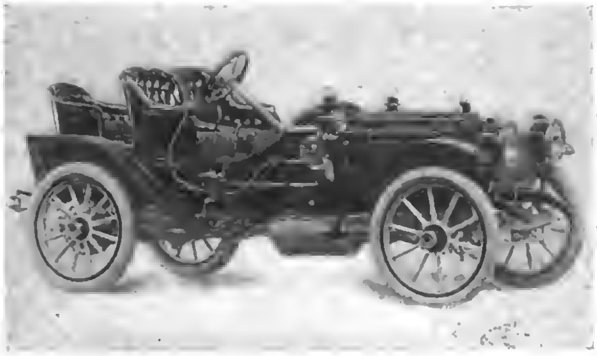
Be it particularly noted that the Pope-Hartford is the selection



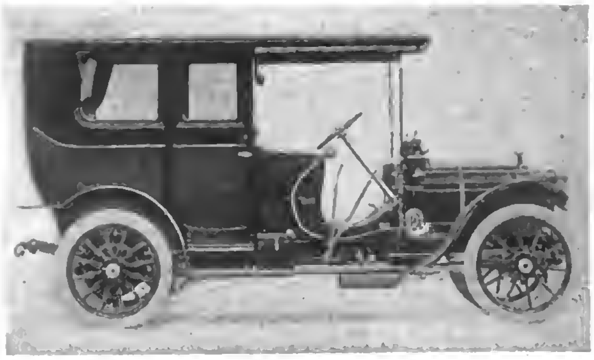
Matheson Model M Six-Cylinder Touring



Matheson Four-Cylinder Seven-Passenger



Packard "18" Four-Cylinder Runabout



Packard "30" With Limousine Body

of owners whose purse has not limited them to the price of $2,750, but whose investigations have led them to know that in all essential requisites the car is the equal of cars costing in some instances nearly twice as much.

ROYAL TOURIST: Hobart M. Adams, Advertising Department—I believe that the purchaser of an automobile should demand that the best of materials as well as the very highest grade of workmanship should be employed on every part of his machine. The other points to be considered are: The motor, the economy of the carbureter, the balance and easy riding qualities of the car, the cost of up-keep, which also includes the possibility of tire trouble. Next come brakes—upon their efficiency depend both life and money.

The day when a motorist confines his driving to city pavements and macadam roads has long ago been relegated to the past. For this reason the present day automobile to be of any great value to its owner must have that durability which only comes from the best material, the highest grade of workmanship and the maximum of motor efficiency.

In the Royal Tourist motor, we believe we have attained the ideal in point of strength and workmanship. After much study we have installed a carburetion system which continued tests have proven the most economical. As to ease of riding, we have demonstrated to the most skeptical that our system of spring suspension, as well as the manner in which the car is balanced, insures to the passengers the maximum of comfort.

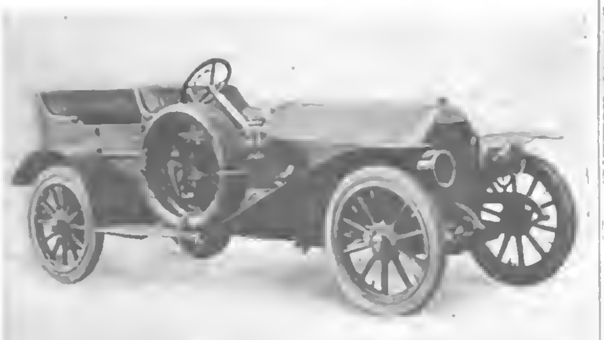
In fact, in the 1910 Royal Tourist we are confident that we have so carefully considered all details that we are ready to make any kind of demonstration that any kind of high-grade car would be called upon to perform. While the Royal is built with the greatest care by the best workmen it is possible to secure, we have also produced a car that the average motorist, with a little study can master—because we have built a car, which, after all, is simply constructed.

SIMPLEX: John G. Dale—A feature which is very important as well as interesting to the prospective buyer, is the fact that our Simplex cars are made in New York City, where any necessary repairs can be promptly made and an abundance of spare parts always on hand. Also, that the material used in the car is not found in any other make of American car, being Krupp chrome nickel steel, which makes it necessary for us to import this material from Germany.

Another strong argument in its favor is the speed and reliability of the car, which has been proven time and time again in road races, 24-hour endurance contests and hill climbs. Although an intending purchaser may not at all be interested in racing, still a favorable impression must have been made by the fact that the Simplex car won in 1909 every speed and endurance contest in which it was entered by this company, showing without any doubt the dependability of the car. In fact to win three consecutive road and 24-hour races is a feat which has never before been accomplished by any make of car, whether foreign or American.

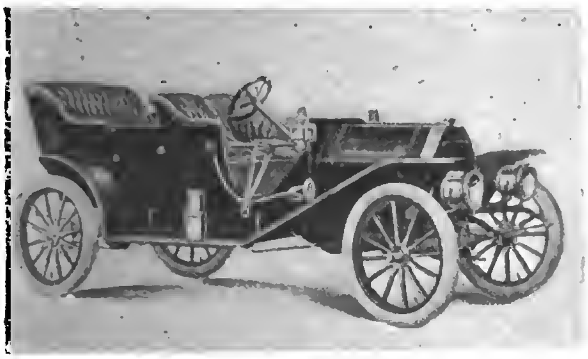
Our final argument would be a reference to all of our customers, which is the best advertisement that any concern may ever expect.

STEARNS: Roy F. York, Vice-President—Long life, easy riding qualities, minimum weight commensurate with power de-

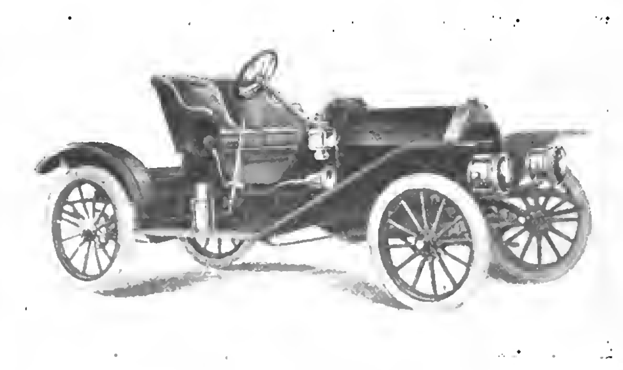


Palmer-Singer Six-Cylinder Touring

Peerless Model 27 Four-Cylinder



Overland Model 42 Touring Car



Overland Model 38 Runabout

veloped and the quality of materials used in the construction of Stearns motor cars are among the most urgent reasons for the purchase of machines of this make.

The long experience of the F. B. Stearns Company—1896 to 1910—coupled with the fact that yearly models are no longer placed on the market, safeguards the purchaser. No Stearns model has ever been withdrawn from the market—a sure guarantee that design and construction are absolutely correct to the minutest detail, and have been from the first.

In buying a Stearns, the purchaser has the satisfaction of knowing that he is securing a car capable of extreme speed when desired—attested by the many records made by Stearns cars in the past ten years. Although the F. B. Stearns Company has never built a racing car in any sense of the word, many records made years ago have withstood all efforts to break them. For over two years our company has refused to enter contests, being followed in this by many leading manufacturers, yet scarcely a month passes that contests are not won by Stearns owners driving their own cars.

In the construction of Stearns cars, the factor of safety has always been of the utmost consideration. It is the belief of our engineers and designers that a motor vehicle should be as safe as possible, regardless of expense of materials or additional cost of workmanship. The Stearns steering gear has often been called "the safest in the world" and not without reason. In driving at high speeds, the life and safety of the occupants of an automobile are absolutely dependent upon the reliability of the steering mechanism, and flaws or weaknesses, either in design or construction of the machine, can well place the lives of those in the car in jeopardy. For this reason the aim has been to render the car as safe at a 65-mile-an-hour speed as at ten.

STEVENS-DURYEA: A. W. Barber—With most of the characteristic features in the design of Stevens-Duryea motor cars motorists are already thoroughly familiar, and it only remains, therefore, to draw special attention to some of the time-tried details of construction for which the Stevens-Duryea Company has an enviable reputation.

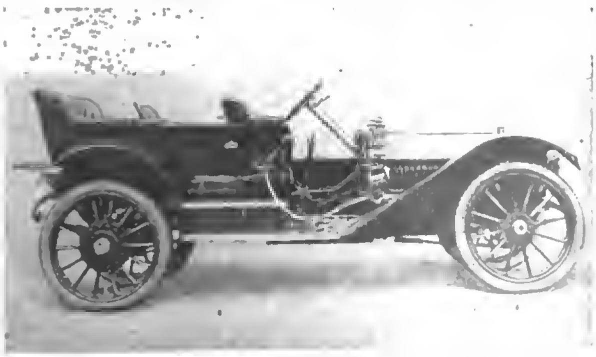
Accessibility not only covering the operating levers, but the component parts of the chassis as well, clearly shows the attention that the engineers have given to the entire car.

The unit power plant, supported on three points, allows for a most compact construction of the motor, clutch and transmission, there being not one section of the unit which cannot be inspected or removed without disturbing body or dash.

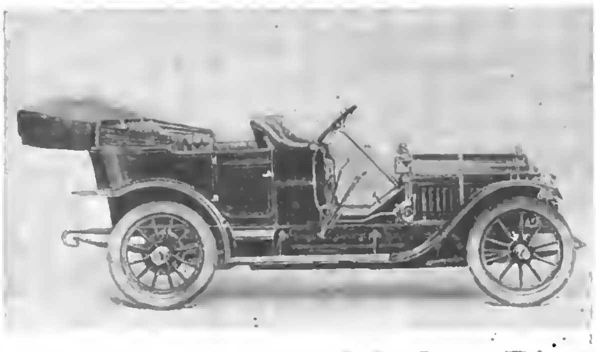
Motor section has an exclusive feature, the removal of one or all pistons without removing the cylinders, crankshaft, or breaking the water or oil connections. By simply removing the lower half of the crankcase the pistons may be withdrawn for inspection or cleaning.

The clutch, which is of multiple disc type running without oil, is of unit construction, directly at the rear of the engine. This clutch has proven eminently successful in all touring cars since 1904, not only because of its simplicity of design and ease of operation, but also due to smoothness with which it applies power of engine to rear construction.

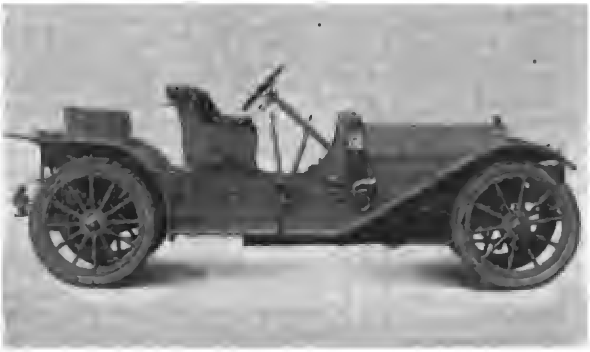
Removal of complete clutch does not necessitate the loosening or displacement of a single nut or bolt of power plant, excepting the aluminum cover and connection with engine and transmission.



Oldsmobile Limited Six-Cylinder



Pope-Hartford Model T Touring



Pierce-Arrow 6-36 Runabout

Pierce-Arrow 6-66 Touring Car

A transmission of the sliding gear type in simpler form could not be incorporated in any motor car. The case is cast without the usual central horizontal division, making it absolutely oil tight, only a cover plate attached by three thumb nuts has to be removed to allow the entire gearing to be inspected, while a complete removal of gears, shafts and bearings may be accomplished by removing oil retaining caps and withdrawing the parts through large opening at top.

Clutch and transmission are directly below the front-seat floor boards. This very accessible location is appreciated as it affords the possibility of a thorough inspection and ease of oiling, so much desired by the tourist.

As a detail in refinement, the keyless construction of the entire drive line is representative of the very highest engineering skill. This emphatic statement is worthy of careful consideration, as this structural feature is exclusive and found only in Stevens-Duryea motor cars. The design used is a series of squares and taper squares at connecting points, making a drive line that runs perfectly true and adding a marked degree of ease in the removal or replacement of a section.

A vibrationless power plant with a wonderful degree of flexibility and power at all speeds, mechanically correct in its design of mounting in chassis frame, has been standardized in all Stevens-Duryea motor cars.

The unit power plant, multiple disc clutch and shaft drive are milestones in motor-car history, and to these features the Stevens-Duryea Company points with enthusiasm, as original with and successfully marketed by them since 1904.

Even a casual glance at the entire line of cars for 1910 boldly brings out the fact that scientific design is synonymous with the name of Stevens-Duryea.

THOMAS: E. R. Thomas, President—Aside from the old reliable Thomas Flyer, which won the New York-Paris race, with which everybody is familiar, we have three other types of cars, known as the Thomas 6-70 Flyer, or Big Six; the new 6-40, Long-Stroke Flyer Model "M," and the Town car.

Each of these models has its strong features, for instance, if I were a man who wanted a large car, I would buy the 6-70 Flyer, because it is the largest, most luxurious, most powerful, easiest riding, most completely equipped automobile constructed.

It is, therefore, in a class by itself—it has no competitor.

On account of the wonderful flexibility of its six-cylinder motor and its excessive power, it is not necessary to "rush" hills or travel fast over bad stretches of road.

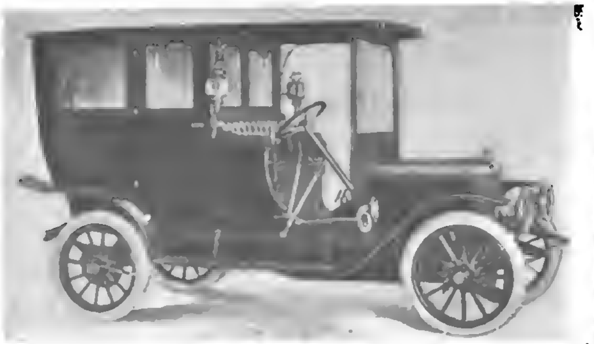
Due to its long wheelbase and splendid spring suspension, this car rides over the worst roads and hills without discomfort.

Then, too, it is possible to travel a greater distance in a day's run, because being a powerful car you avoid the frequent necessity of slowing down to change gears. This car will take almost any hill on high gear.

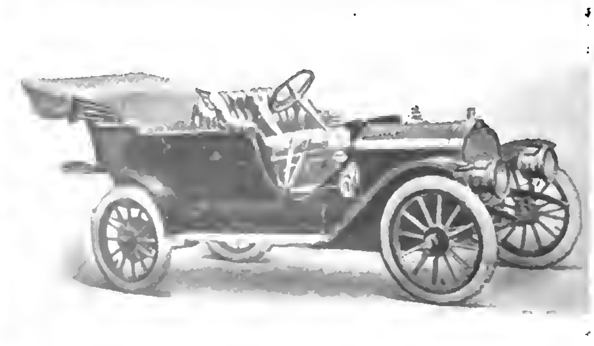
Except for its reserve power, caused by the addition of two cylinders, it is practically the mechanical duplicate of the car that won the 22,000-mile endurance contest around the world with which everybody is familiar.

I think the winning of that event proved that the Thomas Flyer was reliable.

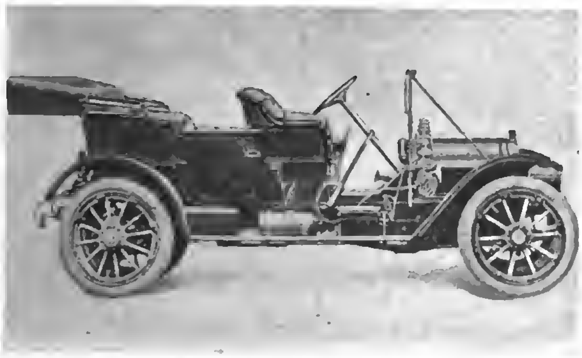
Its price of $6,000 include a complete equipment, including a top, glass front and every accessory that the average owner needs.



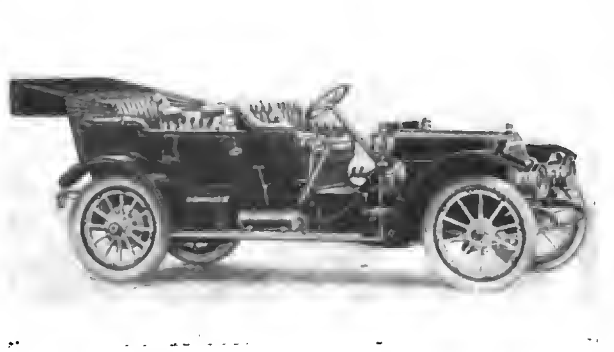
Selden Model 29 Limousine Body



Selden Model 35 Touring Car



Stearns 15-30 Four-Cylinder Touring Car



Stearns 30-60 Four-Cylinder Touring Car

The new 6-40 "Long-Stroke" Flyer is the best buy on the market for the man of moderate means for three reasons.

First, while it is rated at 40, it actually develops 60 on test, so you can see that it has plenty of power for its weight.

Its six-cylinder long-stroke motor has a flexibility which is wonderful. You can run from two to sixty miles an hour on high gear, and that's something which I think no other car can do.

The price of $3,500 includes nearly $500 worth of equipment, consisting of a beautiful silk mohair top, folding glass front, speedometer, shock absorbers, acetylene headlights, oil side and tail lamps, horn, robe rail, tire irons, Prestolite tank, and a complete set of tools, not to mention the tire equipment which is larger than that used on a great many cars of greater weight and higher price.

WHITE: Windsor T. White, President—The design of the White gasoline car is at least one year in advance of any other American machine. At the recent automobile show in London the White was classed with five or six of the leading foreign makes as being of the most advanced design among the cars exhibited. The White is the only American car which has the true "long-stroke" motor and is the only American car wherein the intake and exhaust passages are contained within the engine casting. The "long-stroke" motor is being adopted by the leading foreign builders, as it has been settled beyond all question that a "long-stroke" motor gives increased power, increased efficiency, and far better fuel economy.

There are many advantages of including the intake and exhaust passages within the engine casting. First of all, the design is greatly simplified and this construction gives an unusually neat appearing engine, for the reason that there are no external manifolds.

There is but a single intake pipe leading from the carbureter to the engine, and but a single exhaust pipe leading from the engine. The intake gases are heated while on their way through these passages to the cylinders, with the result that there is no condensation of the charge, and, therefere, every particle of fuel is used efficiently.

Exhaust passages within the engine casting are surrounded by water-jackets, with the result that the exhaust gases are cooled as soon as they issue from the cylinders, and there is, therefore, a considerable reduction in their pressure. This reduction of back pressure is another factor which tends toward unusual economy and efficiency.

Another feature in which the White differs from all other American cars of moderate price and moderate power, is that it has a four-speed transmission with direct drive on the third. The third gear is utilized for running around town and for the average touring conditions, while the fourth speed is used whenever conditions permit of very fast running.

These two purposes cannot be properly combined in a single gear and the attempt to make a third gear answer for both moderate speed and for very high speed is not good engineering and has not proven satisfactory.

The materials used in the White car are the best which money can buy. For many of the materials used we pay just twice what is ordinarily paid for materials entering into cars of moderate size and moderate price.

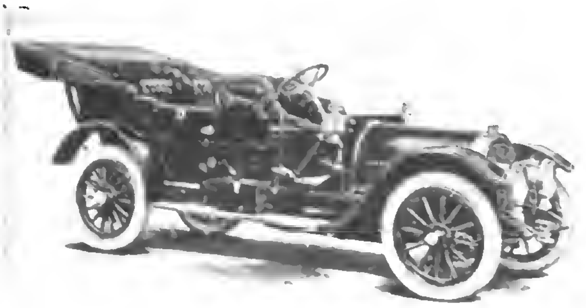
Stevens-Duryea Model XXX Four-Cylinder



Royal Tourist Four-Cylinder Touring

Studebaker-Garford Model G-7 Limousine

WINTON: Charles W. Churchill, Sales Manager—Among the reasons why a prospective purchaser should decide upon the Winton Six rather than any other car are:

It is a six-cylinder car, the type now ranking as highest in motor car construction.

Its motor starts from the seat without cranking, thereby obviating physical labor of an objectionable and sometimes embarrassing kind.

Its cost of up-keep has proved it to be the most economical car to maintain.

Its purchase price more nearly represents actual physical value than does the price of any other high-quality car on the market.

TOO LATE FOR REGULAR ARRANGEMENT

CHALMERS-DETROIT: Carl H. Page, Metropolitan Selling Agent—The 1910 models of the Chalmers-Detroit cars require little, if any, explanation. We have nothing to defend because nothing untried; nothing to argue about because no theories to advance. A year ago perhaps the situation was a little different. Then we were announcing a revolutionary innovation in automobile making—a strictly high-grade, five-passenger car for fifteen hundred dollars. The value we claimed for this car at the price above was enough to insure that the car would be given the most careful scrutiny by the public and the trade. The unusual value offered, taken with certain features of construction new to this country, gave rival manufacturers and dealers an opportunity for adverse criticism—an opportunity which many embraced and held.

A two-bearing crankshaft, cylinders cast *en bloc*, the unit power plant, one-pedal control, ball-bearing construction—all came in for bitter attack. They said we had a theoretical car that could not make good. Now after watching it in use by owners all over the country—after reading the marvelous records for speed and endurance it has set after all kinds of contests for a year—everybody is forced to admit that if it was a theoretical car from the beginning, then the theory must have been right, for no car in use has given more complete satisfaction.

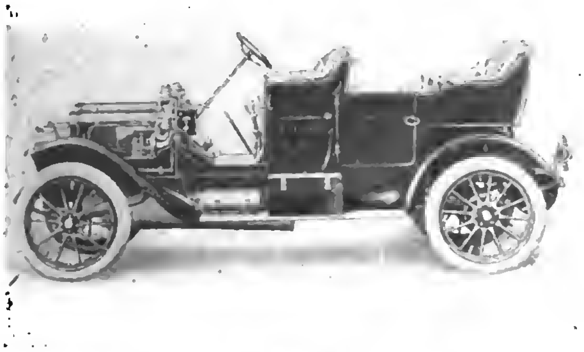
Greatest among the things we or anyone can say about any car we might build is simply that "it is a Chalmers-Detroit." That name means more than any single feature—more than any one part—more than any argument or opinion. It is the sum total of all the good points—it is the stamp of genuineness—a badge of merit and superior excellence.

For 1910, the general policy of the Chalmers-Detroit Motor Company is unchanged. It has been our policy always to give the greatest motor car value for the price asked. We do not want any prospective buyer of an automobile to believe these things merely because we say them—make your own investigations. If you do not know, yourself, ask someone who does. The more a man knows about automobile construction, the easier it is for us to sell him a Chalmers-Detroit car. "The utmost value at the price" is our ambition, and we let Chalmers-Detroit owners say whether we realize it.

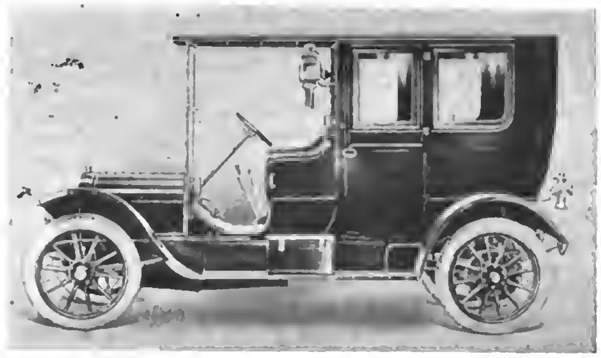
MATHESON: C. W. Matheson, President, Matheson Automobile Company—Almost every Matheson customer has previously owned one or more automobiles of other manufacture. The percentage of Matheson customers having previously

Thomas Flyer Model M Six-Cylinder Touring

Winton Model 48 Six-Cylinder Touring



White Model O-O Steamer Touring Body



White Model G-B Gasoline Limousine

owned other cars was so large, that we undertook to determine, if possible, how many Matheson owners had ever changed to any other car after purchasing a Matheson, with the following results: Out of all the returns received from customers who had bought Matheson cars as far back as 1905, only two had ever changed to any other car; one expressed regret for having made the change and the second changed back to the Matheson again this season after having driven one season with another car. Over 90% of Matheson owners have previously owned other cars. The above facts indicate a degree of reliability in Matheson construction which apparently was not equalled by any other make of cars which our customers had previously owned.

Further statistics gathered from Matheson owners resulted in the following showing: Average mileage per car, 12,840 miles; average repair expense per 12,840 miles, $36.41; average miles per original set of tires, 4,086, and average miles per gallon of gasoline, 11 miles.

The average prospective customer readily understands the meaning of the above records.

Finally we sum up our claims when we publish in our catalogue that the 1910 Matheson Six is guaranteed to be better constructed, swifter, more economical in fuel consumption and tire wear, more comfortable and to have more thoroughly mechanical and approved features of design than any other six-cylinder car on the market, European or American, at any price.

Three thousand dollars buys the Matheson Six and $5,000 buys the Matheson Four, both cars being the most indestructible cars of their respective types on the market according to our claims and guaranty, and according to the freely-given testimony of our hundreds upon hundreds of satisfied customers.

SELDEN: Charles Van Horne, Sales Manager—When George B. Selden built his first automobile and secured from the Government his famous Patent No. 549,160, he offered the world the best the times afforded; it was a practical working automobile, but it was in advance of the age; people were not ready for it; capitalists whom he tried to interest in the business thought him visionary, chimerical, impractical, a dreamer.

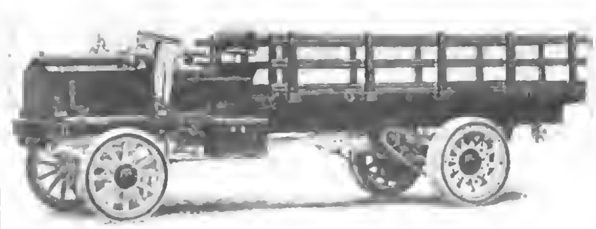
Yet the car built at that time was really the prototype of the car built to-day, just as the first locomotive that pulled a train was the prototype of the modern giant of the rails, but it took time, counted by years, to improve and refine it and standardize its lines.

Of later years the car, most carefully designed by Mr. Selden, with the aid of a corps of expert engineers, after years of further experimentation and study, was as vastly superior to the earlier type as the modern locomotive is superior to Stephenson's primitive engine of 1814. And the analogy is plain and true.

In both cases the earlier creations ran all right, but not as they run to-day. In both cases the essential principles were there, but the improvements and refinements were evolved only with the advance of time. It is perfectly fair to presume that if Elias Howe were now alive and in vigorous health, and at the head of a sewing machine manufactory, he would certainly see that no competing machine could be built better, or embody more good features and improvements than his.

It is in this position that Mr. Selden is placed to-day, when many other good cars are being made by licensees under the

Autocar Model XXI Two-Cylinder Commercial Car



Packard Three-Ton Truck with Platform Body

Selden patent and sold in active but friendly competition, his pride alone in his pet creation, to say nothing of his commercial interests, would make it unnatural and impossible for him to father anything inferior in mechanical features or quality.

This is the spirit which animates his entire factory and selling organization. And it is all so fundamental and so forceful in its logic as to constitute, in my judgment, the best possible reason why the public should have every confidence in and buy the Selden car. There are a great many good reasons why people should buy the Selden car, and this is the reason there are so many good reasons.

COMMERCIAL CARS

ALDEN-SAMPSON: P. H. Breed, Chief Engineer—During the comparatively short time since the Alden Sampson Manufacturing Company, of Pittsfield, Mass., developed and placed one of its four-ton trucks under test in their Motor Transportation Company in Boston, the trucks have excited a tremendous interest among our industries, whose engineers saw at once that here was a truck which embodied ideas and points in design neglected in others, and which seemed to have been designed with the idea that a truck, though doing rough, heavy work, was yet necessarily a machine of fine parts and fine materials, which ought to be protected in their workings to insure economy.

Considering the short time since its development the sales have been most gratifying and the interest shown through inquiries is constantly increasing.

The few points of design and workmanship outlined below will show that the effort to build the best and to greatest advantage of the user is always of universal interest. The engine is of 5-in. bore by 5½-in. stroke, and is governed to run at about 925 r.p.m. It is designed and built by the Alden Sampson Manufacturing Co. especially for truck severity, its main bearings, 2⅛ in. by 4¼ in. and 2⅛ in. by 5¼ in., give an idea of the general design and show that nothing but an engine designed and built especially for truck work will stand.

Other features noted in the engine are thermo-siphon water circulation with 2½-in. pipes, forced oil system through crankshaft, large inspection doors and magneto ignition. A large, lubricated, box-type of universal joint with auxiliary bearing surface for the blocks (patent applied for) transmits the torque of the engine to the transmission case.

This transmission is designed and built especially for the truck, has gears of 4 pitch and about 2-in. face, and the shafts run on Hess-Bright ball bearings, transmitting through hardened 3-pitch bevel gears to the spur gear differential, thence through floating side shafts and roller chains to the rear wheels.

The differential is provided with a simple interlock, which enables its operator to lock both wheels together thus avoiding difficulty if one wheel loses traction or a chain should break.

The chains are enclosed in oiltight, sheet steel cases, which act also as distance members and brake torque supporters, and which insure a continual high efficiency and long life to this most important part of a truck's mechanism.

As the chain case fits down to the small diameter of the hubs, the wheels are built on false hubs, which allow them to be removed without disturbing chain or chain case.

The frame is either reinforced channel section or pressed steel and is hot riveted throughout. Axles are drop forged, of I-section, and carry plain wheel bearings of bronze in steel, the most reliable wheel bearing ever used and of highest efficiency. Every part of the "Sampson" truck is designed and built at the factory of the Alden Sampson Manufacturing Co., and built to jigs and fixtures which guarantee every piece interchangeable.

GENERAL VEHICLE: C. W. Squires, Jr., Sales Department—Of the total number of commercial electric vehicles in use the General Vehicle Company have manufactured over 1,600.

These vehicles embody the adoption of all the valuable features that make for reliability, economy, durability, general excellence in simplicity of design, and highest class workmanship and materials. The rejection of hundreds of ideas that have been found impracticable, or that for any reason would in some detail have reduced the value of the machine to its owner, is best evidenced by the readiness of the General Vehicle Company to give to its customers a guarantee contract limiting the annual cost of upkeep for a period of years within a fixed sum; thus eliminating at once all uncertainty on the part of the owner as to the cost of maintenance of tires, wheels, bearings, steering gear, controller, motor and battery.

There is a growing appreciation of the economic value of the cardinal features of excellence of the electric commercial vehicles of the General Vehicle Company. These salient points are the one motor drive, roller bearings, enlarged battery capacity, and a conservative rating based on a liberal factor of safety throughout all details of the vehicle.

The combination of these features results in a marked reduction in weight, an increased mileage per battery charge, reduced battery maintenance and not less than 50 per cent increase in efficiency over all electrics using two or more motors.

HEWITT: Edward R. Hewitt, President—We have been a long while in the commercial business and have had cars out on the road for four years and a half. In this time a vast amount of experience has been accumulated and the older cars have been carefully observed and their defects noted and corrected in the newer models. We have built cars, from the "light delivery" carrying 1,000 pounds up to the 10-ton truck, in six or seven models.

In all cases we have used the planetary gear with interlocking pedals, and have become assured of the fact that a control in this way is easier to drive and safer in operation in big cities than one controlled by means of a shifting gear box and clutch pedal. This arrangement enables the driver to have both hands on the steering wheel at all times, which is a matter of great importance in heavy cars which often requires considerable effort to control them.

In many cases customers wish to break in their horse drivers or other factory employees to drive the trucks. With this simple pedal control anyone can learn to drive the car in a few minutes, and we have large numbers of cars out which are operated by men who are not skilled automobile drivers. These cars are in most cases working fully as satisfactory as those in the charge of skilled men, especially when the cars are properly inspected on their return to the garage.

We can give our customers cost sheets of maintenance costs of all different types of cars, made out by our customers when the cars have not been in our control. We can refer prospective customers to many of the largest concerns in New York who have been using our cars for a considerable time and have given us repeat orders. This seems to be very good evidence of the value of the cars.

Our motors are constructed with specially large bearings and of very strong materials so that they show a minimum amount of wear, and the whole car is designed so that the maintenance costs will be reduced to the lowest possible point.

We have been pioneers in many of the newer improvements in commercial cars which have been adopted by nearly all our competitors, such as the block tires, the fixed spark with high-tension magneto, the radiator suspended on springs, etc. We can show fully as good gasoline economy with our planetary two-speed box as other manufacturers can show with three and four-speed boxes, thus proving the superiority of our motors. We are doing the same work with the small motor that other manufacturers are doing with the large motor, which means less expense in every way and less wear and tear on the car. Our greatest claim for our cars is the report from every user.

·Distinguishing · Features · Found · In · 1910 · Product ·

By Thos. J. Fay

PRODUCTION in quality will be on a solid basis in all probability, because, in an establishment devoted to production in a large way, the equipment must be on a high plane. For this reason the automobile plants in America have outstripped the foreign producers, the latter devoting themselves, principally, to the limited manufacture of automobiles, using a surfeit of cheap labor, however skilled, in lieu of precision of method, as dictated by automatic machine tools, jigs, fixtures and gauges.

Skilled labor is an absolute essential—and a well conducted establishment counts for much, but, nevertheless, if all facilities afforded depend upon manual labor, even of the highest type, which is not aided or guided by fixtures of precision, then the finished product will be a miscellaneous assortment so far as interchangeability is concerned. This latter much desired quality is absolutely impossible in any plant where men must lay out the work by hand and where they are unaided by appliances which insure accuracy.

This year marks the turning point in the history of American automobiles, and noiseless performance is now regarded as an absolute necessity. The average autoist, while wishing to possess a noiseless performer, merely because the noise is disagreeable, may possibly overlook the basic reasons for noiselessness as a desirable acquisition. Noise is the most certain indicator of lack of harmony as it reflects absence of perfect fit. There is no instrument of precision devised which will so quickly and accurately indicate absence of proper relation as will an ill-contrived arrangement which produces noise, even though it may work.

When noise is present, power is absorbed, and the energy so taken up is dissipated as heat and noise. The noise hurts the feelings of the owner of the car, but it is the heat which does the most damage to the parts. That the noise is a manifestation of a condition which does damage to the parts, is a matter, however, which should not be overlooked. Noise follows vibration, which in turn sets up stresses in the parts vibrated, and in fine, the life of the members may be measured in terms of vibratory value in a testing machine contrived for the purpose. It is now a well-established fact that the vibratory life of ordinary steel is alarmingly short, whereas the same value in the finest alloy products, now to be had, is not high enough to warrant the builder of automobiles to wholly disregard the consequences.

Silent Performance a Sign of Quality—In the successful struggle to avoid noise, the makers of 1910 automobiles have done more by way of introducing quality, than was ever managed in any other way and it has been necessary to concentrate effort on certain units in connection with well-defined parts in order that success might attend the effort. It has always been extremely difficult to make gears so that they will perform noiselessly. Broadly speaking, noise in gears has always been tolerated, and it was the claim of designers that this particular source of noise was not necessarily an indication of a short vibratory life of the parts. They were justified to some extent in this belief, on the ground that the noise was made by the clatter of the teeth in contact.

Unfortunately for such reasoning, the hammer blows, which resulted from this clatter of teeth, were transmitted to the section of metal in the members, and the vibratory ills resulting made it difficult to predict the length by normal life of the parts affected. However, it was fairly well understood that the depreciation was of a serious nature. Two or three years ago, when this phase of automobile building was concluded to be of serious import, it was observed that in painting the chassis, the painter was sometimes inclined to kill noise by allowing the paint to migrate into the bearing surfaces, and as a matter of fact, the painter's carelessness became the maker's method; paint served very well to kill noise, and it served a very good purpose in some of the earlier, indifferent efforts.

This information, together with experience and the improvement of methods, has enabled the high-class builder of automobiles to limit the painter to his legitimate zone of activ-

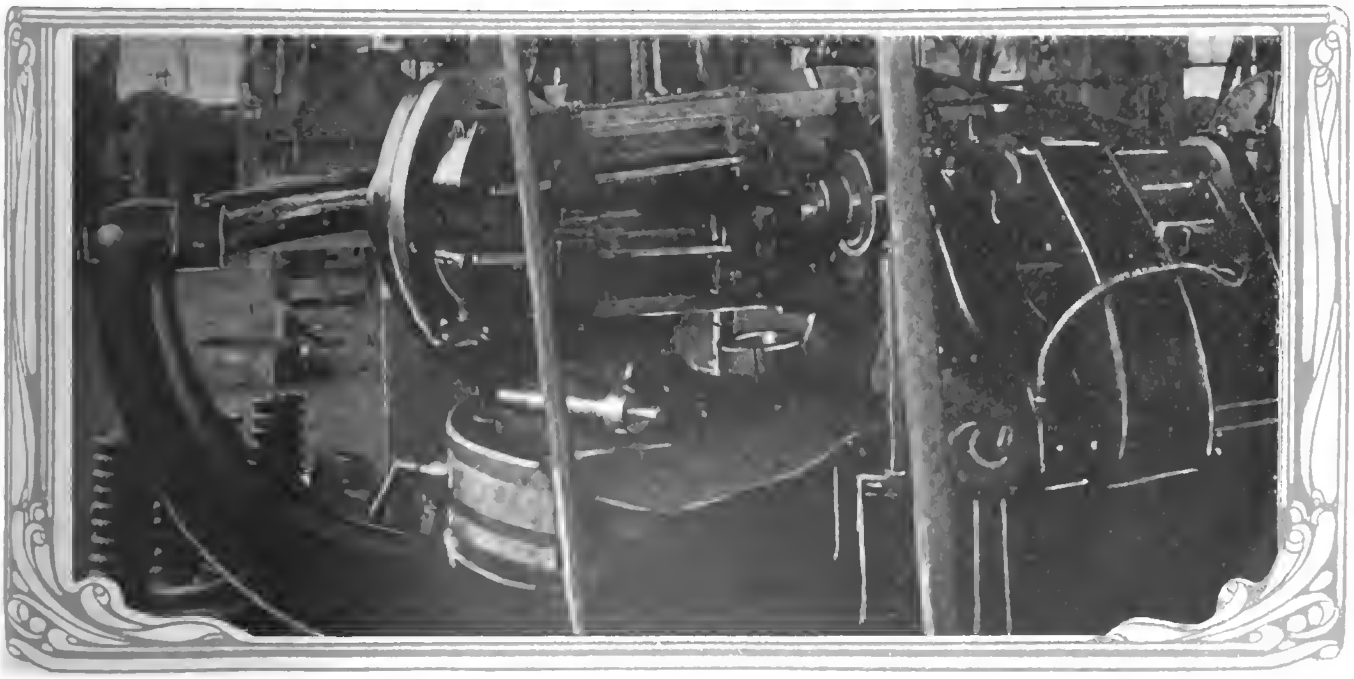


Fig. 1—Gleason planer, used in the Thomas and many other plants to produce noiseless bevel drives

Fig. 2—Fellows shaper, by means of which transmission gears are cut to exact size

ity, by the simple process of making parts so closely to size that noiseless performance is a normal expectation.

BEVEL GEARS

In the production of bevel gears of a 4:1 ratio, which is not uncommon, the gear must have a large number of teeth in order that the pinion will have enough teeth to conform to good practice. It would be the very best practice, were the pinion made with a minimum of 18 teeth, but a minimum of 14 teeth is the absolute limit. With 18 teeth and a 4:1 gear ratio, the gear would have 72 teeth, and would be over 15 inches in diameter were the teeth 5 pitch. In any event, the pitch must be fairly coarse and is frequently 4, whereas it is very rarely finer than 5. These limitations indicate that the gear wheel in the bevel drive must be relatively large in diameter, and designers have learned by experience that it is necessary to fashion them so that they will not deform, either in the machining process, in the planer or while being heat treated.

The first effort towards noiseless gears is made in the engineering office. Here the shape for noiselessness must be devised, and the materials for use selected, in view of the service to be rendered—also the process devised through which the gears are to be put, considering the facilities available in the shop in which they are made.

Bevel gears are in constant mesh, avoid clash and the resultant shock. Consequently they are usually made of die forging, cementing steel, in which it is the aim to limit the carbon content to that which will afford a soft dynamic core as the foundation, thus assuring desired service.

Repeated Annealings During Forging.—In the forging process, which, for the large bevel gear, may require three operations, it is the practice to anneal between operations, partly to save the dies, and finally, to prevent deformation in the after machining and treating processes. To be sure, however, that the gears will not hold internal strains, they are reannealed after sand blasting. This latter process quickly removes the oxided surfaces, and renders the final annealing process more effective. Pickling, which was the former preferred method of removing oxide, has been supplanted by the sand blast in this work, not only because the sand blast is quicker and less expensive, but also on account of the aid it gives the inspector, who, with a little experience, is enabled to locate at a glance blemishes in the metal if they are present.

After the sand blast and the inspection, the forgings are machined to exact size and then copper plated. The copper plating is of considerable depth, it having the facility of shielding the metal, excepting, where the copper is cut away, during the tooth-planing effort, so that in the cementing process only the surfaces which are necessarily to be hard are carbonized.

It has evidently been the experience of the makers who resort to this copper-plating process that gears are more likely to warp if they are carbonized on all surfaces, as is the case in the absence of copper plating. After cementing, considering the copper-plated gears, it has been found that they warp but slightly, and as to strength it would seem to be quite in accordance with the requirements. In this instance, the armor, which is entirely over the toothed surfaces, performs a dual operation, *i. e.*, rendering the surfaces glass hard, and so preventing abrasion and adding strength to the teeth to the extent they adhere to the body with greater tenacity than would be true in the absence of the hardening process.

Matching Up Done Afterwards—In some of the earlier efforts to attain noiselessness, the Packard Company, for illustration, introduced a measuring machine, and by a process of matching up, was enabled to pair off from 55 to 60 per cent. of all the gears made as coming within the standard represented as noiseless. The balance of the gears, while they were thoroughly good in every way, excepting as to this one difficulty, were discarded on the ground that noise was objectionable from too many points of view to be tolerated in Packard automobiles.

The companies which passed beyond the point where noisy gears will be tolerated in their product have introduced the finest types of gear shapers and planers, one of which is shown in Fig. 1. This is a Gleason planer, the photograph having been taken at the Thomas plant in Buffalo. In many of the practices the teeth are gashed in milling machines, or by a hobbing process before they are put in the Gleason planer, or the "builder and shaper." This latter machine is much used in many plants, and the idea of gashing is to "rough out" the excesses of metal in order that the precise tooth-forming machines may do their work with greater speed and unquestioned accuracy, and without damaging the tools, which are relatively delicate and rather high priced.

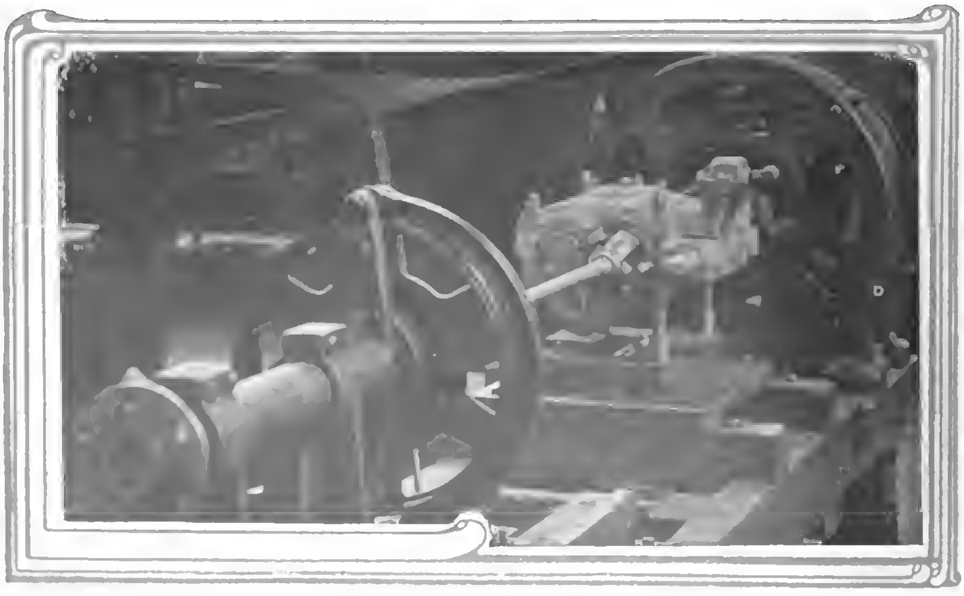

Fig. 3—Pierce-Arrow testing machine, used to load transmission gears to try them out

SQUARE CUT GEARS ARE ACCURATELY MADE

Fig. 2 shows a Fellows shaper working on sliding gears after they are machined to size, and before they are forwarded to heat treating and hardening process. This shaper represents a principle much in vogue—one capable of shaping the teeth to approximately the right theoretical contour. By a strictly shaping method, involving the process of cutting away progressively a little metal at a time, over the faces of the teeth, each tooth in succession being operated upon so that the final cut for the finished surface is the same over every tooth. In this process the shapes conform to theory very nearly.

After the teeth are cut, the gears are set up in a special machine devised for milling the wedge-like contour on the clashing ends; this work was formerly done by hand, but it is now universal practice in America to employ automatic contour milling machines because they reduce cost enormously, besides increasing quality perceptibly, since each tooth is in precise accord with the other—and also the amount of bearing surface of the meshing mates on the pitch line is increased considerably.

Fig. 3 shows how the Pierce-Arrow gear sets are tried out in a testing machine after the whole is assembled. Here the purpose is to first adjust the relations of the matting gears to noiselessness, thereafter ascertained through actual loading, if the system as a whole is strong and to determine the mechanical efficiency, thus proving that there are no undue losses, pinched bearings, or cramped parts, and sweet running qualities are normal expectations without undue care.

This testing equipment shows very clearly in the illustration, and in one way or another tests are made involving the same principle in the better class of plants, to prove out qualities of transmission gears and live rear axles.

Probably one of the distinct advances of recent times in automobile work lies in the fact that testing equipment is afforded, by means of which gears, shafts, and relating members are tested to the absolute limit of the work that will have to be done in practice, with the expectation that they will show competence. This competence, besides involving the use of excellent grades of materials, takes into account special methods of heat treatment and facilities such as Figs. 4 and 5 depict.

These precise methods are the result of accumulated knowledge, due to the effort of many advanced investigators, and in the absence of system it would be utterly impossible to maintain production and quality on the sufficiently high plane desired. This same system, to which all men must become slaves, if they partake of the method, emanates from a supreme and knowing head, ramifies in beaten paths, and is best appreciated when the product of the effort rolls silently away.

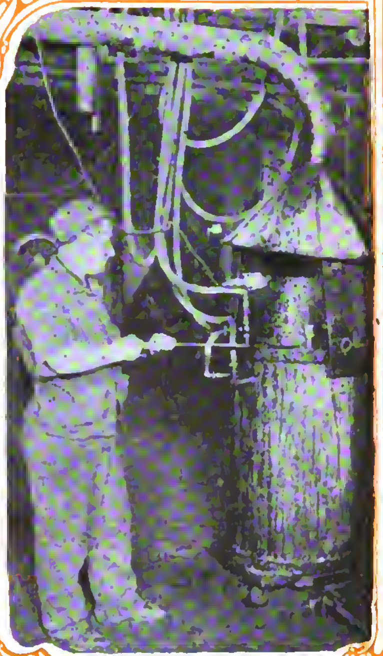

Fig. 5—In the Woods plant, showing one unit of the quenching equipment in which air is used to refrigerate and agitate

Fig. 6 represents a group of brains, brawn and equipment, laid out in a "schematic" sort of a way, with the expectation of accentuating the point to be made. In this group:

(A) Represents the executive head of the establishment, taken at the plant of the Warner Gear Company.

(B) Is the intercommunication system utilizing a central station telephone system.

(C) Represents the executive, stenographic and clerical forces, taken from actual life, at the Rambler plant, Kenosha.

(D) Is emblematical of the engineering office, showing a battery of designers in action at Warner gear plant under the direction of the chief engineer.

(E) Is a testing machine in the laboratory ascertaining the ability of steel to withstand alternate shock components. This view coming from the Woods Motor Vehicle Company, Chicago.

(F) Shows a large press in drop-forging work at the Rambler plant, Kenosha.

(G) Presents a roughing process in the manufacture of crankshafts as used in Excelsior motors.

(H) Shows grinding work in the establishment of the Woods Motor Vehicle Company, Chicago.

(I) Shows a hydraulic press as used in the Pierce-Arrow plant at Buffalo, in the production of high-grade wheels.

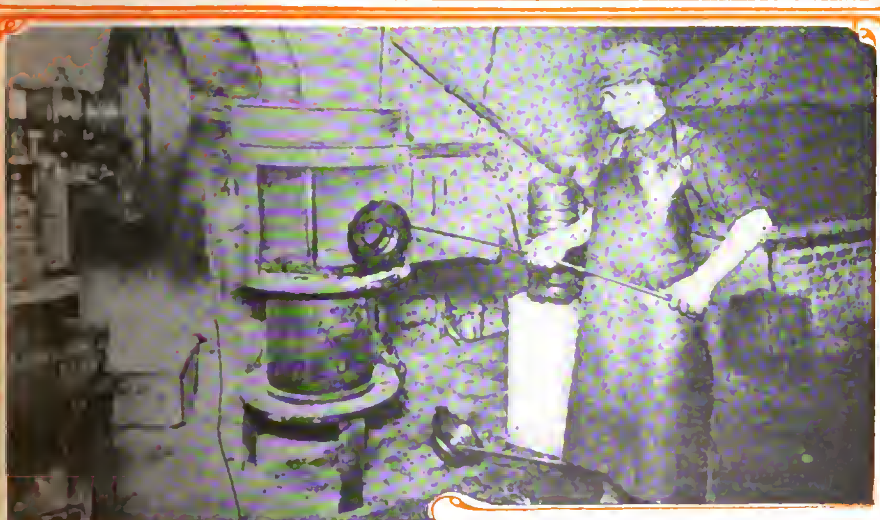

Fig. 4—A corner in the heat-treating department of the Woods plant, showing electric salt baths in the heating process

(J) Shows a disc fan, as manufactured in the McCord plant at Detroit, and, as will be observed, all blades, including the flanging portion, come from a single piece of sheet steel.

(K) Shows the woodwork complete of a wheel as used in a Pierce-Arrow car.

(L) Is a view of the assembling room at the Chalmers-Detroit plant.

(M) Depicts a testing machine with a transmission gear in place, the photograph of which was taken at the Thomas plant in Buffalo.

(N) Shows a special machine with a revolving platen, mounting a number of chucks around the periphery, and the work feeding down from a hopper, thus establishing a continuity of the operation, since the workman feeds the empty chucks during the tooling operations, and as one chuck is invariably in line with the tool, the work goes on uninterrupted.

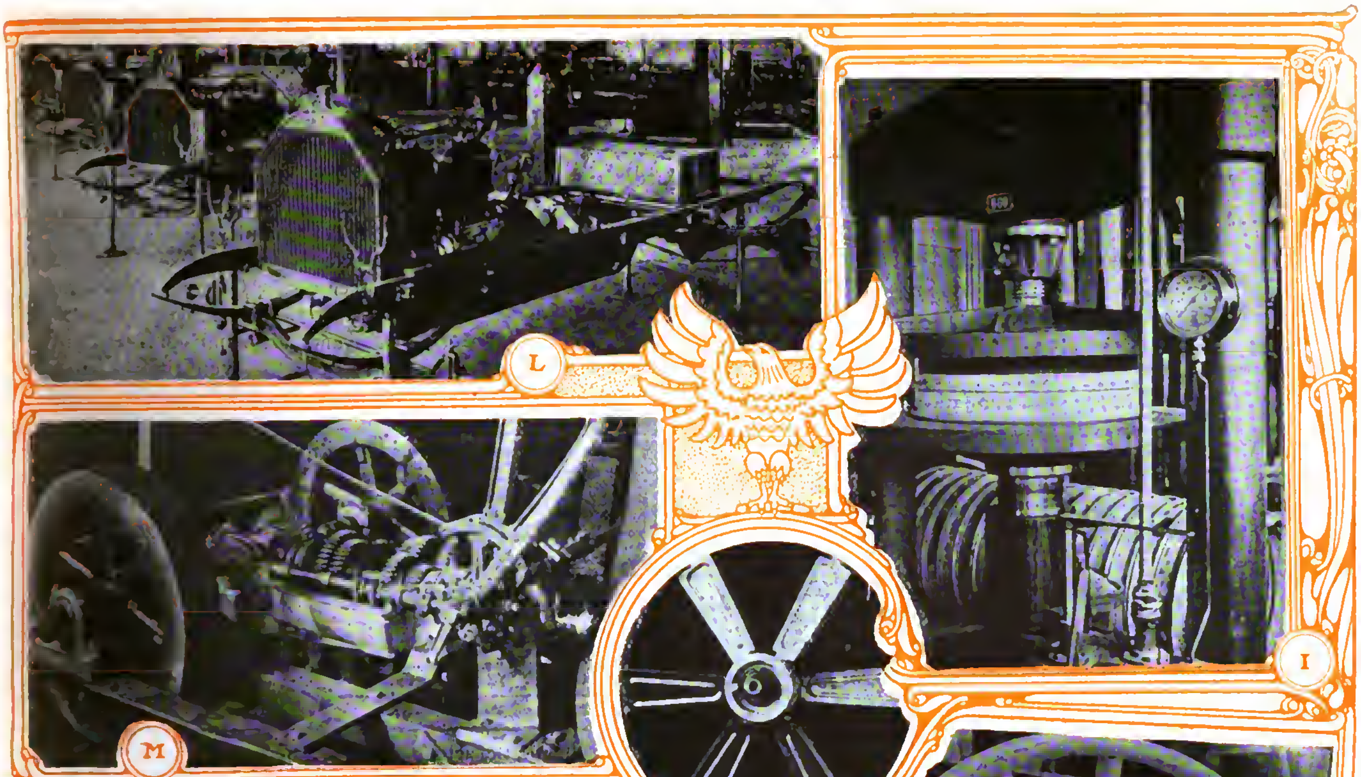
Fig. 5—A series of views clustered to autom

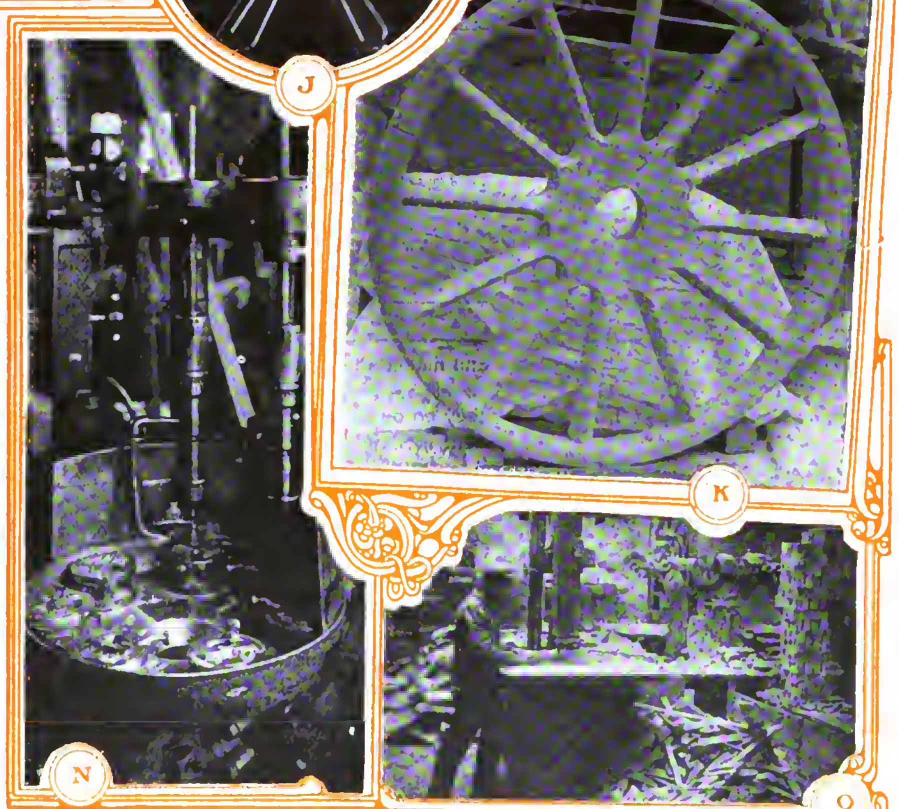
(O and P) Presents details in the process of making the woodwork of wheels, which was taken from foreign practice.

PRODUCTION

The grouping of the illustrations, as shown in Fig. 6, was made with the idea of indicating that there must be a definite connection between the executive head of the business office and the various production departments, in order that the manufactured product shall be representative of, and express the will of, the board of directors. From the executive head rapid methods of intercommunications are necessary, and in the larger plants in which system is regarded as of vital importance communication is direct:

(A) To the chief engineer, who directs the forces in the designing office, and in some cases directly to the production department. In other plants communication is back to the source of all authority. In the Cadillac plant, at Detroit, for illustration, no move of any importance is made excepting as voiced by the president of the company, after a conference is held in which all the principal departments have representation. In other plants, for example, Chalmers-Detroit, drawings are sent out from the designing department directly to the production department through H. E. Coffin, chief engineer. In the Regal plant this question of system is handled in quite a novel way, in that the general manager is in direct communication with every department at all times. In this plant a chief engineer ranks as chief of the designing staff, under the direction of the general manager, and, while he has charge of designing in all its phases, he is, nevertheless, limited to just these functions, and drawings are moved out only in accordance with instructions which emanate from the general manager's office. As an exception, certain routine matters are handled automatically. The system in the Regal plant works extremely well, and, in proceeding, everything is done on a basis of 100 cars, representing a lot going through at one time. Every operation necessary to the completion of 100 cars is made in unison, and, if there is a laggard anywhere, he is smoked out, for the simple reason that the lockstep is broken. At 10 o'clock every morning the executive head is in full possession of information relative to weak spots only. Things which progress on time do not have to be investigated.





Illustrate system in the production of
obiles

(B) In the process of production in the several shops, as a general rule, this important matter is under the head of some one man. The production superintendent, if such he may be called, generally takes instructions directly from the president or general manager, but in some plants the production head takes instructions directly from the chief engineer. At all events, there are very few, if any, automobile establishments which are run without the services of a production manager, whose duties are administrative, and to whom the superintendents or foremen of departments go to for instructions.

(C) In some plants the production manager has charge of the storeroom and warehouses, so that the foremen look to him also for materials with which to carry on the work. As a general rule, however, the materials come in through the action of a purchasing agent, who is in direct communication with the president or general manager. In such instances the storeroom has its own foreman, who works under the direction of a purchasing agent. The foremen in the shop, while they take their instructions through the production representative, go directly to the storeroom for materials, and, in the accounting system, a check is run against the production through the purchasing agent, he being in contact direct with the head storekeeper, and the president of the company, who has reports from the production manager, on the one hand, is able to compare them with reports bearing on the materials being utilized. This constitutes an excellent checking system.

(D) The heads of departments ranking as superintendents or foremen (depending upon the extent of establishments), while taking instructions, in some shops, through the production manager, sometimes receive their instructions directly from the chief engineer. The production head, in such cases, becomes, as it were, a clerk, merely recording from day to day the work done, just as the timekeeper keeps track of the time put in by the men.

(E) Inspectors usually work independently of the heads of departments, and report in some cases to the chief engineer, whereas in other plants reports of this character are forwarded directly to the president or general manager. At all events it is the desire to maintain a certain independence of action of the inspecting force no matter how it is directed, to assure results.

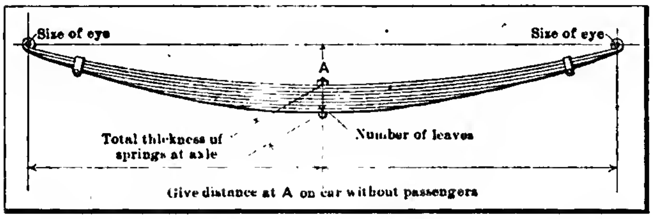


Fig. 6—Half elliptic spring, indicating data required by maker

It is now a fairly well established fact that quantity production on a quality basis is only possible under an operation inspection system. Interchangeability of parts, a factor present in all well-made automobiles, depends upon the accuracy of finishing of each individual piece, and not upon the mere fact that a unit as a motor or a transmission gear will run when it is made. This interchangeability depends entirely upon the inspection of operations, and in plants such as the Pierce-Arrow, for illustration, operation inspections require the services of from twenty-eight to thirty men and a room possibly 50x100 feet in area. All the work, as the operations are completed, must go into this room, be checked with the drawings, have records made, and go out again with

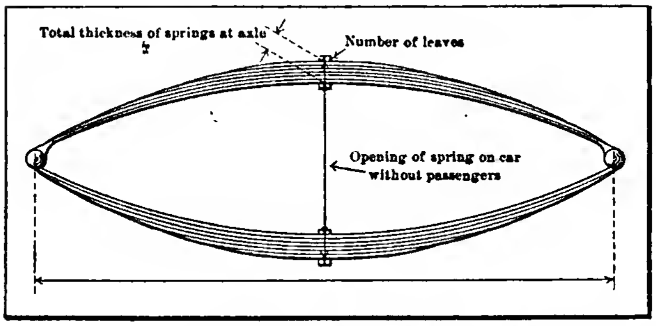

Fig. 7—Full elliptic spring, with forged eyes and maker's indications

such rapidity that successive operations, as they go on in the shop, will not be interrupted for a single moment. Should the inspectors fall behind in their work, the machine tools in the shop will be affected, and the cost of production will go up enormously, to say nothing of delays in delivery.

Besides parts inspection, involving the checking of the goods on every operation, the unit inspection and test is carried on in the several plants, utilizing special equipment and methods, but, as shown in Fig. 3, it is the idea to load the units to some predetermined excess beyond the normal rating, adjust the relating parts to a silent and free-running condition, and thereafter for-

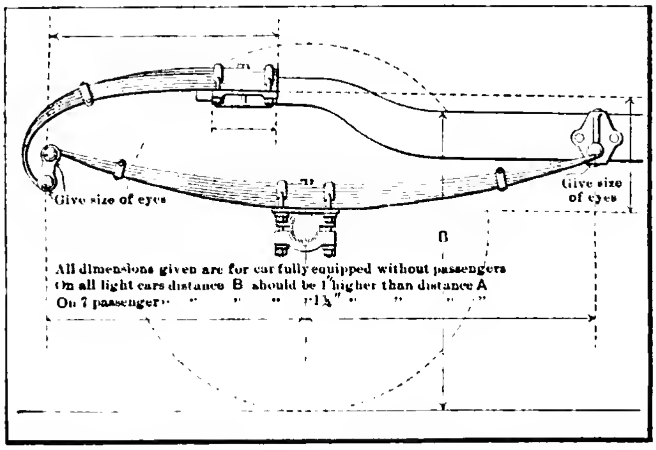

Fig. 8—¾ elliptic scroll spring, showing methods of fastening and H-swivel for flexibility

ward the assembled units to the final assembling department, where, after final assembling, further tests are made before the abuse or road test is taken up. These and many other carefully conducted details in the manufacturing process are reasons why automobiles, as they are to be seen at the Garden, are capable of sustaining under all the conditions of American roads, also why, after running for several years, under normal conditions of depreciation, they are in first-class shape, even though the care afforded them falls far below a desired level.

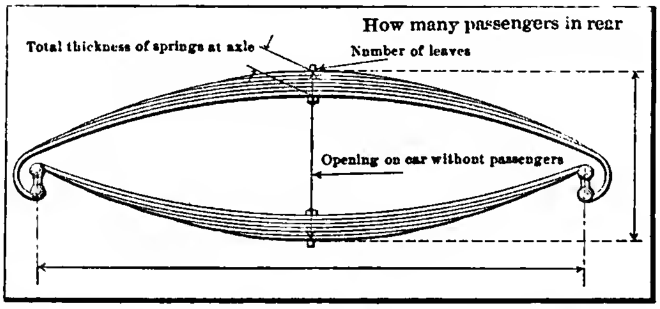

Fig. 9—Full elliptic scroll spring as used on rear suspensions to afford easy riding qualities, taking care of fore and aft oscillations

HIGH AVERAGE OF QUALITY IN PRODUCT

Just what is to be regarded as the particular advance of the year, when reference is made to the quality of the cars exhibited, is a matter which will have to be left to the patrons of this industry. Be it known, however, that an automobile, like a locomotive, is a kinetic machine, in that the stresses and strains partake of diagonal characteristics, whereas, in static work, there are no diagonal efforts, and gravity rules. Before automobile designing reached its present state of perfection it was suspected that the life of material would be shortened under kinetic conditions and that a crankshaft, for illustration, would disintegrate as surely as it revolved in its bearings after a certain time. The only question was, "how long will a crankshaft last?" Automo-

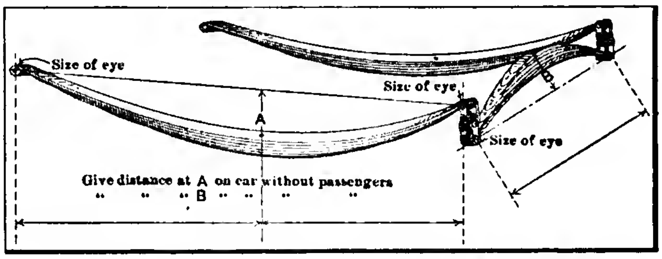

Fig. 10—Example of platform type of spring, showing cross member at rear; may be in front

bile engineers, after having devised divers forms of kinetic testing machines, reached many conclusions which now augment the life of automobiles in which these conclusions are reached.

In a kinetic sense, then, with two phases to consider, the makers of automobiles sought for highly kinetic material, and used the same to satisfy one of these phases. They went further when they designed for flexibility, a matter of the proper utilization of springs on one hand and the suitably placing of universal joints on the other. Equally important is the principle of the three-point suspension, which makes it impossible to transfer a torsional effort from one member to another.

THE SPRING SITUATION CLEARED UP

In the earlier efforts, many of which were copied from foreign cars which were designed to run on Roman roads, half elliptic springs were used, they being rather short, with narrow and relatively thick plates. When these cars were tried out under American conditions the vertical bounce was at a disagreeably high frequency in response to severe road conditions. This reflected but a short pendulum action and a certain inherent inability on the part of the springs.

American designers naturally have had more experience with spring work under severe road conditions, and as soon as they decided to depart from foreign practice they entered upon the half-way which leads to success, and the automobiles which may now be seen have this success embodied in them.

Considering the springs in a general way in the cars of the present year, it will be found that half-elliptic types, when they are used, are pretty generally confined to the constant load conditions such as obtained at the front end, inasmuch as the motor and accessories represent probably 90 per cent. of the actual load carried on the front springs. This is particularly true this year, since the old idea of a "front overhang" has been eliminated, meaning that the radiator is either on the center line of the front axle or back of it. The radiator does not extend to the front of the front axle.

When half-elliptic springs are used at the rear—this being perfectly feasible without fostering trouble—the plates are wide, relatively thin, and there are so many of them that the energy which has to be dissipated, represented in foot-pounds, is within the allowable limits. Consider now that it is well understood that the amount of steel required in the springs is at least one pound of material for five foot-pounds of energy dissipated. Fig. 6 represents the half-elliptical spring idea, and in all the spring illustrations as here afforded it is deemed a good idea to show how the spring-maker is informed as to the requirements, in order that he may do his work with certainty, conditions and the class of material covered by the specifications considered. These illustrations were taken from drawings which were placed at the disposal of the author by the Perfection Spring Company of Cleveland, Ohio.

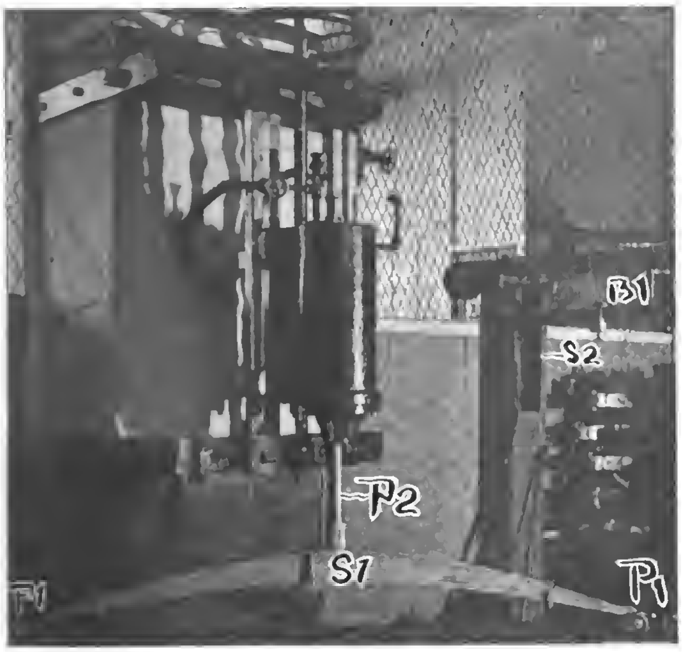

Fig. 11—Spring-testing machine, showing the spring before pressure is applied, and platform scales for registering

Some designers prefer to interject additional flexibility to the spring suspension without having to use long spring plates. These resort to the use of full elliptic type of springs, as shown in Fig. 7. It has never been shown that the total weight of material used in the springs would be twice as much, merely because the full elliptic type is substituted for the half-elliptic form, and, as before stated, it seems to be necessary to use about a certain amount of spring material almost irrespective of the form. The license which designers take in utilizing full elliptic type of springs is justified, and if they prefer to use this same type at the front end as well as at the rear, it has its further justification as a matter of style.

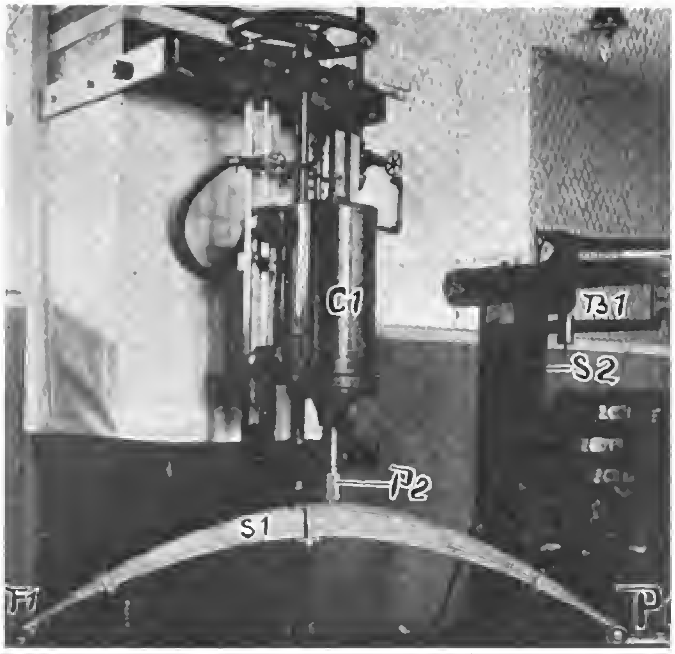

Fig. 12—Spring-testing machine, showing the spring depressed to the limit, and the scales recording the load

FORE AND AFT OSCILLATIONS RECOGNIZED

The general introduction of scroll types of springs followed the recognition of fore and aft oscillations as well as vertical bounce. It was also considered that great flexibility in the vertical plane could be arrived at in two ways, i. e., (a) with long half-elliptic types of springs; (b) with scroll types of springs. It was found that very long half-elliptic type of springs required the use of extraordinary quality of materials, and even then the life of the members was uncertain. Some types were too short in many cases, due, in a measure, perhaps, to the adaptation of inferior grades of materials or to experimental products, which may not have proven to he good.

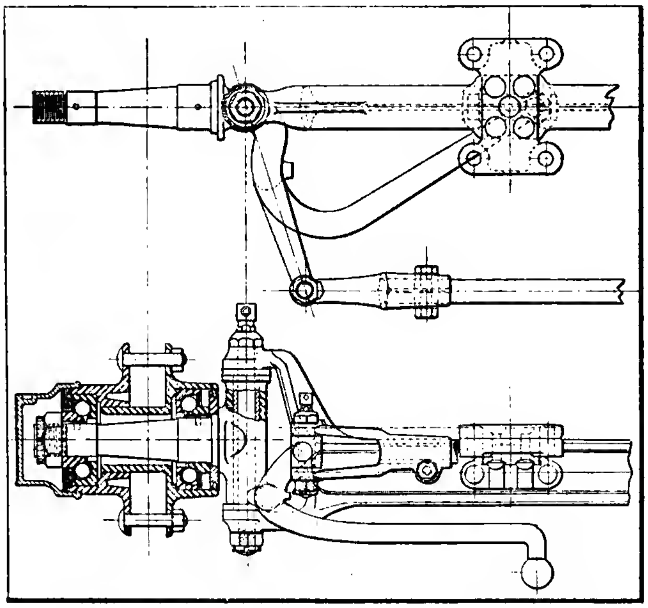

Fig. 13—High section front axle of the Waverley Electric, presenting a well-designed spring perch

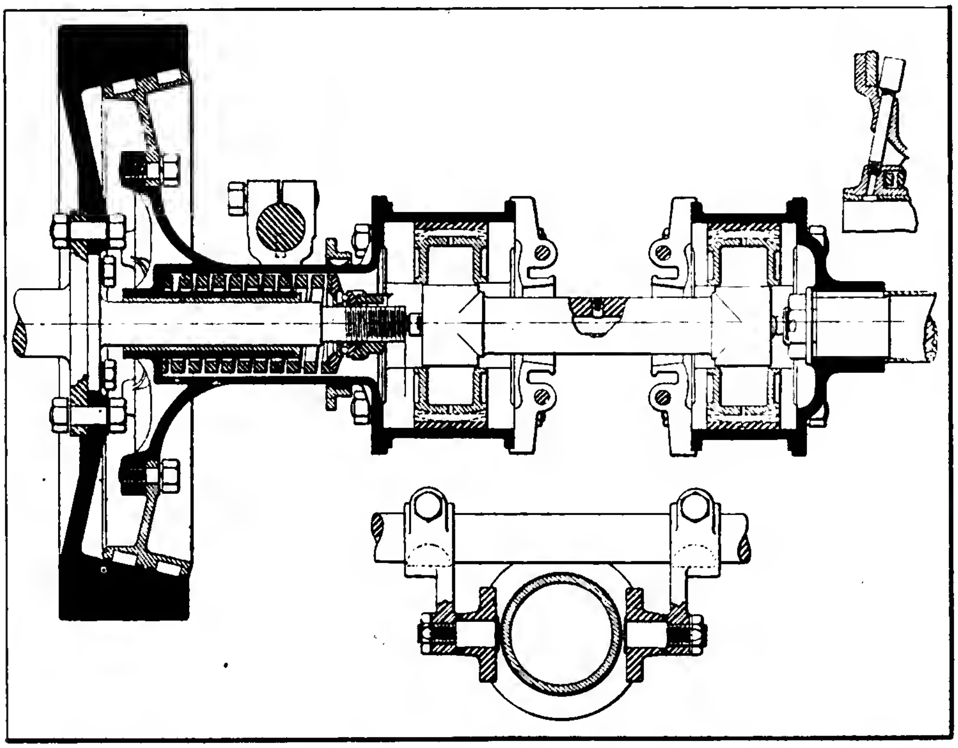

Fig. 14—Alden-Sampson cork insert type of cone clutch with full universal joint connection

Three-quarter elliptic scroll types of springs, as shown in Fig. 8, came into vogue in recognition of fore and aft oscillations and the desire for more easy-riding qualities, with a further expectation that the performance would be soft, and the pendulum effect would improve easy riding qualities. Experience seems to be in favor of the retention of these springs. In rear suspensions in particular full elliptic scroll types are used, they being substantially as shown in Fig. 9.

Platform types of springs, of which there has been a goodly sprinkling for several years, are still much in vogue. They represent extreme flexibility under severe conditions of service, and, in a measure, they are proof of the contention that it takes a certain amount of steel to do a certain amount of work, and realize a full measure of dynamic life of the material present. Fig. 10 illustrates the platform type of spring with the lateral member to the rear—a common practice, but not at all universal. The lateral member is sometimes placed to the front, but full platform types of springs are the exception rather than the rule.

ALLOY STEEL THE PRIME FAVORITE

Some of the earlier efforts, because they involve the use of open-hearth high-carbon steel, were a little less satisfactory than was the wont, brought about through the earlier practices in connection with animal-drawn vehicles. It was soon found that the service demanded of springs in automobile work was of a much more vigorous character than that of the drawn rig, and the kinetic life of the high-carbon steel fell short of the actual demand. In the A. L. A. M. laboratory, and under the direction of outside laboratories, it was ascertained that the kinetic life of steel decreased with increasing carbon, and was lower in embasic products than in acid steels.

With the introduction of vanadium, chromium, nickel and tungsten, under suitable conditions and in appropriate percentages, the fabricators of spring steel were enabled to increase kinetic life in a measure, due to lowering carbon, which was rendered feasible by the introduction of alloying elements.

In the springs, as they actually obtain in the cars which will be on show at the Garden, the generic types of steel may be set down as follows:

(A) Silico-manganese steel, in which the silicon runs about 1.6 per cent., but the manganese is not much higher than that which obtains in other steels of the same carbon content. In this type of steel the carbon covers around 60 points.

(B) Vanadium steel, in which the vanadium is held at a fairly low limit; 18 points or under, the carbon is maintained at substantially 60 points, and chromium may be present.

(C) A tri-alloy steel holding chromium nickel and tungsten with carbon at 60 points.

(D) Specification carbon steel, usually a basic product, with carbon regulated for 100 per cent. pearlite, when the steel is in the normal state. This steel is necessarily from pure ores, and the metalloids are maintained at .03 for sulphur and phosphorus as a maximum.

Spring makers in the manufacture of automobile springs, in view of the hard surface to which the springs are necessarily subjected are equipped in a most elaborate way, this equipment including special gas or oil furnaces provided for purposes of heat treatment, and temperature is regulated with great precision.

The spring plates selected are relatively thin, considering former

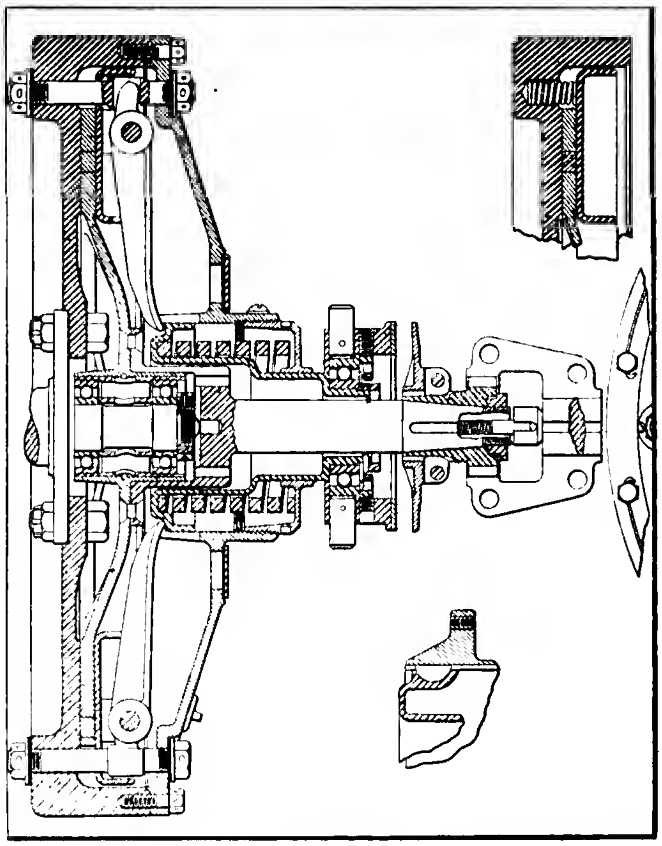

Fig. 15—Thomas flat plate clutch with cork inserts and adequate surface for service.

practice, and the width of the plates is also greater. It is the idea to so design the springs that they will dissipate the greatest possible amount of energy without increasing the fiber strain in the extreme section of the plates to a point which will endanger the life. Unfortunately, it is necessary to design springs so that the fiber strain will be relatively high under normal working conditions. For this reason spring makers have to design in such a way as to limit the increase in fiber strain which will follow when the springs are depressed. In a practical sense, the whole situation is simple enough, since the plan involves the use of wide plates, and the relatively increased number of them, which means thin plates, and these are bowed to a common radius, so that the fiber strain will be the same in every place under normal working conditions.

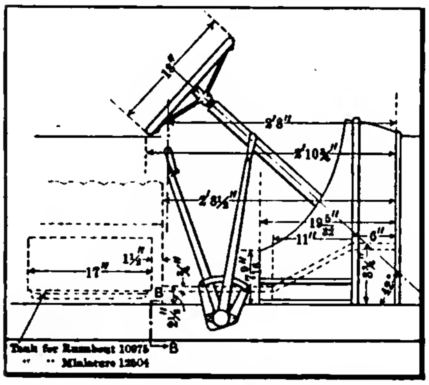

Fig. 17—Pierce-Arrow Runabout type, showing dimensions of body

As a rule the plates are rolled with round edges, and the flat surfaces are concave, so that the plates bear on their edges. This is an excellent idea, partly because it increases the pressure per square inch, and in some measure the friction, but it also affords pockets in which lubricating oil may hide, and, in accordance with the law of the flow of oil, it will migrate upwards to the high points and gradually feed lubricant to the pressure surfaces

SPECIAL SPRING TESTING MACHINES DEVISED

Spring making is an empirical undertaking to a very considerable extent, and skill is necessary to a greater extent than might ordinarily be supposed. In automobile work, in view of the large number of cars turned out, and the importance of good springs, it was found desirable to supplement the personal judgment of the spring-maker by the introduction of testing machines, it being true that the personal equation in connection with the quantity undertaking influences for trouble. Fig. 11 shows a spring S1, on a fulcrum F1, for end of the spring and resting on the platform P1 at the other end of the spring. A hydraulic cylinder, C1, with its means of control, is centrally located so that the piston rod P2 presses against the center of the spring, and the amount of the pressure is recorded on the beam B1 of the scales S2. Fig. 12 shows that the spring S1, under pressure interpreted by the piston rod P2, is straightened out. The amount of deflection may be noted by suitable markings on the piston P2, and the pressure exerted at P1 will show on the beam B1 of the scales S2.

The method of control is perfectly simple, and the piston P2 moves down with great deliberation, thus enabling the inspector to arrive at a fair conclusion of the competence of the respective springs, he knowing beforehand how much they ought to deflect to satisfy the given conditions under which they are to operate. Systems of this character, varying in some slight particulars in different cases, were found in the various establishments devoted to the manufacture of springs, and the makers of automobiles, as a general rule, are equipped for testing springs also, these particular illustrations having been taken for the author at the Thomas plant in Buffalo.

SOME PRACTICAL CONSIDERATIONS FOR THE AUTOIST

In the cars with live rear axles the spring purchases are, as a rule, free to rotate. The springs, therefore, do not have to take a tortional effort of the live rear axle, and a matter of greatest importance in maintenance is to maintain a tight clamping of the springs to the purchase. Fig. 13, which is a front axle of a Waverley Electric, shows a perch with the wings for the U-bolts far enough out to enable the assembler to apply wrenches, and the pressure which may be exerted on the nuts of the U-bolts will therefore be sufficient for the purpose.

In almost every case a leather pad is skived to the proper curvature of the springs where they rest on the purchase (wood is sometimes used), and the pad thus placed serves a double purpose, in that it permits the U-bolts to be drawn up tightly, and, the coefficient friction of the leather or wood being far greater than that of metal to metal, the springs are clamped into secure relation.

DRY PLATE CLUTCHES USED THIS YEAR

While there is a general improvement in clutches all along the line, the fact remains that the one distinct advance, if such it may be called, is in the utilization of dry-plate clutches, of which the new Packard is an excellent illustration. This type of dry-plate clutch differs from multiple disc clutches primarily in the use of from five to eight plates, instead of from 40 to 60 thin discs. The plates are relatively thick, and the friction members are in the shape of "asbestos fabric," which is riveted on to the plates; lubricant is excluded. There are several advantages claimed for dry-plate clutches, among which is the self-evident fact that the bearing surfaces at the splines are much more liberal, and the plates will therefore remain free in their action. It is also said that they do not act "fierce," but that they take a hold gradually, bring the car to maximum speed smartly, and hold in hill climbing under the most severe conditions of surface.

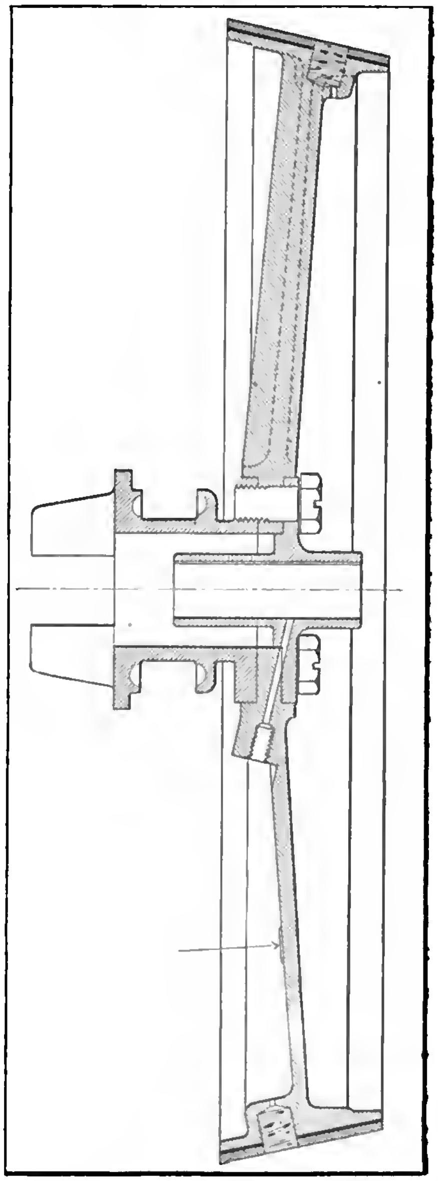

Fig. 16—Section of Pierce-Arrow cone clutch leather faced with cork

Dry-disc clutches are, to some extent, as an evolution;

"cork inserts," as used in some types of clutches, offer substantially the same advantages, and the experience of several years with "cork-insert" clutches seemed to indicate that, in the long run, the absence of a lubricant eliminates a certain class of troubles. Fig. 14, which is the clutch assembly in the Alden-Sampson truck, shows a type of cork-insert clutch which has given excellent service under the severe conditions involved in trucking work, and it is true of this type of clutch that it is not rendered *hors du combat* if a little oil smears over the surface.

Incidentally, Fig. 14 shows some other details which throw light upon some other phases of the commercial problem, as, for illustration, the clutch spring is square and offers close to 1,000 pounds pressure in the engagement of the clutch. The crankshaft flange is of considerable diameter, and the flanging bolts are liberal in size. The bronze bearing on which the clutch is centered and rotates is very long, and a ball-thrust block takes the unbalanced portion of the spring pressure. Back of the thrust block a pair of universal joints transmit the power from the clutch to the transmission gear, and there is evidence of strength and symmetry at every point. This figure rather goes to show that the old stricture, to the effect that commercials were mere adaptations of pleasure cars, no longer holds.

In the Thomas car, as shown in Fig. 15, a three-plate clutch is used, aided by cork inserts. The general scheme of the design is such that the flywheel is faced off to form a bearing for the middle member in the three-plate system. This bearing is far out towards the rim and is relatively wide. The outer member of the plates, which interprets the cam action of the lever system, has an equivalent area, and is made quite thin so that the ills of inertia are eliminated. This clutch, as the suction drawing shows, is engaged through the good office of a stout, square section spring, rolls on annular-type ball bearings, and is adjustable in every way. One very excellent recommendation for this clutch lies in the length of time it has served.

Multiple disc types of clutches are just as much in vogue as in the past, having increased in a ratio which makes it possible to say that they are holding their own. It might even be proper to say that in the low powered cars, in particular, multiple disc types of clutches are well in the ascendency.

Cone clutches are very much improved in every way, they being lighter, hence less likely to impede the sliding of gears, which trouble was, in former times, the real objection to the cone type of clutch. Fig. 16, which represents the Pierce-Arrow cork insert cone clutch, shows a very light but stout design, a rather wide face, covered with clutch leather, and the row of cork inserts, they being staggered around the periphery, registering with the disc structure of the clutch. In this design it seems to be the idea to reduce weight in every possible way, and, as was ascertained in the A. L. A. M. laboratory, the thinner the aluminum the stronger it will be. This is one example of the great utility of aluminum in the hands of competent designers. This material is initially rigid, which is a desirable clutch spider characteristic, and it is amply strong for the purpose, when it is properly dished and suitably ribbed. The inertia of the moving mass is reduced to a low ebb, due to the small value of the specific weight of aluminum as it is alloyed for clutch-spider work, and, coupling this design with a well-directed angle of the cone face, considering the use of a proper grade of friction leather, supplemented by cork inserts, it was a matter of no moment at all as to whether oil smears over the faces, nor will the clutch act "fierce."

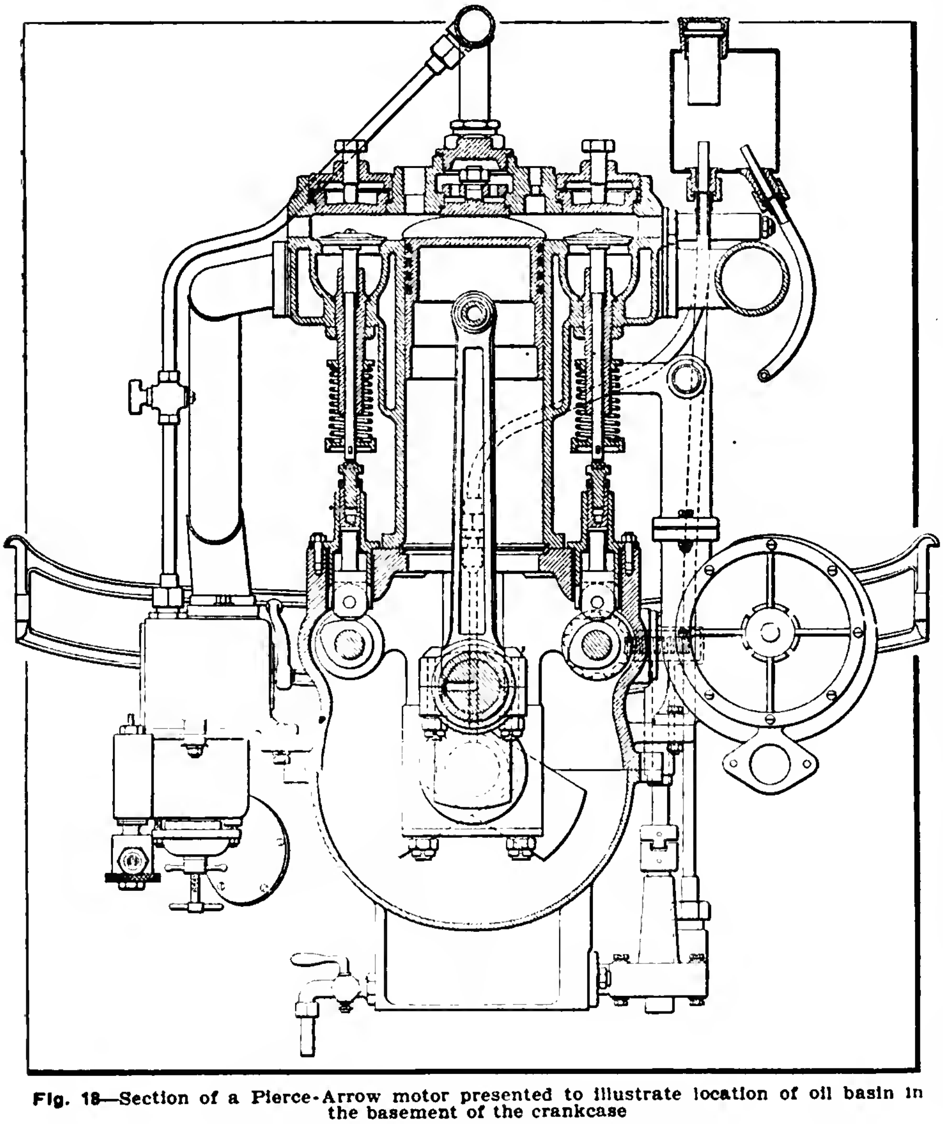

Fig. 18—Section of a Pierce-Arrow motor presented to illustrate location of oil basin in the basement of the crankcase

MOTOR DESIGNS ON A STABLE BASIS

Perhaps it will be of the first importance to point out that, to a very considerable extent, gray cast iron is being used in motor cases, especially in the smaller sizes of motors, to the exclusion of aluminum. This departure from a former fixed practice is due in some measure to uncertainties in aluminum, and again to the improvements wrought in gray iron work, which permits of the use of relatively thin castings, so that, for a given weight, it is actually possible to substitute cast iron, although its specific weight is approximately three times.

In the larger and more pretentious automobiles it is still the custom to use aluminum, and this material probably will be continued, certainly until something better is found, but every effort is made to employ pure grades of aluminum in the process, eliminating scrap, and preventing contamination in the foundry. The shapes of crank cases in silent-performing cars are looked after with the utmost care, and thick walls are used to prevent noise. Cylinder castings are now so thoroughly well made, and of such fine grades of material, that the results are thoroughly good.

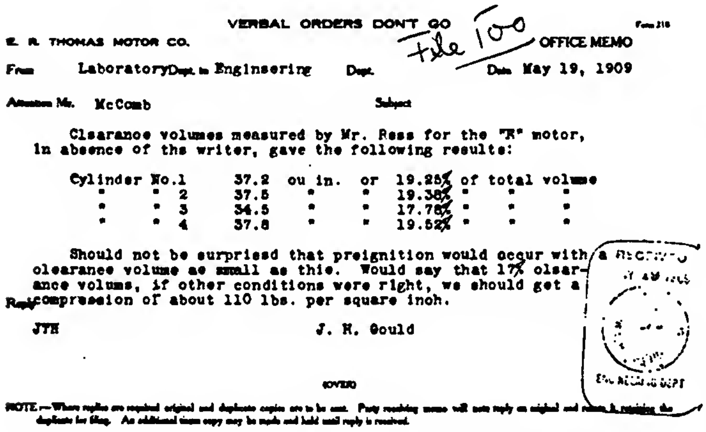
· Precision · in · Production · the · Theme ·

· By · Thos · J · Fay ·

ASSOCIATION for the common good which is the idea of the A.L.A.M., must, if anything, lead to precision of production, which, if it results in standardization of manufacture, ends in interchangeability of parts. Quality, under such conditions, will be at a fair price. This question of quality, as it relates to price, is a matter of the gravest concern, inasmuch as a machine may be extremely high in price, yet low in the scale of utility, showing that price is not all.

If the methods in vogue in a shop obtain in the absence of suitable instruments of precision, or, if the machine tools are of an antiquated vintage, then bench hands will have to be depended upon for results, and, while these may be men of skill and judgment, still they will not be on an exact par with each other, and the output from them will fall below any reasonable standard, even under conditions of liberal limits of tolerance.

If the machine tools are of the class which once served very well, so to speak, in the manufacture of machinery of the kind built up principally of cast gray iron, with perhaps machine steel as the hardest material to work up, then the tools will not be sufficiently rigid for the newer work, and accuracy will fall off in proportion as the tools deflect under the work.



VERBAL ORDERS DONT GO

E. R. THOMAS MOTOR CO. — OFFICE MEMO

File 100

From Laboratory Dept. to Engineering Dept. Date May 19, 1909

Attention Mr. McComb Subject

Clearance volumes measured by Mr. Ress for the "K" motor, in absence of the writer, gave the following results:

Cylinder No. 1	37.2	cu. in.	or	19.28%	of total volume
" " 2	37.5	"	"	19.38%	" " "
" " 3	34.5	"	"	17.78%	" " "
" " 4	37.8	"	"	19.52%	" " "

Should not be surprised that preignition would occur with a clearance volume as small as this. Would say that 17% clearance volume, if other conditions were right, we should get a compression of about 110 lbs. per square inch.

NOTE.—Where replies are required original and duplicate copies are to be sent. Party receiving memo will note reply on original and return it, retaining the duplicate for filing. An additional tissue copy may be made and held until reply is received.

Fig. 1—Form of laboratory report used in E. R. Thomas plant to assure precision

If instead of a laboratory, rule of thumb methods have to be relied upon, it follows that the materials purchased will be up to the standard of the furnisher thereof and it may be that this standard will be lower than the aspirations of the purchaser.

If the designer of an automobile or parts locks himself up in a room; fails to take heed of the progress being made around him; inveigles himself into the belief that he has a monopoly of brains, and endeavors to purchase all the "cardinal virtues" in the simple process of paying workmen $15 per week to do his bidding—it is not supposable that the automobiles, if such they may be called, will compare favorably with the class designed and built after the undertaking has had the advantage of the enlightenment emanating from associated engineers, who, in turn, must satisfy the business establishment in all essential particulars.

INDIVIDUALITY IS NOT STIFLED IN THE PROCESS

The willing horse, the genius, and the innovator, all representing the graces of the engineering office, will still be there, and they, being irrepressible, will chafe in gear until their claims of better things find a safe abiding place in the maw of the management, and it is not likely that a real improvement can be resisted for long. In combining effort, it is possible to see advantage, especially when reference is had to innovations, for by this very association the members are enabled to keep abreast of the situation; feel the pulse of the supporters; determine merit, and ascertain the best way to launch a new idea.

In view of the close association of the exhibitors (the Association of Licensed Automobile Manufacturers), and in connection with a comprehensive discussion of the automobiles, as they will appear in Madison Square Garden, New York, it will be more to the point to review methods in vogue in the shops, taking an example here and there, rather than to write about some one shop. In this way, there can be presented a "birdseye view," reflecting, in measure, the inherent qualities of the products as a whole, leaving it to purchasers to ascertain for themselves the particular points of merit in the respective cars which appeal most to them.

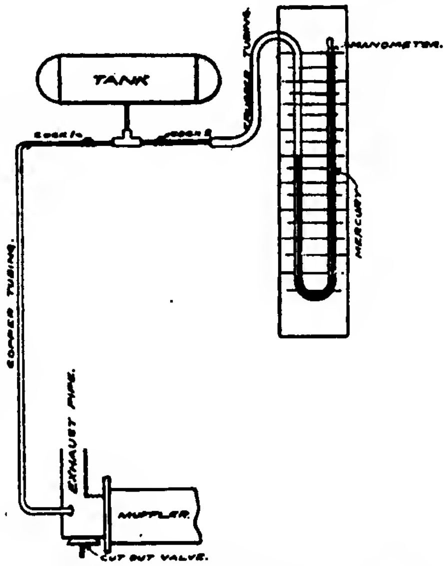

Fig. 3—Plan contrived to test mufflers on the road under regular conditions of service

SOME EVIDENCES

In order to fully appreciate the advantages of association, it will be necessary to illustrate clearly the points to be made. Table I affords enlightenment as to the front area of radiators as they are used on several of the well-known makes of automobiles, this data having been compiled in the laboratory of the E. R. Thomas Motor Company, Buffalo, N. Y. In order to keep out confusion, in this laboratory, all orders are given in writing and answers must also be in writing. One is reproduced here in Fig. 1. This report, requiring no further explanation, holds information of a character which should be noted. It reveals two things to the reader, one of which is that the clearance volume in motor cylinders, unless they are most carefully made, will not be alike in all. In addition, the question of pre-ignition is a live matter.

EFFECT OF ANNEALING ON SIZES OF CYLINDERS

In annealing cylinders, in order to relieve strains which are likely to reside in them as they come from the foundry, a new source of trouble confronts the designer, and in order to ascertain the extent of deformation in the annealing process the test, as

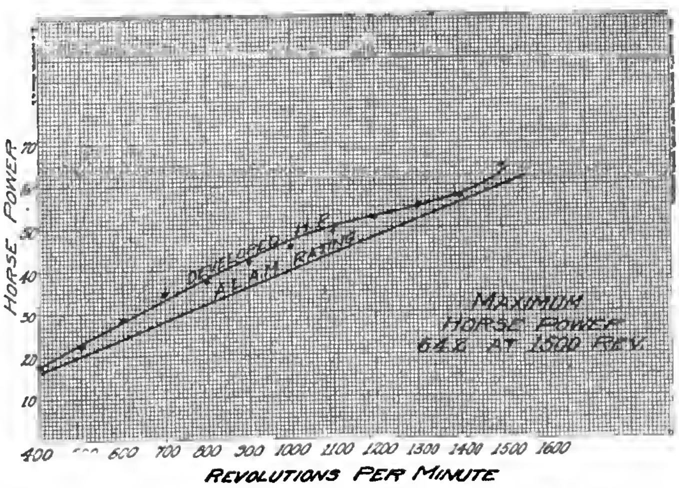

Fig. 2—Model M Thomas motor which exceeds A.L.A.M. rating as the curve shows

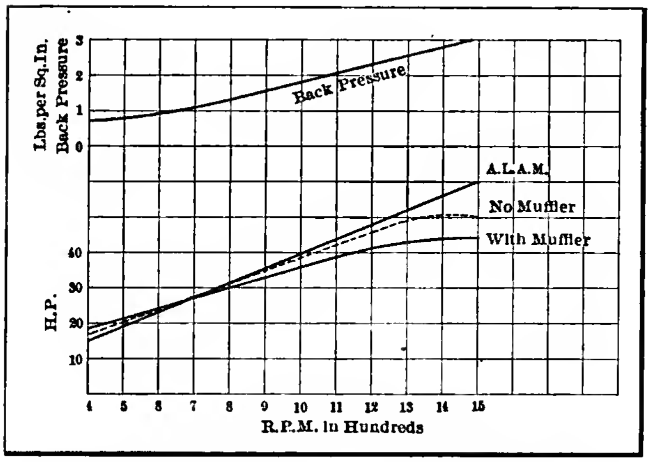

Fig. 4—Curve showing how curve of back pressure falls away under high speed

here given (see Table II), was made in the Thomas laboratory. A study of the table will disclose considerable variations, and the results suggest that annealing must be done before cylinders receive the finish bore. This annealing process, as the author now sees it, indicates to a degree the extent to which internal strains reside in cylinders as they come from the foundry. If this is so, annealing is necessary for the best results, it being proper, apparently, to choose the propitious time for the process.

THOMAS MODEL "M" MOTOR PERFORMANCE

Perhaps there is no better illustration of the value of exact methods than that of the curve of performance of the Mdoel "M" Thomas motor, in which, as the curve Fig. 2 shows, the power of the motor, which is a "six," exceeds the A.L.A.M. rating at all points in the speed range between 400 and 1,500 revolutions per minute. The same curve also shows an upward tendency from 1,400 to beyond 1,500 revolutions, and it would be interesting to have the results of a further investigation of this phase of the test; perhaps the results may be had at some later date, when the carbureter problem is followed to its ultimate conclusion, it being the case, in all probability, that the change noted (in the curve) is one involving carburetion.

INVESTIGATING BACK PRESSURE IN MUFFLERS

If a pound per square inch is equal and opposite to a pound per square inch of back pressure, this back pressure, due to the use of a muffler, is a very serious matter, and the Thomas company, appreciating this, investigated quite a number of mufflers for the purpose of finding a solution to the difficulty. One very interesting test, made with a car on the road, required the use of an equipment, a diagram of which is given as Fig 3, and the report of the engineer who conducted the test:

TEST OF A REED EJECTOR MUFFLER

"This special Reed ejector muffler has been used on all the K cars since August. One of the load test cars was fitted with a small pressure tank and manometer, as shown in Fig. 3, and in the top of the body of the muffler cutout a small hole was drilled and tapped for 1-8-inch pipe union. A 5-16-inch O. D. copper tube was used to connect the muffler to the tank. Proper valves were provided, as shown, and the manometer mounted vertically on the dash. Mercury was used as a means of measuring the pressure, the manometer back being calibrated to read inches. The object of using the tank was to act as a reservoir until the pressure could be measured. The car was equipped with a Warner 100-miles-per-hour speedometer. The throttle quadrant was graduated into eight divisions so as to form an index of throttle openings.

"The tests were made near Williamsville. With a given throttle opening when the car had arrived at a certain speed and had remained so from 30 to 40 seconds, the valve was turned off, thus entrapping the gas in the tank at the same pressure that had previously existed in the exhaust chamber during test. The car was then brought to a stop and reading of the manometer taken. The different speeds with constant throttle opening were obtained by either running the car uphill or holding it down with the brakes. Tests were made at every eighth until full throttle was reached. Similar tests were made with the muffler cutout to bring out the difference in performance."

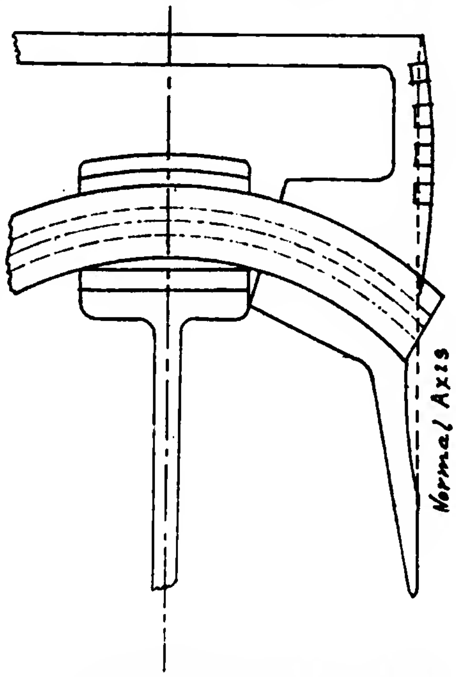

Fig. 6—Diagram devised to show how pistons deform when pressure is applied

As one of mercury equals 0.49 pound per square inch, then, by multiplying the manometer reading by this factor, we reduce to pounds per square inch.

From the data obtained curves were drawn, and it will be seen that the back pressure depends upon the throttle opening (*i.e.*, the amount of gas passing) as well as upon the velocity. Fig. 4 shows that 73 miles per hour for 3-4 opening, the curve rounds over. At this speed the car was running downhill. The engine speed was so high that the combustion was imperfect, thus producing less exhaust pressure.

The car was driven on high gear during tests:

Bevel pinion on main drive shaft	30 teeth.
Bevel gear on jackshaft	45 teeth.
Drive sprockets	30 teeth.
Driven sprockets	48 teeth.

which makes the gear ratio 2.4 to 1.

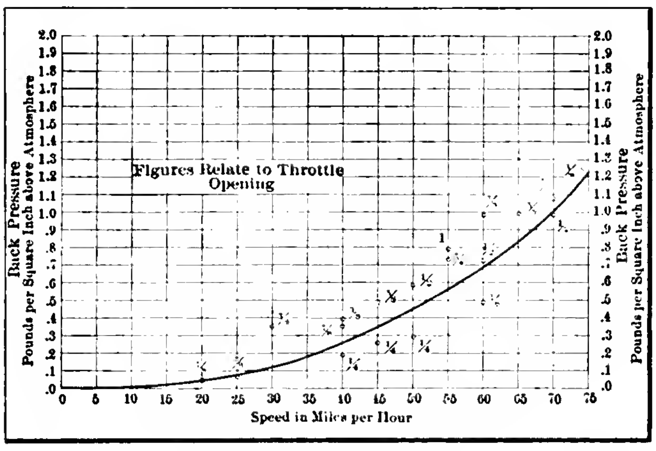

Fig. 5—Curve of back pressure when an inefficient muffler was substituted for that of Fig. 4

"It will be noticed that the first position for curves, 1-8, 1-4 and 3-8, are low, which would bring the intersection of the curve with the speed axis at a point before zero. As to whether this is correct or not, cannot be determined without further testing.

"With the muffler cutout data obtained curves have been plotted and a curve showing in a very general way the increase of back pressure with increase of speed due to opening the throttle on the level."

MUFFLER DEPRESSES POWER DELIVERY

By conducting a series of experiments on various types of mufflers in connection with a Thomas motor, it developed that power is materially reduced if the muffler offers much back pressure, and Fig. 5 is a curve of results of one of these experiments made by using a somewhat inefficient muffler for the purpose. Fig. 2 was given to prove that Thomas results are better than A.L.A.M. ratings, whereas Fig. 5 presents contrary evidence in that the power delivered by the particular motor used in this test fell well below the A.L.A.M. rating when the back pressure due to the muffler used was increased, whereas the Reed ejector muffler regularly used in Thomas work offered no such resistance to the flow of the exhaust.

Table III, which is given in this article, shows some of the series of readings taken in the road test, from which the curve Fig. 4 was plotted. This series of data will help materially in the process of following up the test, especially if the reader is not skilled in such reading diagrams as Fig. 4.

PISTON DEFORMATION UNDER LOAD CONDITIONS

Considering perfection of design of automobile motors the end is not as yet, and this is to be looked upon as a hopeful sign rather than with a despairing eye. In order, however, to advance the work, facilities, inclination, and time in which to accomplish the tedious tasks must be available. As an indication of the underlying situation, refer to Fig. 6, which shows, theoretically, and in an accentuated manner, how pistons do deform in service, and, as to the extent of this deformation, it is enough to examine Table IV, connected with the report of the test, in conjunction with the report of J. M. L. Howe, of the E. R. Thomas staff, as follows:

HOWE REPORT OF PISTON DEFORMATION

The idea in this test was to determine under various loads the distortion of the piston from a true cylindrical form. A straight ground piston of .003 clearance was used and measurements taken as follows, both at an angle and parallel to the piston pin of the four bridges, and space between clearance and fourth bridge. The lower portion of the piston was measured in two places, *i.e.*, near the top and near the web. Wristpin clearance groove is 1-2 inch.

A wristpin and straight connecting rod were used. Then the crankshaft bushing on the rod (a short piece of shafting) was slipped and box tightened up. The piston and rod were next put under a 30-ton hydraulic press, the piston being up and a piece of blotting paper being interposed between the piston head and the plunger. The shafting was supported by two V blocks. Care was taken that the axis of the combined piston and rod coincided with that of the plunger. This is a fine illustration of the futility of theorizing in a garret and building on paper; it takes facilities, experience and persistence if the product is to be thoroughly good in every way.

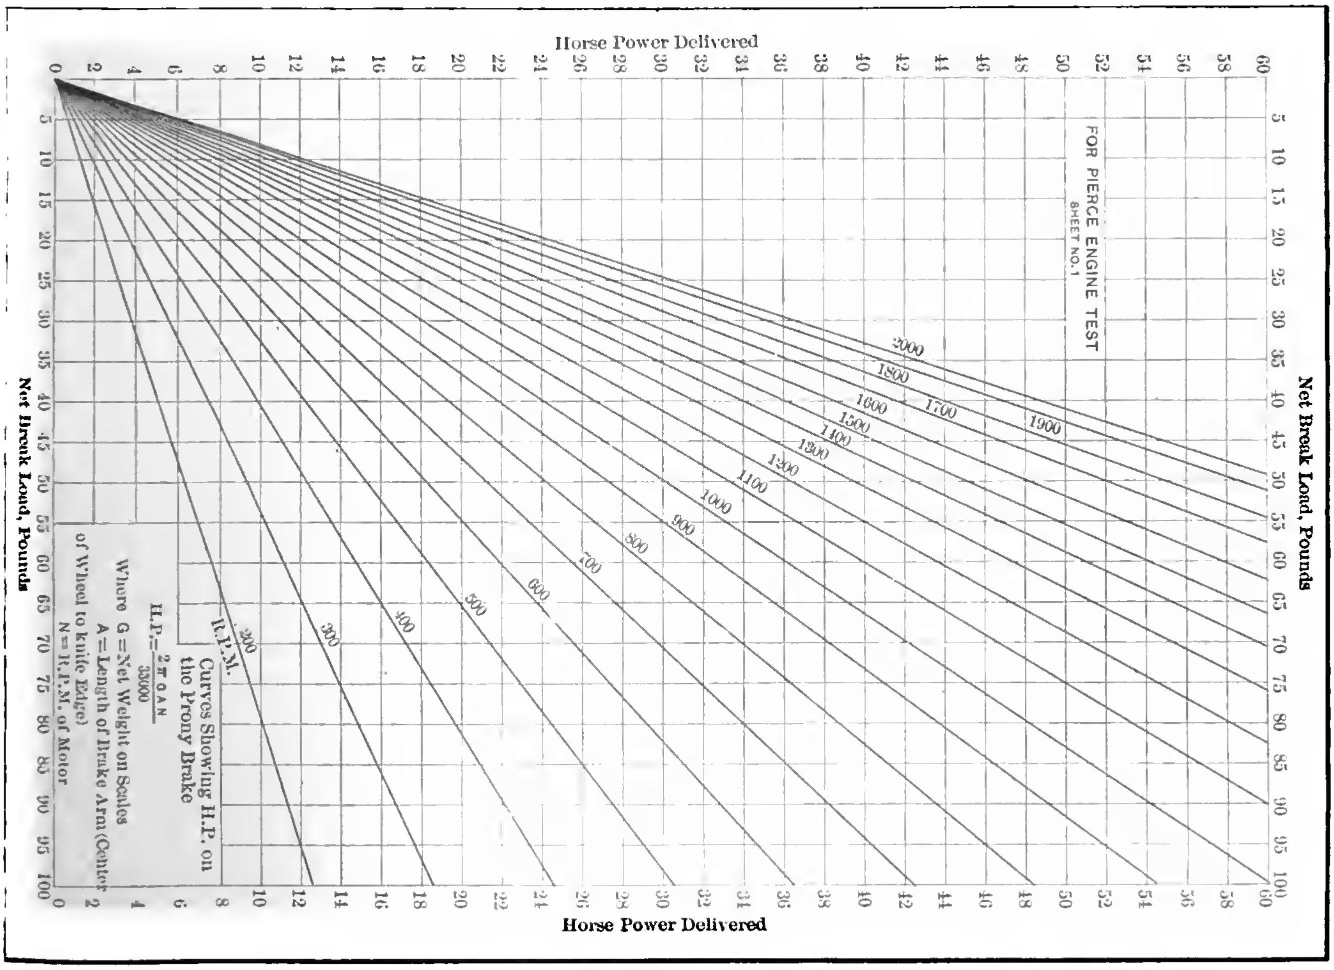

Fig. 7—Chart contrived for convenience in testing motors, showing horsepower at various speeds and brake loads

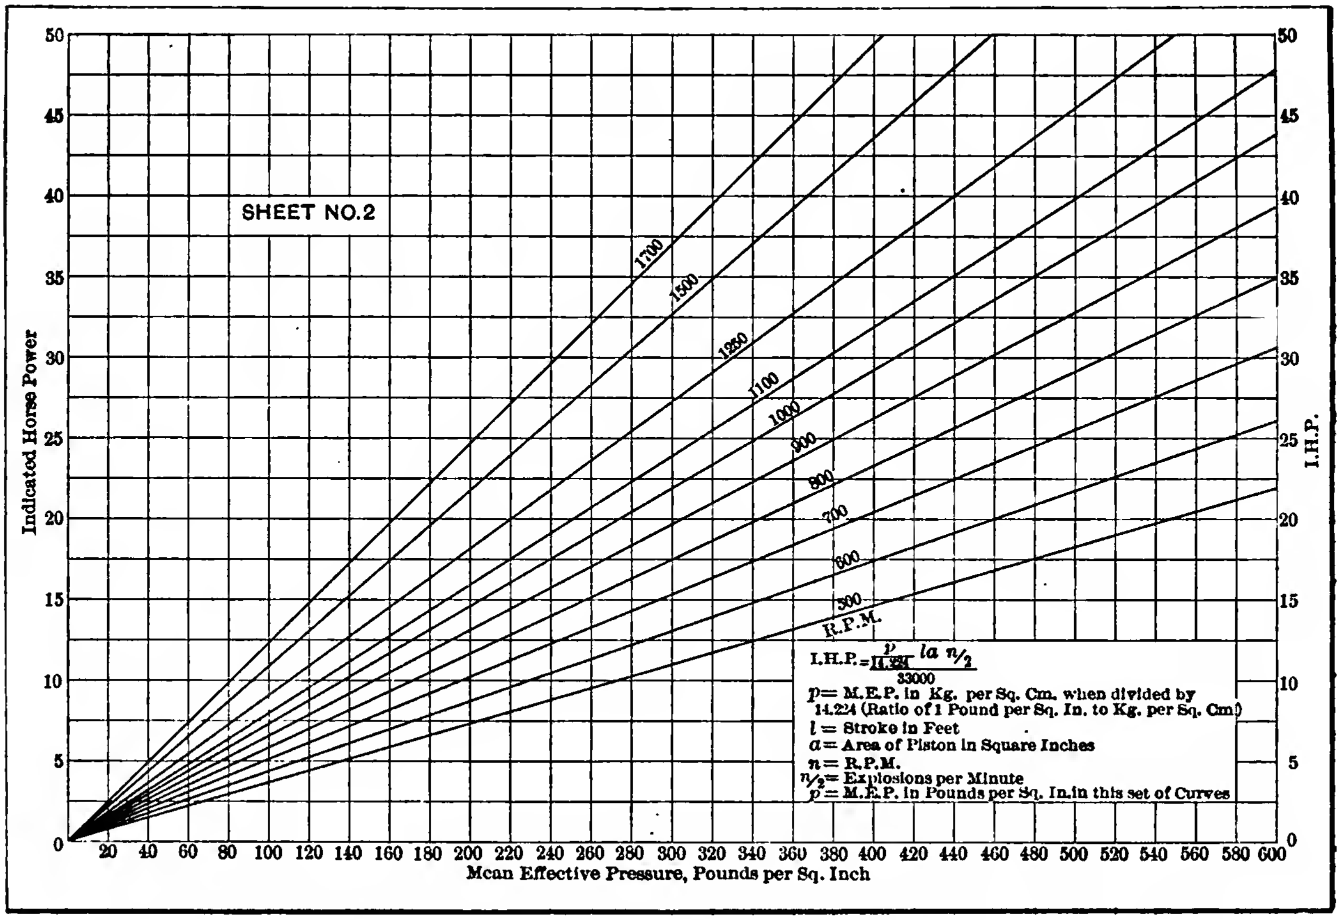

Fig. 8—Chart contrived to show mean effective pressure under different loads as measured in indicated horsepower

The claim is frequently made that a piston is lighter than all others; it is ribbed, or it is without ribs, and that the fit is within some fraction of a thousandth of an inch. If the ribs are not properly placed, or if the walls are not suitably designed, there is every likelihood that warping will be far in excess of any allowed fit allowance and the piston will stick in the cylinder every time it reaches the top of the stroke, in which event the result will be disastrous, and it is in this way that many of the failures of the past can be readily traced. There are divers points of this character to be settled in connection with proper designing, and it is a serious question if the work can be properly done in the absence of tools devised for the purpose and in the hands of men of proven competence.

A weight of two tons was applied and piston measured up while under pressure. This gives the maximum explosion load approximately as from the manograph cards on the "L" motor. The maximum explosive force was from 375-400 pounds to square inch of piston area.

$$P_m \times A = \text{force of piston.}$$
$$= 400 \times 3.625^2 \times .7854.$$
$$= 4{,}140 \text{ pounds.}$$
$$= \text{approximately 2 tons.}$$

The results are shown on the data sheet. It will be noticed that the cylindrical form of the piston is changed to an ellipse with the major axis parallel to the piston pin, or, in other words, the axis of the piston pin and the major axis of the ellipse lie in the same plane for above pin. The greatest deformation of decreased diameter occurs at portion between fourth bridge and wristpin clearance. The positive deformation lessens from here to top of piston. In space below clearance the deformation is slightly negative and the axis of the deformation has swung to one side slightly, but at portion near web the axis again assumes parallelism.

Next, a load of 5 tons was applied and measurements taken. These measurements show the characteristic distribution as previously given, but are increased about directly proportional to the load, *i.e.*, 2 to 5.

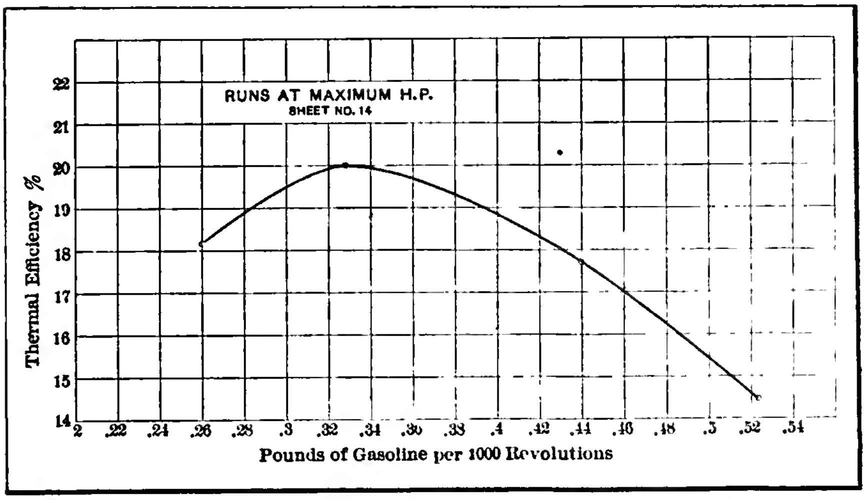

Fig. 9—Curve of thermal efficiency with a motor running at maximum load in horsepower and a speed of 1,000 revolutions per minute

The pressure was next carried up until the connecting rod collapsed, as shown. The pressure was approximately 7 tons, which gives a factor of safety of 3 1-2. The rod failed at what is known as the "square"-ended column failure," which means that the two ends were fixed in contrast to a pin-ended column. The connecting rod, if it had failed in a plane at right angles to the piston pin, would have failed in a "pin-ended column." It is a peculiar fact that the square-ended column is four times as strong as a pin-ended one. The failure in actual practice, if these excessive pressures were used, might lie in a plane at right angles to the present failure, due to the whipping or inertia forces which are added to the piston load.

The permanent deformation of the piston is given. It will be noticed that the major axis now runs at right angles to the pin. On taking the wrist pin out it was found to be bowed upwards approximately .02 inch. The wrist pin is made of 3-4-inch x 3-16-inch wall steel tubing, 3 7-16 inches long, hardened and ground down to .7192 inch.

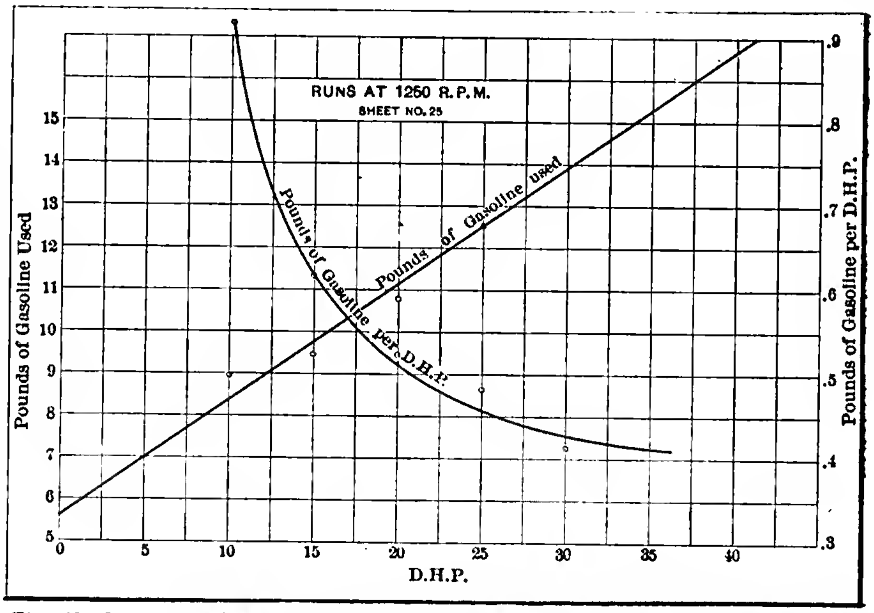

Fig. 10—Curve showing fuel per delivered horsepower and total fuel used under different conditions of power

For a theoretical consideration on strength of wrist pin, the custom is to treat it as a beam held at both ends and loaded at the middle instead of by a uniform load. The reason for the deformation is shown by the following sketch. As the piston pin bends, the walls of the piston, being very light, are forced outwards, and the walls below the pin inwards. As tests have been made on the heating of the "L" cylinder and piston, and these tests have shown that there is no appreciable deformation, the cause of scoring is due to weakness of the wrist pin.

Proper webbing in plane at right angles and perpendicular to pin across head and following down to bosses would greatly decrease deformation.

WITHIN THE PIERCE-ARROW LABORATORY

While there is a certain similarity between the laboratories in the several automobile plants, it remains that severally specialized methods prevail in them to a vast extent. As to these methods much depends upon the progress previously made and there is something to be attached to the objects sought. Characteristic of the line of investigation conducted in the Pierce laboratory, or in connection therewith, is the system of motor investigations pursued for the express purpose of ascertaining the exact facts in relation to fuel economy, power of range and flexibility.

Referring to Fig. 7, which is a curve plotted to show horsepower on the Prony brake, it will be observed that by a series of diagonal lines, each one of which represents some one speed of the motor, they, in conjunction with ordinates reading "net brake load in pounds" and "abscissa," afford a means for determining the horsepower of the motor at any one of the respective speeds when the net brake load in pounds is known. Referring again to the figure and to a net load of 90 pounds, the point of intersection of the speed diagonal representing 1,100 revolutions per minute is at the abscissa line representing 60 horsepower. In other words, if the motor during test shows a pull of 90 pounds on the brake arm when the speed of the crankshaft is 1,100 revolutions per minute, the motor will be delivering 60 actual horsepower. By proceeding as above for any other pull in pounds at any other speed the actual horsepower delivered may be determined quickly and without calculation, the chart being sufficiently extended to cover the whole range of performance for any motor.

When a manograph is used for the purpose of investigating the condition of the motor, the manograph readings, suitably interpreted, may be resolved into indicated horsepower. However, this information is of small value in the absence of more

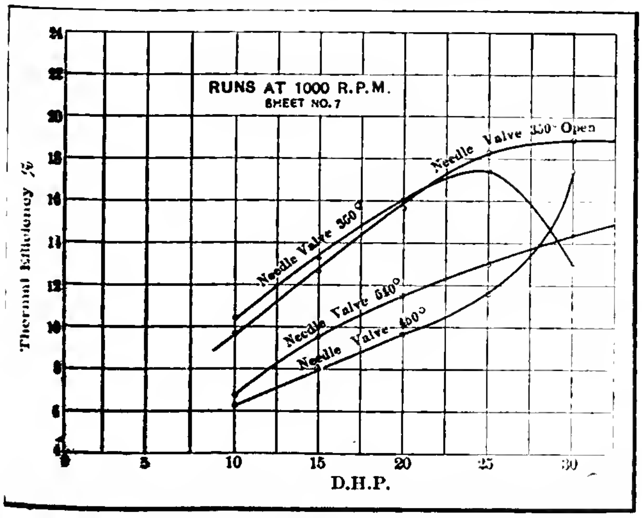

Fig. 11—Series of curves showing performance at different needle valve adjustments and effect on thermal efficiency

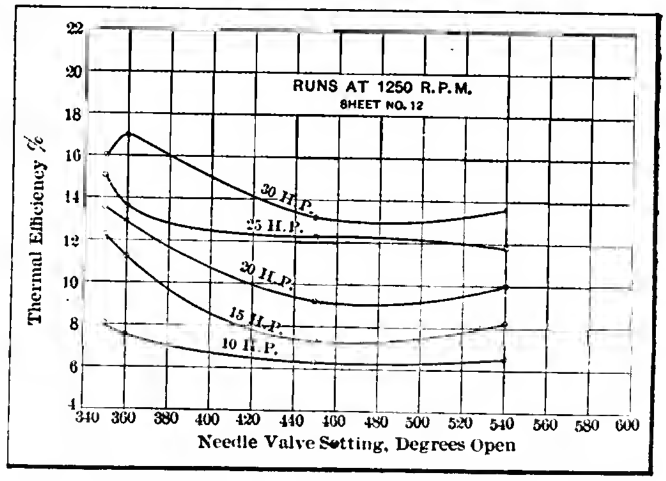

Fig. 12—Thermal efficiency under different conditions of carburetion and for different conditions of power

Fig. 13—Tire-testing machine as used in the Woods plant at Chicago for testing out tires

or less exact knowledge of the pumping losses in a motor. Figure 8 was contrived for convenience in testing Peerless motors. This chart will give, at a glance, the mean effective pressure in pounds per square inch, provided the indicated horsepower is known and by considering the speed of the motor at which the power may have been developed. The diagonal lines represent crankshaft speeds and the abscissa are given in terms of horsepower so that the mean effective pressure will be found as ordinates in the chart. Taking 40 horsepower for illustration, and following out to the point of intersection of the diagonal line representing 1,250 revolutions per minute, it will be found that the ordinate has a value of 440 which is given as mean effective pressure in pounds per square inch.

High Thermal Efficiency Ascertained—Perhaps Fig. 9 will show a condition which is beyond the belief of the old time engineer, who may not have followed closely investigations which were conducted by automobile engineers within the last ten years. As the chart shows, the curve of thermal efficiency, under conditions of maximum power for the particular motor, is maximum at 20 per cent. with the gasoline consumption at about .326 pound per 1,000 revolutions of the crankshaft. This thermal efficiency was unheard of in any other type of power-delivering machine and was not approached in internal combustion motors until refinements were made in automobile types—unless it be remembered that the Diesel type of internal combustion motor has delivered some noteworthy results.

Since the motor in this test was run at maximum power, it follows that the thermal efficiency varied with the gasoline consumption, bringing out very clearly the information which should be of the most use to the average autoist, *i.e.*, that there is only one right mixture, and that fuel economy is maximum when the motor is delivering its best power. This curve gives a wide range of fuel consumption, showing that the thermal efficiency fell to the low level of 14 1-2 per cent. when the fuel consumption was .532 pound per 1,000 revolutions; the thermal efficiency fell away as the amount of fuel used decreased below .325 pound per 1,000 revolutions and a decrease in thermal efficiency when the fuel is in excess or if the mixture is weak.

Relation of Gasoline Used to Fuel Economy—In still another test conducted on the same Pierce motor the data when tabulated and then plotted on a curve as shown in Fig. 10, brought out some interesting points involving the relation of the total fuel used to the gasoline per horsepower. The curved line in this chart reads "pounds of gasoline per delivered horsepower" and the amount of gasoline used decreased as the power of the motor increased, so that, considering a constant speed of 1,250 revolutions per minute, the least amount of fuel per horsepower was found when the power increased beyond 35 horsepower. The straight line in the curve shows that the gasoline consumption increased as the power of the motor increased. This is as it should be, but the point is made here in effect that the position of the diagonal line in the curve is very materially influenced by the decreasing rate of fuel consumption with increasing power.

Influence of Carburetor Needle Valve—Before departing from this phase of the subject, it will be the purpose here to reflect something more which can be construed as having a practical value to the average autoist. A needle valve when placed in the nozzle of a carburetor is there for the purpose of regulating the flow of gasoline. Through its agency the mixture can be made rich or lean at will. It frequently transpires that autoists find themselves in deep water after making a needle valve adjustment. They probably fail to appreciate just what it means to alter the relation of gasoline to air. Furthermore, it has been found that mere discussion falls short of the necessary explanation.

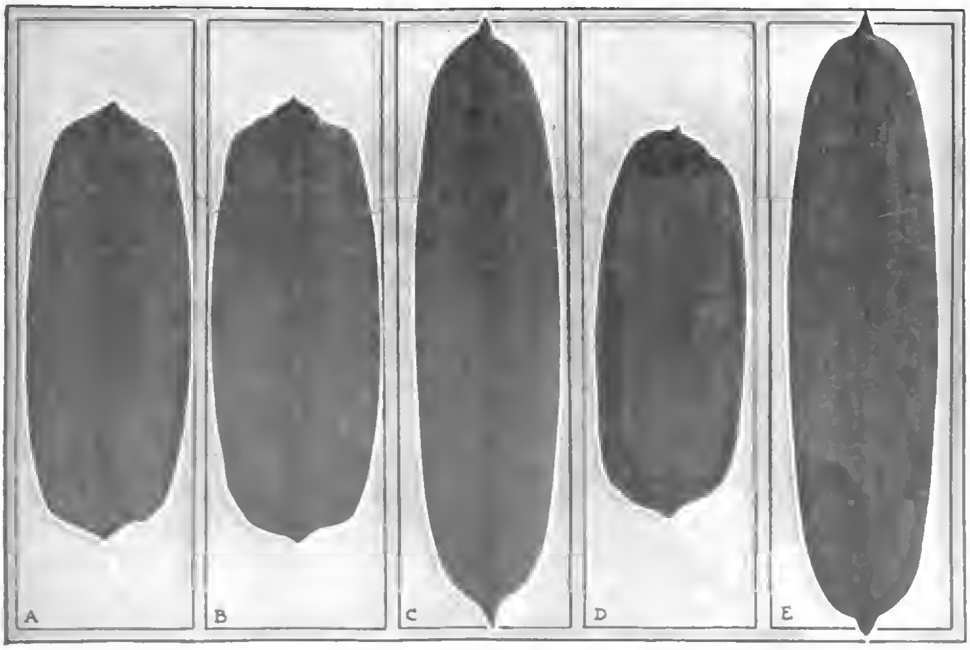

Fig. 14—Presents a set of records from the Woods tire-testing machine, giving information as to contact area under different conditions

Fig. 11 shows variations in thermal efficiency, in view of variations in power, considering different positions of the needle in the nozzle of the carburetor. The several needle valve adjustments are referred to in degrees. To be explicit, the needle was turned 360, 540, or to other positions as stated in degrees, and a curve of performance is given for each of the needle positions. The best performance noted in Fig. 11 is for the opening given as 350 degrees. The thermal efficiency resulting from the test was maximum at 30 horsepower of the motor. With the 360 degree position of the needle the performance was that which would indicate a condition of easy stalling of a motor in the hands of the average autoist; the motor with this adjustment would deliver a little more power at the lower range due to an enriched mixture, but the thermal efficiency falls away rapidly with increasing power and drops to substantially two-thirds of its best value, between 25 and 30 horsepower.

It has been shown that the power changes with the thermal efficiency and that the thermal efficiency as shown in Fig. 11, with the 360-degree needle valve adjustment would be, in all probability, attended by a change in power. Referring to Fig. 12, a means is at once afforded for checking the relations of thermal efficiency to power for different adjustments of the needle valve.

The information thus far afforded in connection with Pierce work is sufficient to indicate, in part, the extent to which matters of this sort are pursued in the well-equipped establishments devoted to the manufacture of automobiles.

TIRE PROBLEMS INTELLIGENTLY COPED WITH

Experimental investigations in wide extent have been carried on in several establishments. In view of this, it is a little difficult to sort out a few of them which can be included in a limited talk on the subject. Consequently it will be the idea here to "touch and go," as it were, for the purpose of presenting a widely diversified situation. Fig. 13, for illustration, presents a tire-testing machine, devised by F. J. Newman, Chief Engineer of the Woods Electric Vehicle Company, Chicago, used by the

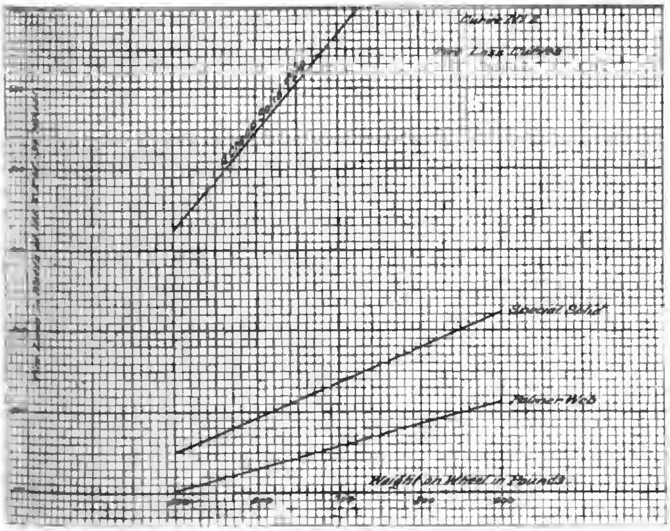

Fig. 15—Curve showing the tire loss in watts under differing load conditions

company for the purpose of determining tire losses and life. In this machine the tire to be tested T_1 is mounted upon its wheel W_1 and presses against a wooden wheel W_2. The wheel T_1 is mounted on a shaft and a pulley, P_1, being mounted on the same shaft, is driven by a belt B_1 which takes its power from the pulley P_2, the same having connection with an electric motor which is the source of power. On the same shaft with the wheel W_2 a brake drum B_2 is placed and brake shoes B_3 and B_4 are arranged to fit over and be clamped against the drum B_2, so that the Arm A_1 measures the force of the twisting moment which will be exerted through the brake drum B_2, which force is interpreted in pounds on the platform of the scales S_1

Since the wheel W_1, on which the tire T_1 is placed, is provided with an adjustment in order to vary the distance between the tire and the drum W_2, it is possible to increase or decrease at will the force which will be exerted between the tire T_1 and the drum W_2. Since the tire T_1 is driven by the belt B_1, over the pulley P_1, the drum W_2 must be rotated by traction against the tire T_1. The amount of the traction will therefore be registered on the scales S_1, through the brake arm A_1 and varied by altering the clamping of the brake shoes B_3 and B_4 against

By painting the surface of the wheel W_2 and pressing the tire

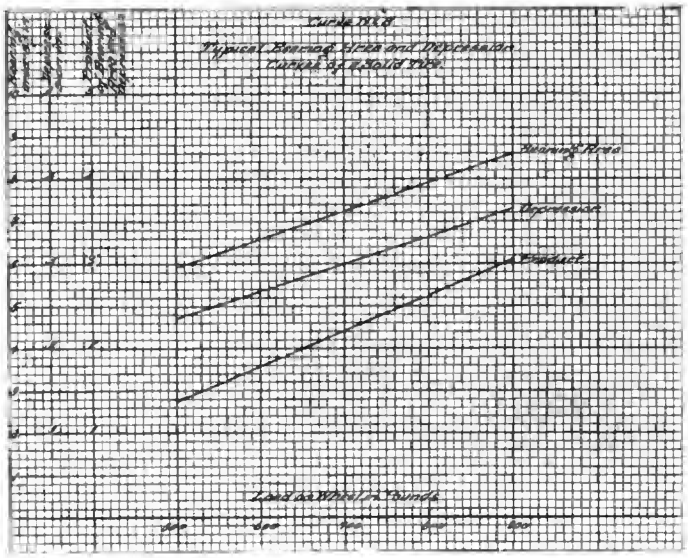

Fig. 16—Curve interpreting data as procured in connection with tests made on tires at the Woods plant

T_1 against the painted periphery of the wheel, it is possible to measure the area of contact of the tire being tested, since a piece of paper slipped in between will receive paint over the surfaces of contact and make a permanent record—which record will be characteristic of any particular tire under a given condition of inflation and for a given pressure. Since it is not the purpose at this time to reach conclusions in relation to tests of this character, it will be sufficient for the present purpose to reproduce tire contact records as shown in Fig. 14, *A*, *B*, *C*, *D* and *E*, they representing tires as follows:

(*A*) Represents an endless solid tire showing 6.8 square inches area of contact.

(*B*) Represents an endless solid tire, showing 7.1 square inches area of contact.

(*C*) Represents an endless solid tire, showing 8 square inches area of contact.

(*D*) Represents an endless solid tire, showing 8.5 square inches area of contact.

(*E*) Represents an endless solid tire, showing 5.65 square inches area of contact.

It will be seen that the performance, when reference is had to tires from the point of view of life and energy consumed, will not be the same when all of the tires do not flatten the same amount under a given load and other equal conditions of the tire on the periphery of the brake drum B_2.

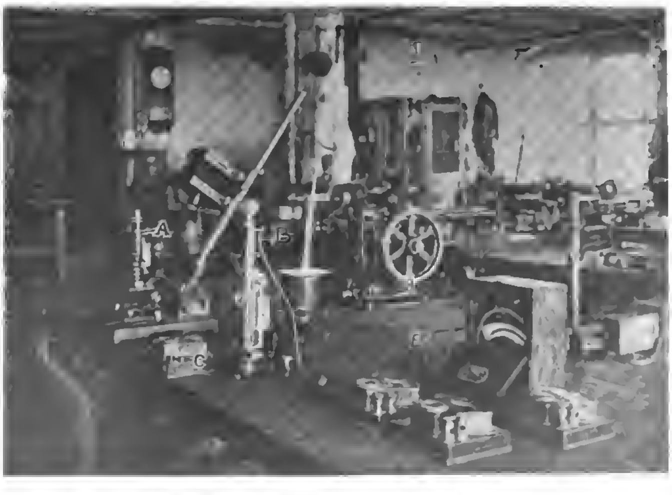

Fig. 17—A showing of instruments of precision required in the manufacture of high-grade automobiles

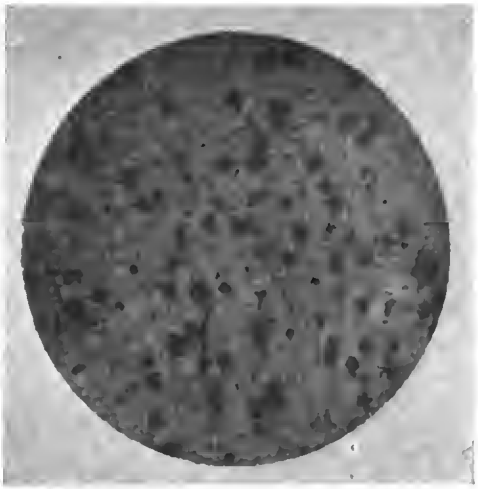

Fig. 18—Micro-photogram of malleable iron showing views at high magnification.

Testing machine offers a wide opportunity in the process of investigation. Considering the possible variations in materials and under different physical conditions, it affords a means for determining the tractive coefficient for the respective shapes.

Fig. 15 is a curve plotted to show the losses in watts under different loads considering differences in tires. There is a marvelous variation in the losses between the several tires. For illustration: The Palmer web tire on a 34-inch wheel under a load of 900 pounds shows a loss of 212 watts at 185 revolutions per minute; a cheap tire under a load of only 700 pounds shows a loss of 666 watts going at the same speed and considering the same diameter of tire; a special solid tire which was established as to its composition, after experimenting under a load of 700 pounds, on a 38-inch wheel showed a loss of only 238 watts, the speed being 185 revolutions per minute.

Referring to Fig. 16, an opportunity is afforded to observe the performance of solid tires as used in electrics, made under a wide range of loading in pounds on the wheel-bearing area, in square inches, depression in inches, and the product as given in terms of "product of bearing area and depression." This product has a certain value, in that it shows a diagonal line which is not parallel to the line of depression or that of the bearing area, but note that the lines representing bearing area and depression under changing loads are very nearly parallel. A long story is probably hidden away in the data obtainable on testing tires in this way. Some of it may be given in the future, when time and space are more favorable. For the present it will be enough to reflect the radius of possibilities by quoting from Mr. Newman:

"The process of testing a tire consists in delivering to the wheel which is equipped with the tire a certain amount of power at a given speed and measuring the amount of this power which the wheel and its tire delivers to the revolving drum.

"The difference between the power delivered to the tire and the power which the tire delivers to the drum is the power which is used up in internal or molecular friction within the tire. By varying such conditions as pressure on the tire, speed, torque transmitted, data can be obtained from which curves can be plotted showing the relation of internal tire friction to various external conditions.

"In the actual process of testing a tire, the wheel upon which it is mounted is withdrawn from contact with the drum and a Prony brake is mounted upon the shaft which supports the wheel and its tire. By means of this Prony brake the electric motor can be made to deliver the determined amount of power to the wheel shaft at the proper speed, and the input to the motor is then measured in amperes and volts by means of instruments inserted in the motor circuit."

INSTRUMENTS OF PRECISION FOR EXPLORATIONS

In a well-equipped laboratory, such as that of the Woods, the wide range of work which has to be done demands the use of a considerable equipment. Fig. 17 will give a fair idea of this:

(*A*) A metallurgical microscope with a camera.

(*B*) A "Shore Sclerescope" with which harness test are made.

(*C*) A mille-voltmeter connected to a pyrometer couple in electric furnace.

(*D*) A "Turner-Landgraf" alternate impact machine.

(*E*) A group of electrical measuring instruments.

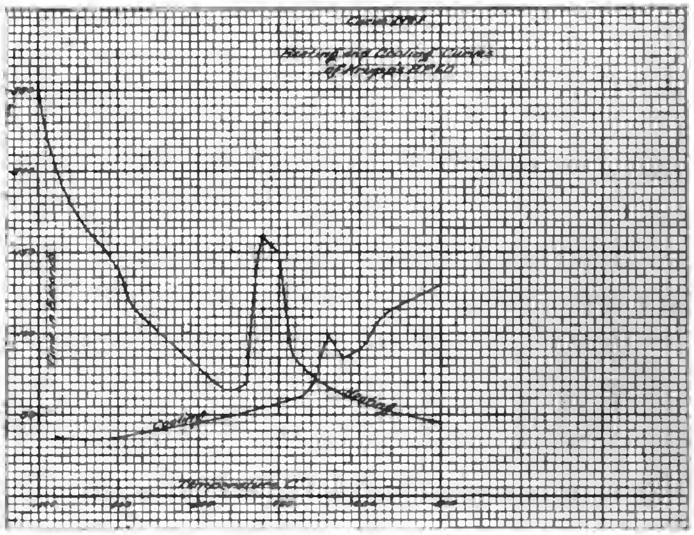

Fig. 19—Showing temperature performance of steel when it is being heated and when it cools off

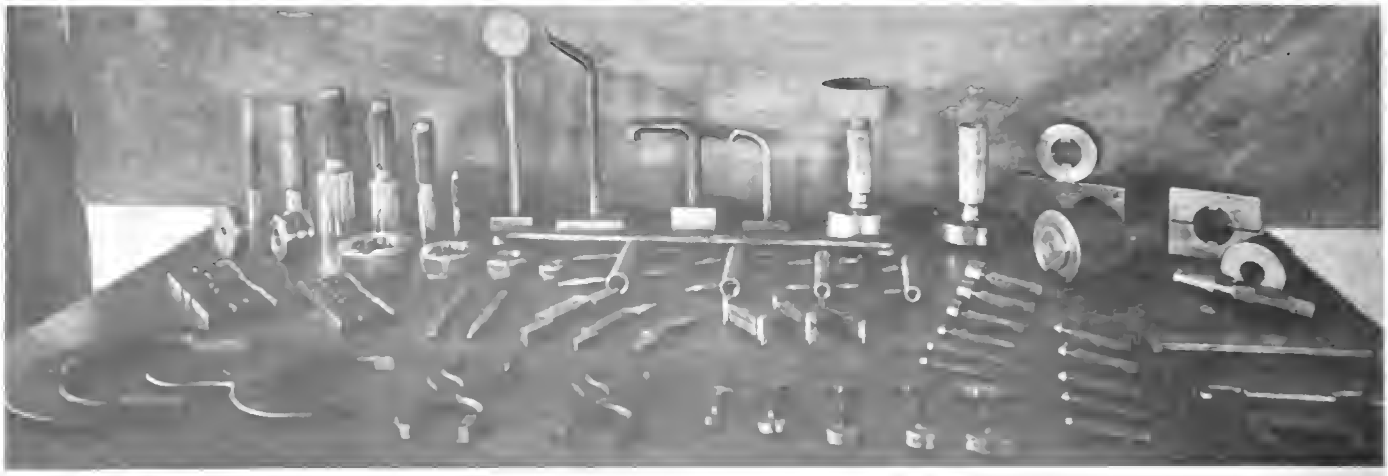

Fig. 20—A scattering of measuring instruments of the fixed order, as plug and ring gauges used by workmen in the shop

The metallurgical microscope permits the investigator to view specimens at from 100 to 1,200 diameters, thus bringing out the structural peculiarities. In steel in particular, it is possible to note if the metal is in the one or the other of the carbon states and the degrees of crystallization. When it is desired to make a record of a view through a microscope, the camera is brought into play. Fig. 18 is just such a view which was taken in connection with Mr. Newman's investigations in this case of malleable iron, the data governing the photo-microgram being as follows:

(*A*) Center of malleable casting, fully malleable.
(*B*) 2-3-inch projection.
(*C*) 1-inch eye piece.
(*D*) Etched 20 sec. 5 per cent nitric acid solution of alcohol.
(*E*) Seed process plates.

The time was when fabricators of steel had a monopoly of information in relation to the lack of qualities of their wares. This time has drifted into history. It did not take ten years of automobile building to bring out the fact that a kinetic machine such as an automobile demands qualities which do not reside in cast iron, yellow brass and Bessemer bars. Automobile engineers when they realized the condition which undoubtedly did exist on the marks of steel, then took time by the forelock, equipped their plants to make tests for themselves, and dictated quality where once it seemed to exist as a vague dream and nothing more.

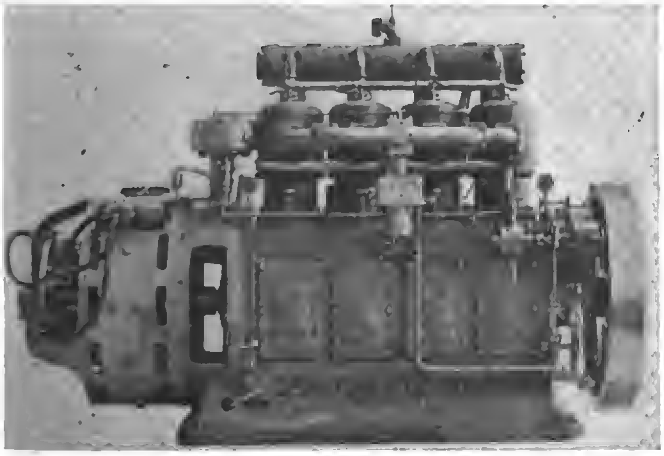

Fig. 21—Dynamo electric machine directly connected to a gasoline motor as used in charging batteries and other work

Fig. 19 is a curve which was plotted in the Woods laboratory, showing the temperatures of heating and cooling of Krupp chrome nickel steel, of the brand known as E. F. 600, as used in certain parts of great responsibility, as spindles, etc., in connection with Woods electrics. The chemical composition of this steel may be stated substantially as follows, with the understanding that there will be slight variations as between the respective heats:

Chromium	1.40
Nickel	4.40
Carbon	0.25
Silicon	0.20
Sulphur	0.013
Phosphorus	0.012
Manganese	0.36
Copper	0.006
Arsenic	0.007
Physical shape	bars.

The curve is interesting in that it shows the temperature at which a lag occurs, both in heating and cooling. This information, in itself, serves no useful purpose, but to the skilled manipulator it tells a story most necessary to know, if heat treatment work is to be done intelligently and if the results are to be on a predetermined basis. In the well-equipped plant, then, as compared with haphazard establishments, things go by direction, and enforced co-operation is the order of the day.

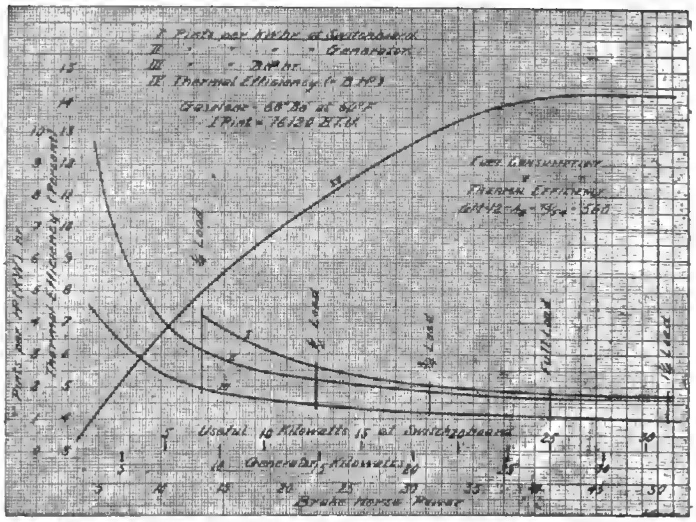

Fig. 22—Characteristic of dynamo performance, presenting evidences of great value of graphic methods

FIXED GAUGES ADVANTAGEOUS IN THE SHOP

The system of go-gauges as manufactured by Brown & Sharp and other makers of instruments of precision are probably quite well understood in a general way, and yet it remained for establishments like the Cadillac Motor Car Company, Detroit, to bring the system to the highest state of perfection, producing exact work, invariably without excessive augmenting cost.

By way of illustration, in the Cadillac plant this system of go-gauges is utilized in a secondary way—that is to say, a system of master plug and ring gauges are kept in the tool room, they being precise as to dimensions and sufficient in range to cover every measurement required to be made in connection with the building of Cadillac automobiles. In the shop, each workman is provided with plug and ring gauges which are precisely sized to measure the very operations the workman is required to perform, and all that he has to know is that the gauge will or will not go. A plug gauge in this system takes advantage of the

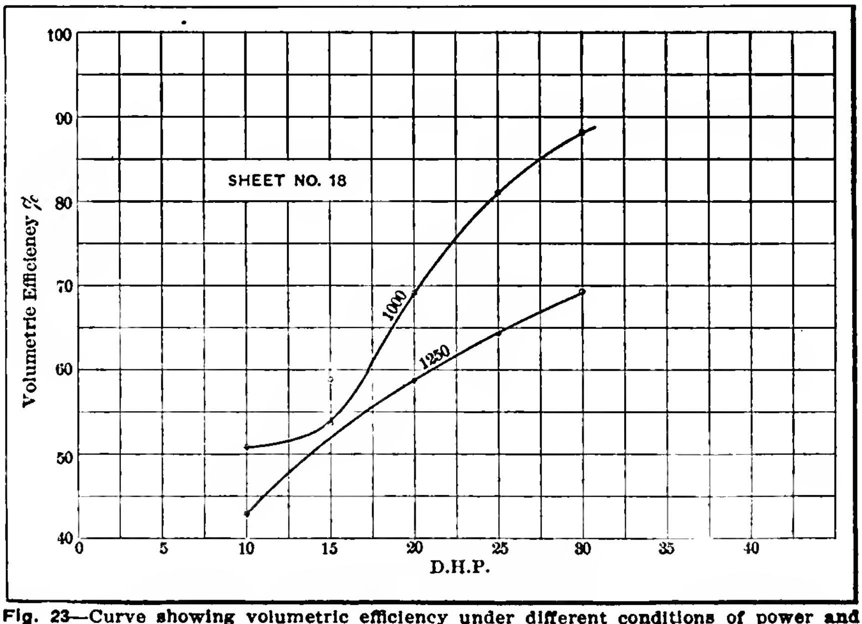

Fig. 23—Curve showing volumetric efficiency under different conditions of power and speed of a Pierce motor

allowable limits of variation in that one end of the gauge is just a little too big for the right-sized hole, so that it will not go, and the other end of the gauge is as much smaller as the limit of tolerance fixed for the work indicated. If the work is ground to the right size the gauge will go. If the work is a shaft or other part to be measured over its diameter, ring go-gauges supplant plug go-gauges. The accuracy thus arrived at in the hands of men of sufficient caliber is made possible by the go-gauges, and the gauges of course are as accurate as the company cares to have them. Interchangeability does not demand a neat fit of parts, but it does indicate narrow limits of tolerance. Fig. 20 represents an assortment of gauges of this character, they being but a few of the many in common use.

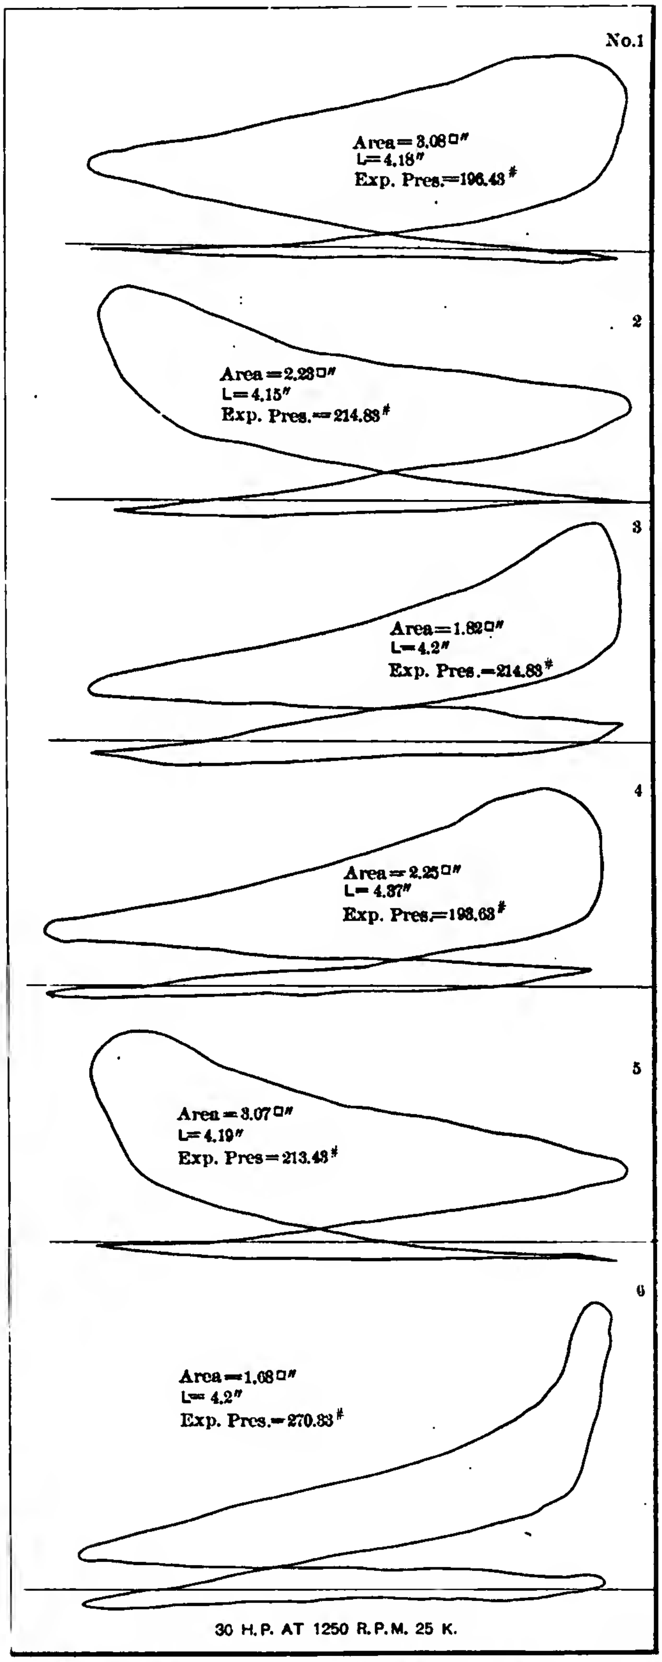

Fig. 25—Manograph card from the six cylinders of a Pierce taken at 1,250 revolutions per minute.

Disjointed facts in the abstract rarely ever afford insight into

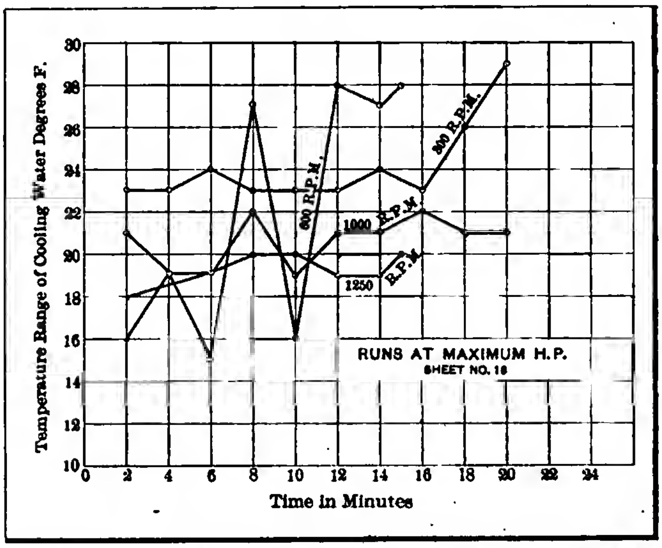

Fig. 24—Chart plotted to bring out performance of cooling water under different conditions of power and speed

the workings of an intricate situation sufficient to satisfy the ends to be met. When all the facts which are known are presented in graphic form they take on the characteristics of a bird's-eye view and the unknown quantities may then be estimated within reasonable limits of certainty.

In order to better understand the value of a graphic presentation Fig. 21 is offered. This represents a dynamo electric machine, directly connected to a gasoline motor as manufactured by the General Electric Company at the Schenectady plant. It is of the same type used for lighting, the charging of storage batteries and kindred work.

The dynamo has an output of 25 kilowatts, as normally rated. It may be overloaded to the point known as 1 1-4 load for a specific period of time. When the dynamo is delivering its full load the gasoline motor must deliver nearly 42 actual horsepower, and, as the illustration indicates, the motor has all the ear marks of automobile motors, with the exception, of course, that the base is shaped to stand on a foundation rather than to be cradled in a chassis frame as in automobile work.

Illustrating the utility of the graphic method of arriving at and recording engineering data, Fig. 22 is afforded, it being a presentation of the characteristics of the 25-kilowatt generator set as shown in Fig. 21. In making the test the engineer in charge used gasoline, the specific gravity of which was 68 degrees Baumé, at 60 degrees Fahrenheit, and it was found by test that one pint of the gasoline contained 16,120 British thermal units of heat (B. T. U.).

The columns of figures to the left on the chart fix the valves of abscissa, first in pints per horsepower hour of the gasoline used; second, in terms of thermal efficiency (per cent). The values of ordinates, reading from the bottom up, are first, in terms of brake horsepower required to drive the generator under the several conditions of load; second, the output of the generator in kilowatts, measured at the terminals of the same, and third, the energy actually delivered at the switchboard as measured in kilowatts.

With this chart available, it is possible to see at a glance the relative performance of the generator under varying conditions. For illustration, referring to curve IV and at 3-4 load, the thermal efficiency is 13 per cent (slightly under) which is found by following up the ordinate representing 3-4 load to the point of intersection of the curve IV with the abscissa which has the value of 12.9 (very nearly 13 per cent). This curve shows that the thermal efficiency increases as the load becoming a maximum at a point just beyond full load, and holding stationary thereafter. The thermal efficiency is of course very low for everything under 1-4 load, it being about 7.8 per cent at that point. This value 7.8 for the thermal efficiency at 1-4 load is relatively very good, it being about the maximum thermal efficiency for the average high-speed slide-valve steam engine. Granting this, it follows that the thermal efficiency in internal combustion motors at anything above 1-4 load increase very rapidly above the average thermal efficiency under conditions of average steam practice.

There is one other point of importance which is clearly shown in this graphic presentation. It relates to the gasoline consumption under the varying conditions of load. Considering the power of the gasoline motor in brake horsepower, and utilizing curve III, it will be observed that 1.1 pints of gasoline will serve for one horsepower hour when the motor is running at full load of the generator. This gasoline consumption increases by gradual increments up to 1.9 pints of gasoline per horsepower hour, when the power delivered is that required at 1-4 load of the generator. The thermal efficiency falls away with decreasing load because the gasoline thus increases. This chart, while it is primarily related to this generator set, reflects conditions which will be found in gasoline motors in general, and, to a certain extent, as they are used in automobile practice, with the exception, however, that the better conditions, which obtain in automobile work, will reflect a little more favorably and the thermal efficiency will be on a little higher plane.

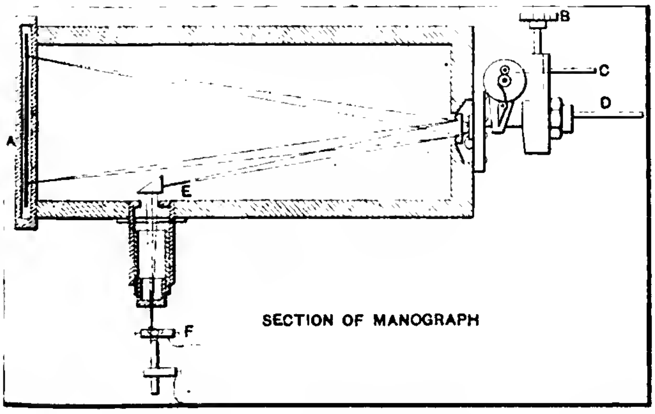

Fig. 27—Section of the manograph used in the testing of the Pierce motor under direction of Prof. Rola C. Carpenter

Unfortunately, the volumetric efficiency is not constant under all conditions of load and speed, when reference is had to internal combustion motors. In automobile work in particular, both the load and the speed vary over the broadest ranges. This volumetric efficiency is graphically represented in Fig. 23, which was taken from the Pierce series of tests, and it presents the situation very aptly. The volumetric efficiency decreases with increasing speed, due to the decreased time which is afforded for the incoming mixture, and by volumetric efficiency measurements it is possible to ascertain when the suction pressure crosses the atmospheric line. Under different conditions of power when the motor is running at 1,000 and 1,250 revolutions per minute respectively, the efficiency reaches its maximum of about 88 per cent in this particular motor at 30 horsepower for the speed given.

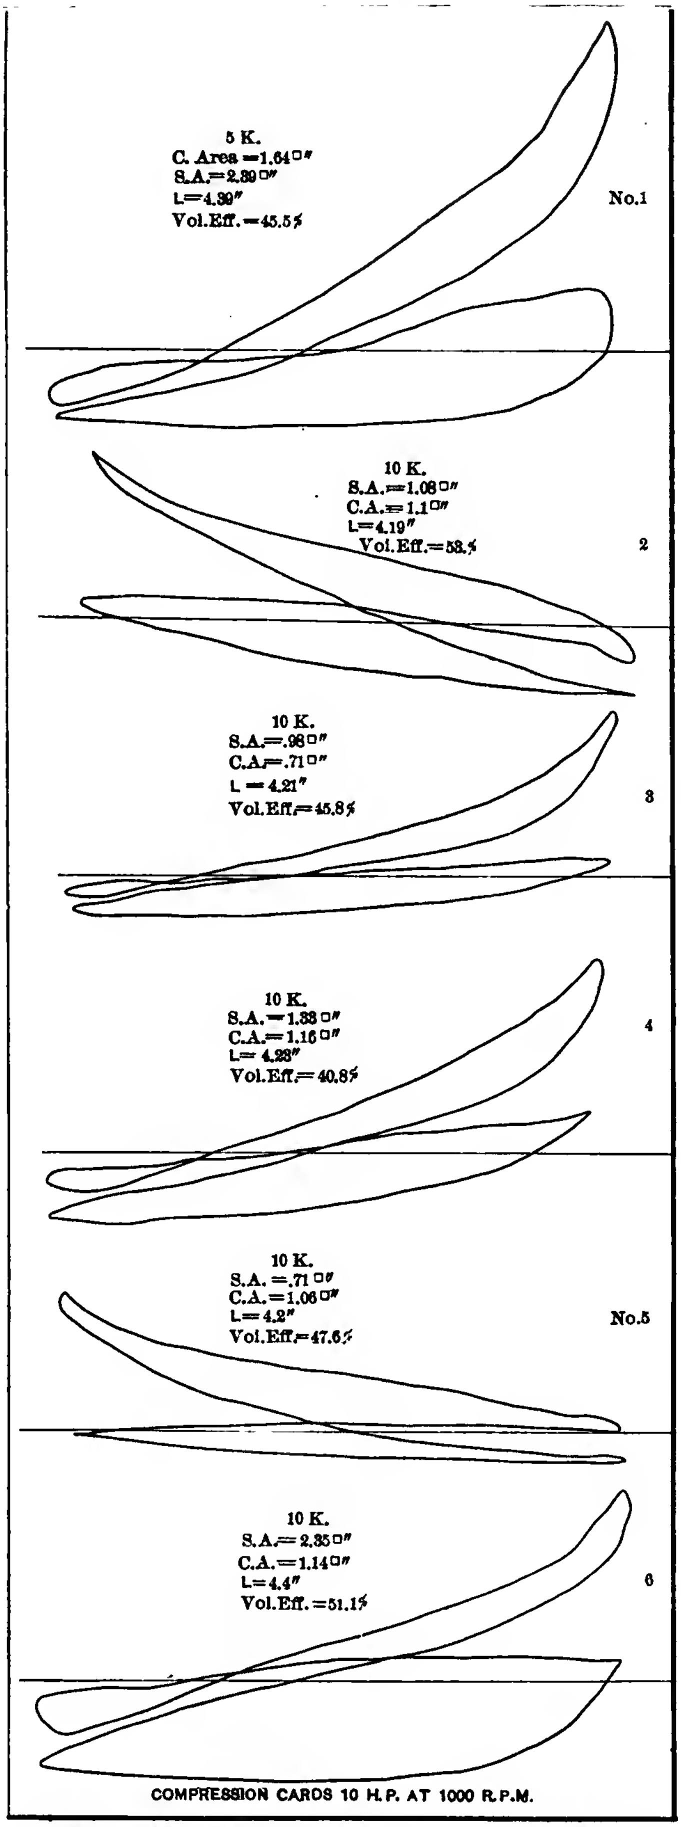

Fig. 26—Monograph cards from the six cylinders of a Pierce motor running at 1,000 revolutions per minute

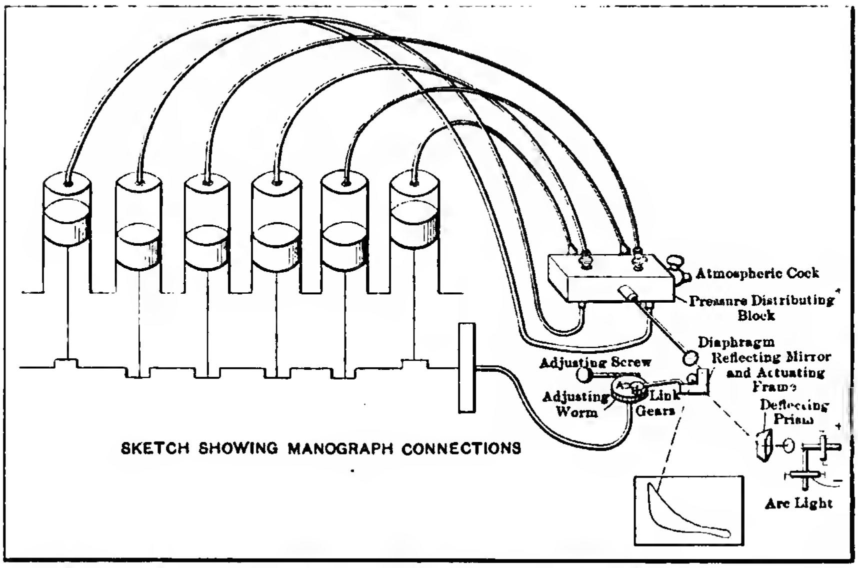

Fig. 28—Scheme of connecting up the manograph as it was used in the conduct of these tests

Influence of Temperature of Cooling Water—As a further illustration of the advantages to be derived from graphic methods reference is here made to Fig. 24, in which abscissa are in terms of temperature range of cooling water in degrees Fahrenheit; ordinates are in terms of time and minutes, and the motor, which was a "six," was run under conditions of maximum horsepower at several speeds from 600 to 1,250 revolutions per minute, inclusive. The temperature changed rapidly and violently when the motor was run at the low speed, which was 600 revolutions per minute. This goes to show that motors are prone to heat up, perhaps excessively, when the load is maximum for the minimum speed. The same characteristic is noted at a speed of 800 revolutions per minute, excepting that the changes are not so sudden. Nevertheless the temperature of cooling water increased persistently after a run of 16 minutes, whereas at 1,000 revolutions per minute the temperature ceased to increase after 18 minutes.

Autoists before acquiring a fair measure of experience frequently have what is termed "cooling trouble." It rather looks to the author as if it is in the nature of "heating trouble." This trouble comes primarily for reasons which are reflected in the chart Fig. 24, but they are accentuated if the motor is run on a retarded spark. Under the circumstances, in view of the information afforded, it would seem to be a good practice to avoid retarding the spark in the process of operating the motor at the low speed. Altering the richness of the mixture and the quantity thereof (putting it up to the carburetor)' would favorably influence this heating trouble.

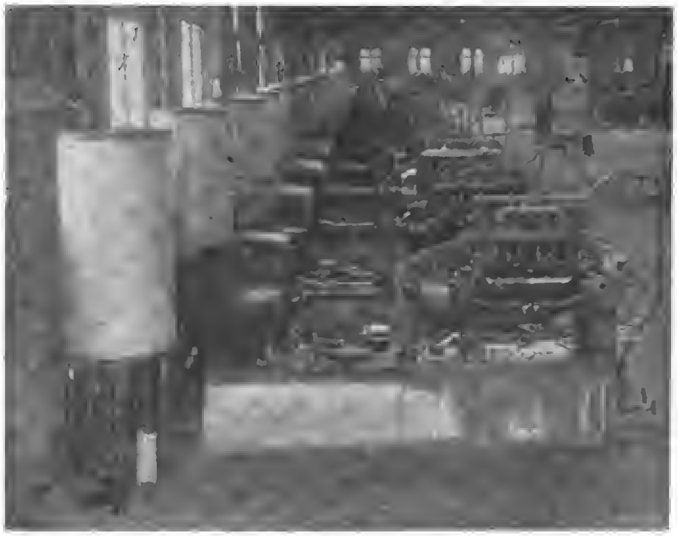

Fig. 30—Row of testing blocks as used at the Rambler plant for testing motors

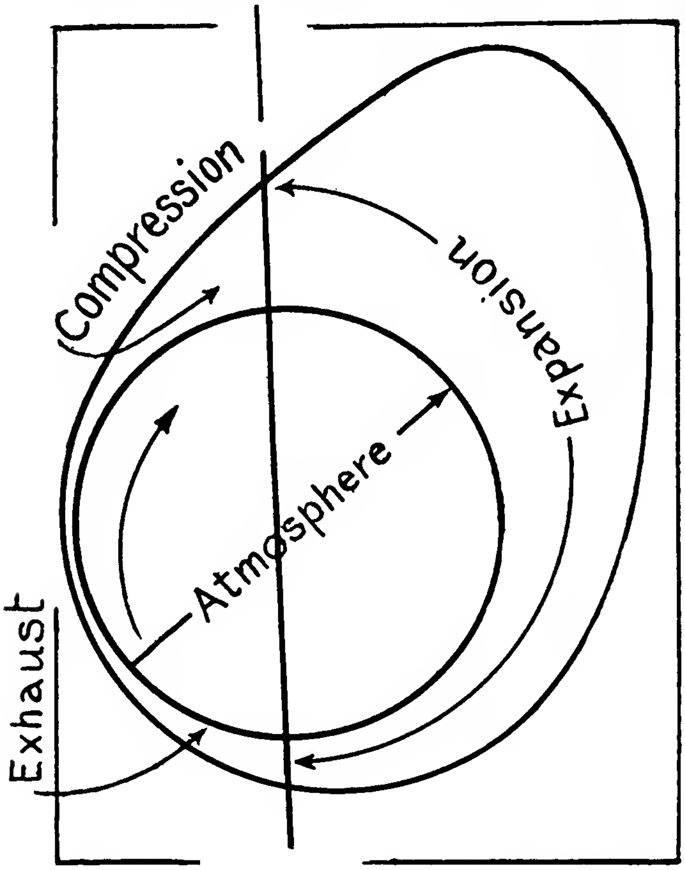

Fig. 29—Card from Purdy manograph, as taken at the Rambler plant by the inventor

UTILITY OF THE MANOGRAPH CONSIDERED

On account of the very high speed at which automobile motors operate, inertia, lost motion and other imperfections of indicators in general, renders them wholly unfit for use in determining the gas performance in the cylinders. The manograph, as an instrument, was contrived with the idea of overcoming these troubles, and it possesses certain virtues, among which is practically no inertia—this because of the utilization of photographic principles, on the theory that a beam of light is substantially free from inertia.

The cards taken by means of the manograph, as it is ordinarily used, look very much like the cards which are taken with a steam indicator. Fig. 25 shows the set of cards which were taken for the Pierce Company, one from each of the six cylinders of a Pierce motor, when the same was delivering 30 horsepower at 1,250 revolutions per minute. The information given on the cards is sufficient to make further discussion unnecessary at this time, save that it will be of advantage to have a set of compression cards from the same motor. This set is given in Fig. 26. They were taken when the motor was operating at 1,000 revolutions per minute delivering 30 horsepower.

The manograph used in this case was the Hospitalier-Carpentier, and the work was done under the direction of Prof. Rola C. Carpenter by graduates of Sibley College, Cornell. The section of the manograph shown in Fig. 27 and the method of connecting up is given in Fig. 28 with sufficient descriptive matter appended to satisfy the present situation.

Purdy Polar Manograph Has Advantages—In view of the importance of the subject, mention will be made of the Polar type of manograph now used in the Rambler plant of Thos. B. Jeffrey & Company, Kenosha, as invented by Frederick Purdy, Chief of the Rambler laboratory. This manograph produces a card as shown in Fig. 29, in which the beam of light rotates and presents a perfect circle at the atmospheric pressure, expanding as the pressure increases. In determining the pumping losses from this card all areas to the left of the center line represent losses, while the area of the expansion zone to the right represents useful work. It takes a little studying to make one familiar with this type of card, but it is entirely free from inertia and has other advantages which the author hopes to bring out at an early date.

A. L. A. M. LABORATORY WORK

In order to bring about a standardized set of conditions, the Association of Licensed Automobile Builders maintained what was designated as the Mechanical Branch, which was under the direction of a committee made up of chief engineers from some of the companies, and, having established a laboratory at a convenient point, investigated materials and conditions involved at length for the common good. It will be impossible to review the workings of the Mechanical Branch further than to briefly summarize a part of the result, sufficiently perhaps, to indicate the high character of the undertaking, and to enable purchasers of automobiles to appreciate at least a part of the reason why so much progress has been made in so short a time.

Specifications for Gas Engine Lubricants—In view of the importance of good lubrication, especially in cylinders of motors, investigations were made and the report rendered was as follows:

"Oil for this purpose must be a pure mineral oil, no addition or adulterant of any kind being permitted.

The following characteristics are desired:

Flash point (as determined in open cup) should not be less than 400 degrees Fahrenheit, and the fire test should not be less than 450 degrees Fahrenheit. Viscosity as measured at 100 degrees Fahrenheit, using a Saybolt Viscosimeter, should read not over 300 seconds. At other temperatures the viscosity should be as follows:

At 210 degrees Fahrenheit (Saybolt) 40 to 50 seconds.

At 210 degrees Fahrenheit (Tagliabau) 60 to 75 seconds.

Specific gravity should indicate between 30 and 32 degrees Baumé.

Residue on evaporation not over 1 per cent.

According to the recommendation the flash point should be the lowest degree at which the vapor ignites and goes out.

The fire test should be the lowest degree of which the vapor ignites and continues to burn.

The specific gravity may be determined by special hydrometers, or better, by means of a Westphal balance.

Residuum on Evaporation—This test is of a special nature; in a retort (No. 16,384 Bausch & Lomb, or No. 3,873 Eimer & Amend) is placed between 40 and 50 grammes of oil carefully weighed. This retort is then put over the naked flame of a Bunsen burner and heated slowly to the boiling point, continuing the heat until all the liquid portion of the oil has passed over and out of the retort. The heating is then further continued by passing the flame over the entire surface of the retort in such a manner as to drive off everything possible from the body and neck of the retort which can be driven off at an incipient red heat. This is a temperature at which the glass in the retort begins to soften.

A coke-like residuum will be found in the retort. When the retort is cooled, this residuum should be weighed and the percentage of residuum, as compared with the original weight of the oil, may then be determined.

Only the best makes of retort will answer for this test, and for reliable work it should be made of Jena glass. Even with this quality of retort breakages are frequent, and, as a matter of fact, the test must be conducted with the greatest care.

ROBERT W. HUNT & CO

REPORT OF PHYSICAL TESTS

Exhibit "C"

CHICAGO

A25 J27

6/10/08.

Fig. 32—Method of reporting investigations of steel as made by the Hunt laboratory

The Mechanical Branch of the A. L. A. M. fully settled a great many of the lubricating controversies for the manufacturers of automobiles, and eliminated speculation in so far as they are concerned. In the same way, the Mechanical Branch took up with the questions of steel, brass, bronze, and babbitt metals, fixing the limits within which it is safe to operate, considering the materials available or to be had by special heat.

A.L.A.M. SPECIFICATIONS NO. 3 FOR NICKEL STEEL

Nickel, 3.00.
Carbon, 0.20-0.28.
Silicon.
Sulphur, 0.04.
Phosphorus, 0.04.
Manganese, 0.60-0.90.

PHYSICAL PROPERTIES REQUIRED

Tensile strength, 85,000 pounds per square inch.
Elastic limit, 55,000 pounds per square inch.
Elongation, 25 per cent. in 2 inches.
Reduction of area, 50 per cent.
Condition, annealed.

PHYSICAL PROPERTIES AFTER HEAT TREATING

Tensile strength, 100,000 pounds per square inch.
Elastic limit, 70,000 pounds per square inch.
Elongation, 20 per cent. in 2 inches.
Reduction of area, 50 per cent.

Sept. 1, 1909.

Note: The front areas, as given, do not tell the whole story. In order to be able to ascertain why the respective motors perform satisfactorily even though the front areas are not the same, it is necessary to investigate the motors, and determine the flame-swept surfaces, efficiencies, and depth of radiators, as well as other matters. This table tells of one phase of the effort to evolve quality, the other phases having been taken up in regular order.

Electrics Extending Scope of Usefulness

By Thos J Fay

HISTORY as it relates to electric vehicles presents a long series of efforts undertaken in the process of bringing the storage battery up to its present state of efficiency. The electrical equipment in general was substantially protected, even before the electric vehicle became a serious undertaking, but the battery situation retarded progress for a number of years, not so much due to inherent lack of ability of the storage battery as

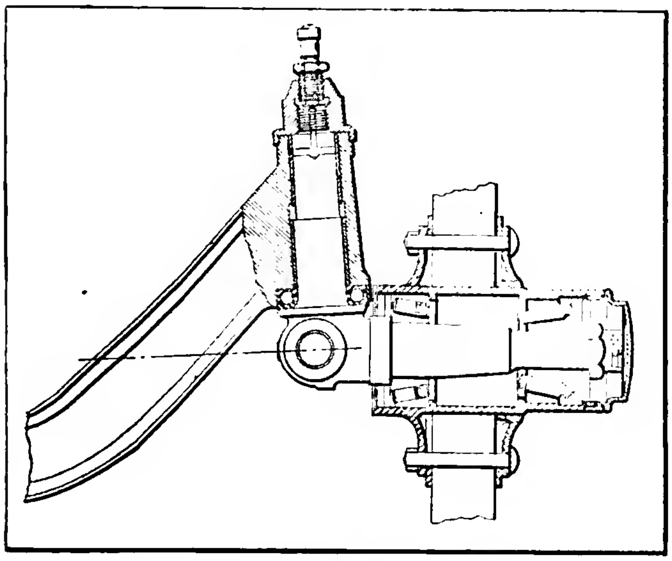

Fig. 1—Lemoine type of steering knuckle with Timken roller bearings and a ball thrust

a type, but to lack of training of the men who were required to handle an electrochemical equipment, they not being possessors of sufficient knowledge of this highly technical character.

ELECTRIC VEHICLES MECHANICALLY CONSIDERED

In a general way, the running gear of an electric vehicle differs but slightly from the same class of gear, as it obtains in gasoline automobile tactics. The wheelbase is generally shorter in the electric vehicle, the center of gravity is probably a little lower, and the chassis frame is frequently dispensed with, the body serving adequately for the intended purpose. This being of wood has the virtue of resisting the fumes of acid. The acid fumes come, of course, from the battery during the charging period, owing to the presence of sulphuric acid in the electrolyte, the specific gravity of which is about 25 degrees Baumé.

Barring the structural features in electric vehicles, which are brought about to considerations as above, the whole mechanical situation is one which can be treated in a rational way, and in the cars which will be on exhibition they present normal features, differing in a schematic way, so that they may be subdivided in classes as follows:

(A) Side chain drive types as exemplified in the Woods electric vehicle.

(B) Worm drive, of which the Babcock is a fine example.

(C) Shaft drive as presented in the Baker.

(D) Silent chain drive as exemplified in the Studebaker, Detroit Electric, Waverley, Rausch & Lang, Columbia, Bailey and others.

Next to the electrical features which influence the mechanical structure in these vehicles, it is very likely that for the rest, modern drop forgings, steel pressings and anti-friction bearings, are representative of the very best practice. The front axles are pretty generally of the eye section, made in one piece, and while Lemoine, Elliott and the other standard types of knuckles are used, they more often than not have a ball thrust bearing to carry the load. The wheels roll on annular types of bearings in some cases, Timken roller bearings in others, and cup and cone bearings to some extent.

Rear axles are fairly well divided between side chain drives and live types. Taking the side chain drives, and using the Woods type as an illustration, the point will be made that the sprocket chains are rendered noiseless by using the best class of chains over accurately cut sprockets, and with means for maintaining precision of alignment and distance. Referring to the live types of axles, numerous of the examples are equipped with full floating types of jack shafts, and the driving jaws are especially large and particularly well fitted. In this class of work, in view of the desire of mileage without heavy drafts on the battery, it is this precision of mechanical fit and well executed detail at every point which indicates the way to prime success.

SPRING SUSPENSION AND RIDING QUALITIES

In view of the weight of battery which has to be carried, frequently reaching at least 2000 pounds, referring of course to the most pretentious types of electric vehicles, the spring suspension must be most carefully thought out, and the character to be determined of material and workmanship incorporated in the springs taxes the ingenuity of the most expert spring makers. In this type of car platform types of springs are much in vogue, they have the requisite characteristics, and the further effort is by way of utilizing a sufficient mass of suitable material. It is now a well-established principle in spring making that quality of material is not the sole criterion. There must be a certain quantity of material used, the mass of which must relate to the foot pounds of energy represented in the body oscillations. The spring makers who deal with this problem are fully informed as to the facts, and, from results attained, it seems to be a fair conclusion that they have taken advantage of every opportunity.

WIRING CONTROL AND OTHER FEATURES

With a view of insuring a minimum of losses when the draft on the battery is maximum, the sizes of wire used are generally such that the drop in volts will be well within 2 per cent. when the current in amperes is equal to three times the normal draft. The wire used is of the class known as "flexible cable" made from pure lake copper, insulated to a good thickness by acid re-

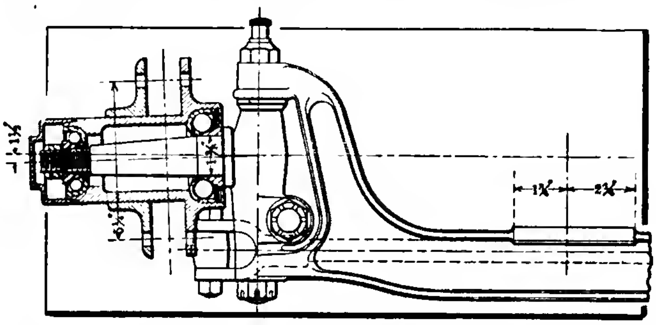

Fig. 2—Elliott type of steering knuckle with eye section axle and cup and cone ball bearings

sisting rubber compound. Cotton braided insulation is not used in view of the effect of acid upon it. The wires are run in wooden casings, or on porcelain insulators, and the preference is for a perfectly accessible position, in order that trouble, if it should creep in, may be quickly found and eliminated.

Controllers are frequently of the drum type, designed for continuous torque work, and five speeds ahead with one reverse seems to be the general practice. Electric vehicles in pleasure service are provided with interlocking devices so contrived that

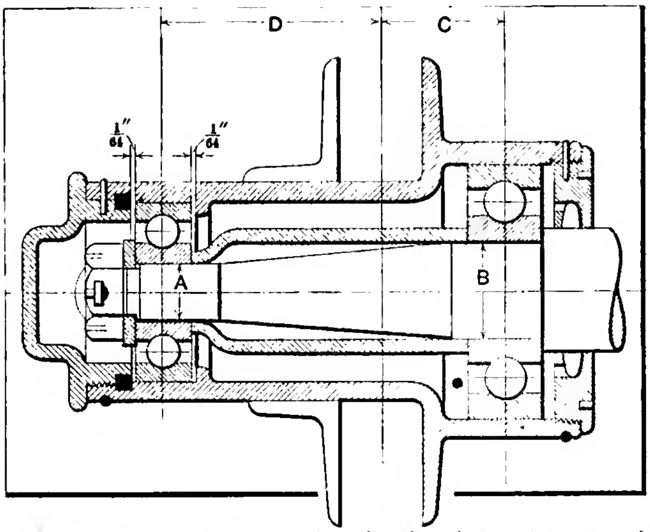

Fig. 3—Annular type of ball bearings for side chain drive rear axle

the operator (if absent minded) is protected as against wrong moves, the idea being to make it impossible to start an electric vehicle excepting gradually, and under precise conditions, which is a matter involving progression, starting the car slowly and gradually working up to the highest attainable speed.

Brakes are mostly mechanical, of great competence and duplicated, thus affording the ordinary service brakes for regularly operating and emergency brakes against an occasion. To some extent electric brakes are utilized also.

STORAGE BATTERIES SIMMERED DOWN

In 1881 M. Camille Faure in France and Charles F. Brush in America, working independently, but along similar lines, patented (Faure in France and Brush in America) methods of hastening formation of active materials on the grids of plates used in lead storage batteries. Since then progress has been slow but sure, knowledge has amplified and makers of storage batteries, against great resistance, due to prejudice born of lack of electrochemical knowledge, have persistently fought. To-day, however, storage batteries are as stable as banks and electric vehicles depend absolutely upon them for success.

The history of the storage battery dates back of the efforts of Brush and Faure, in fact, back to many early investigators, among which the following were the more prominent:

HISTORY OF STORAGE BATTERY EFFORTS

Year. Discovery.

1800—Volta discovered the galvanic battery.

1901—Gautherot discovered that if platinum or silver electrodes were connected together after they were subjected to an electrical charge, a discharge would follow.

1803—Ritter made the same discovery, substituting gold wire for platinum or silver. He superimposed plates of gold, separating them by means of discs of cloth, moistened the couple with ammonia water and observed that a secondary current of good strength and efficiency followed each charge (electric) of the couple.

1837—Schoenbein discovered that peroxide of lead was a medium of great efficiency in storage battery work.

1837—Volta, Davy, Marianini, were successful in adding much to the store of knowledge.

1842—Grove constructed his famous gas battery and he demonstrated that the voltage obtained was due to electrolytic action, liberating oxygen and hydrogen, the electrolyte being acidulated water, using sulphuric acid for the purpose. Grove, by the way, prior to 1842, came forward with the statement that metallic grids, coated with oxide, were better than metallic grids for the purpose, and Wheatstone, as well as Siemens (prior to 1842), found that peroxide of lead was the most efficient for the purpose.

Michael Faraday, about this time, added to the store of knowledge, he having discovered that after electrolyzing a solution of lead acetate, peroxide was produced in the positive plates. Niblett stated that Wheatstone, Niaudet and de la Rue were cognizant of the powerful depolarizing action of peroxide at that time, but it was not taken advantage of then.

1860—M. Gaston Planté constructed his well-known secondary battery, in which sheets of pure rolled lead were separated from each other, by means of felt, and they were then rolled up into a coil, submerged in sulphuric acid electrolyte, and charged; the first practical storage battery was the result. The title to Planté's distinction was somewhat clouded, due to the claim made by M. Duerlir, that Sinsteden took advantage of the secondary action of lead in a bath of sulphuric acid in 1854.

1879—Metzger did away with the long snd costly forming process by applying active materials to the metallic grid, thus aborting the necessity of growing active material out of the metallic lead of the grids.

1881—M. Camille Faure, in France, precured letters patent on a process of mechanically applying the active materials to the grids.

Charles F. Brush, in America, took out letters patent on the mechanical process of mechanically applying the active material to the metallic grids.

In an action at law, in the United States, the Court ruled that to Charles F. Brush belonged the honor of the invention.

History, as it is written in France, dissents with the Court which ruled in favor of Brush.

THE THIRTY YEARS' WAR

From 1880 down to the present time represents the period of development, as it were, of the storage battery, and during this time so many patents were taken out by such a large army of inventors that to record them would demand more space than would be available in a Show Number of The Automobile. This period of 30 years represented a war of mind over matter, involving millions of dollars, a myriad of failures and final success.

Strange to relate, the storage battery of to-day, clothed in the ermine of success, is but the storage battery of 1881, carefully made and conforming to the tangle of laws; laws that when offended, as they formerly were, made known their displeasure, and failure was the reward of the offenders.

Distinctions To be Drawn—The Planté type of battery, which was the product of 1860, is one in which the active material is formed out of the grids which compose the elements of the cells of battery; whereas, the Faure type is the one which takes advantage of the mechanical application of the active material.

Earlier methods, involving both generic types of battery, were long ago discarded in favor of more efficient ways of accomplishing the desired results. For illustration: In the Planté type

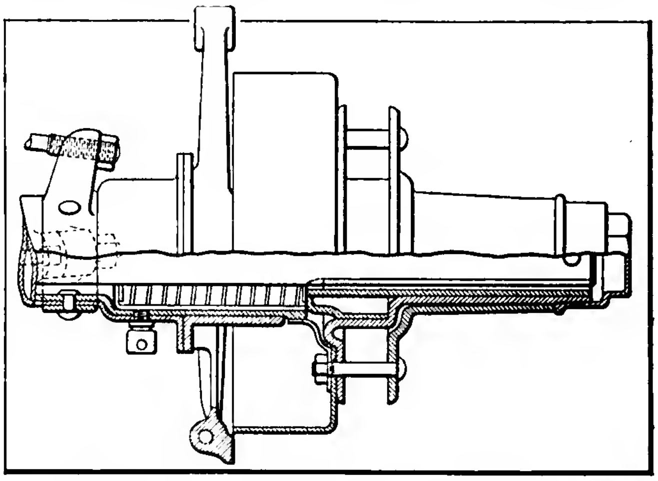

Fig. 4—Hyatt type of roller bearings as used in live rear axles

of battery, as it is made to-day, the grids are first "spun," an idea introduced by Madden and Chamberlain in 1896 (Letters Patent U. S., No. 572,363) and one now in vogue, especially for negative plates in Gould storage batteries. The spinning process is conducted in an especially devised machine, in which the sheets of pure rolled lead are placed and deep grooves are made by means of rotary knives, placed in gangs on a mandrel, so arranged that the original surface of the plate in each instance is increased enormously. The spun plates are placed (between dummies) in a forming electrolyte, and when a charging current is passed through the plates they quickly grow a deep coat of active material which completely fills the furrows.

In the Faure types of plates instead of subjecting them to a spinning process they are cast under pressure, using an alloy of lead and antimony to give strength. Then a lattice work formation of the moulds brings out the grids in shape to enable them to be filled with salts of lead formed into a paste. The active material is then readily formed and the ampere hour capacity of the batteries so made is found to be great in comparison.

In the earlier attempts to make batteries in this way, owing to lack of knowledge of the phenomena which transpired in the charging and discharging cycles, the materials failed to stay in place sufficiently long to satisfy the commercial needs. Then improvements made were mostly in this direction, it being the case that they gradually mounted to a high plane, and to-day as it can be safely said, in view of the rapid growth of electric vehicle enterprises, that the storage battery is stable, efficient and so commercially capable to meet all reasonable requirements.

WATT OUTPUT AND LIFE RELATED

Since a lead cell of battery has a potential difference of about two volts (between 1.8 and 2.2 volts, which is the discharging range), it is necessary to employ enough cells in series to make up the voltage for which the motor is wound, limiting the number of cells in series, however, to that number which, when charged in series, will permit of charging on the circuit available for the purpose.

When batteries are being charged there are times when the voltage should be on a basis of 2.6 volts per cell and with 44 cells in series (not counting "drop" in the wiring system) the charging voltage must equal 114.4, which, including probable "drop," brings the circuit voltage up to 120 as a low figure, it being true, as a rule, that the "drop," which may be quite noticeable in wiring, switches and connections, will equal more than five volts.

With 44 cells of battery in series, considering the average voltage on discharge as, say, 2 volts, the motor would be wound for, say, 90 volts, and the fields, which would be series wound, would take care of all voltage variations, since the exciting current would be the same as that entering the armature. In some cases, when the voltage of the charging circuit is down to 115, 40 cells of battery are used, and the motor is then wound for 80 volts.

When the battery, as respects the number of cells used, is not matched up with the circuit with which it will be connected for purposes of charging, one of two things must happen: (A) If the charging voltage is not high enough the battery will be starved, sulphation will take place and the life of the battery, also its output, will fall below the obtainable level. (B) If the charging voltage is excessive the battery will be destroyed, unless a resistance is inserted in series with the battery sufficient to cause a drop equal to the excess of voltage.

The right number of cells to use then is that number which can be correctly charged, considering the circuit available, and the motor for an electric vehicle must be wound for the mean voltage of the battery. These are matters of the gravest importance and probably the details which, being well cared for, have brought battery life, hence vehicle satisfaction, up to a very high level in the estimation of users.

With these matters properly attended to, it is possible to intelligently discuss the questions of watt output of batteries and so learn how it is that life and watt output are entwined.

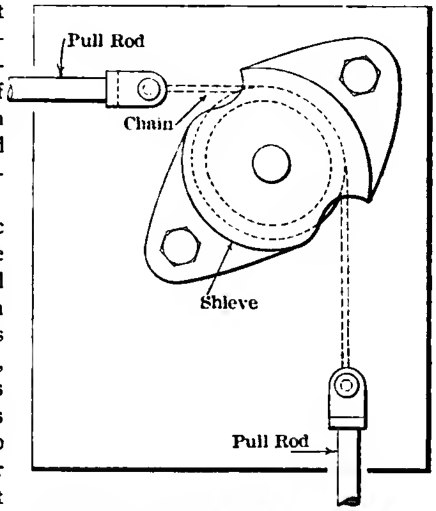

Fig. 5—Flexible cable and shleve as used with brake cables to make turns

The average electric vehicle of the pleasure type will run on a hard level road at maximum speed at, say 80 volts and 20 amperes, and, since volts by amperes equal watts, it follows that 80 × 20 = 1,600 watts, which, per hour, represents watt hours.

If the battery used under these conditions will furnish the necessary current in amperes, say, four hours, the watt output will then be (taking an average) 6,400, and if the battery weighs 400 pounds the watt output of the same will be on a basis of 16 watt-hours per pound of battery.

The watt output of a battery depends upon the conditions as follows:

(A) Surface of positive plates, assuming the negative plates are equal to the requirement, which is generally true, and in the better class of batteries, negative plate capacity is in considerable excess, thus affording long life.

(B) Weight of active material in positive plates, assuming the same to be capable of conversion; or, better yet, counting that portion of the positive active material which is converted during charge and subsequent discharge.

RATE OF DISCHARGE AND OUTPUT OF A BATTERY

Discharge Rate	Ampere Hours Output
In 10 hours	100
In 8 hours	98
In 6 hours	93
In 4 hours	82.5
In 3 hours	75
In 2 hours	65
In 1 hour	50

AN EDITORIAL ANNOUNCEMENT

After four years of service as managing editor of "The Automobile" there comes a severance of pleasant relations with The Class Journal Company, in order that I may assume new duties in a field that once before strongly appealed to me. From the national secretaryship of the American Automobile Association in 1906, I moved to the editorship which I am now relinquishing to become again identified with the A.A.A. as chairman of its Executive Committee and publisher of its official monthly magazine. If the readers of "The Automobile" share the expressed belief of The Class Journal Company that my efforts have contributed some additional interest to its pages, even in part, then I shall consider that the years spent were well employed. A. G. BATCHELDER.

OPTIMISM MARKS PALACE SHOW

Apparent from blocks away, all through the three or more floors of the Grand Central Palace, and particularly noticeable among the salesmen and agents, is the cheerful optimism of this year's A. M. C. M. A. Show, holding forth during the present week in New York City. Not alone are the public pleased with the fine, brave showing which the cars themselves have made, but their sponsors are jubilant, the factory representatives elated with the business transacted, and there are none worried, except possibly some isolated sales agent whose allowance of cars may be cut down.

As is usual, the decorations and arrangement of the building and exhibits are nearly as good as the ubiquitous press agents have been telling us they would be for some months past. The car exhibits, with perhaps one single exception, were in place for the opening, and the whole show was ready when it was supposed to be.

As indicative of the more remote future tendencies, the commercial section is very well filled with a fine class of cars, varying throughout the whole range of capacities and running the whole gamut of prices. Not this alone, but many of the pleasure vehicle manufacturers not previously numbered with this crowd either actually or in spirit, make the fact known that they are working on something in this line which will make every one concerned observe the result. Were these cases few and far between, nothing would be thought of them, but in the present instance they are numerous and widespread.

Many more makers take the stand that they are so busy trying to make as many pleasure cars as their agents sell that they have no time to even think of the commercial end.

Most noticeable among the details are the increased tendencies toward thermo cooling, long strokes, block cylinder castings, magneto predominance, and increased percentage of water-cooling systems. All of these—barring long stroke—may be taken as simplifications, which, in a word, is the predominant tendency. Radius rods and torsion tubes are missing, wheels and tires are larger, and all of the little details hardly worth mentioning here are improved, refined and brought up to, or, more correctly, ahead of, date. The present show is a fitting introduction to what is destined to be the biggest and best automobile year for all concerned, 1910.

AND NOW, THE LICENSED SHOW

In that city of rapid transit, New York, those inclined toward the automobile and its parts will this week be given the chance to show their skill in the rapid change line, for following closely upon the A. M. C. M. A. show, the show of the licensed body known as the Association of Licensed Automobile Manufacturers will be opened to the public.

Among the ranks of the latter, the percentage of makers catering to the class of buyers who inquire the price last instead of making it the controlling factor is much greater than at the show which will just be closing at the time this one opens. This higher percentage of higher-class cars without a doubt will give the latter exhibition a somewhat higher tone; the cars themselves will doubtless be more elaborate and more highly finished.

Then, too, the setting in the historic Garden—now, if rumor can be believed, about to be razed to make place for a more prosaic structure—has always been such as to attract many who would not visit the other house. All this combines to throw about the A. L. A. M. annual exhibit a glamour which there is no gainsaying. This is very desirable to the exhibitors, for the bigger the attendance, the bigger the sales, if not at present, at least in the near or more remote future. The whole spells more business, which in the last analysis is the actual reason for all shows of this character.

ANNUAL MEETING SOCIETY OF AUTOMOBILE ENGINEERS

THE fourth annual meeting of the Society of Automobile Engineers—first session—was opened on Tuesday at 10 a. m. in the Assembly Room of the Automobile Club of America. The meeting was attended by about thirty members, President Henry Hess in the chair. The morning session was given up to the discussion of various matters for the good of the society, including the appointment of automobile publications to receive and publish the papers of the society, arrangements having been made by the council whereby the publishers of the leading automobile papers contribute largely to the funds of the society for the use of its technical papers and other material.

On adjournment of the morning session the members of the society were tendered a luncheon by the Automobile Club of America in the grill room adjoining the meeting room, which occupied the attention of the members until the meeting in the afternoon at 2 o'clock, at which time, in the regular order of business, the following papers were read and discussed:

The effect of frequent and heavy charging upon pasted lead peroxide plates, by Hugh Rodman.

A graphic determination of chain-speed gear-bearing loads, by L. C. Freeman.

Characteristic curves of internal combustion motors, by B. D. Gray.

These papers proved to be of unusual interest because they were of a character which might well be designated as "all meat." The storage battery paper was apropos in view of the wide activity which now dominates the electric vehicle situation, and the paper, when published, should prove of exceeding value, particularly to those who have the maintenance of electric vehicles within their charge. It will, of course, have a secondary interest to the owners of electrics. The paper in relation to chain-speed gear-bearing loads, while it is of a technical character in accentuated form, is most comprehensive, nevertheless, and covers divers important points, clearing up things in relation to which engineers have been in controversy.

Mr. Gray's exposé of the characterictic curve situation has the especial merit of tersely pointing out conditions which should lead to a final and better understanding of the abilities of internal combustion motors, and the paper should lead to intelligent and profitable discussion, which is what Mr. Gray hopes to bring out.

At the close of the technical session the chairman announced that a paper discussing some causes of failure of automobile gears would be read by Dr. Sargent at the January 13 meeting.

WHAT IS TO BECOME OF THE A. C. A. DYNAMOMETER

It will be remembered that the A. C. A. installed a special automobile testing dynamometer, which was designed by Dr. Schuyler Scatts Wheeler and installed at the club with the expectation that it would serve as a means by which club members, when they purchased automobiles, would be able to ascertain if the makers lived up to the expectations of the purchasers. This dynamometer is a most ingenious device, capable of many things, and what to do with it is the matter which was broached at the meeting to-day, with the hope, perchance, that this body of engineers, collectively, might be able to suggest a method by which the excellent virtues of this testing machine could be spread out over a more diversified zone of usefulness.

Alden L. McMurtry, chairman of the technical committee of the Automobile Club of America, invited the members to witness tests of an automobile type motor and also a radiator in the laboratory of the club, and an adjournment was made to the top floor of the building where the testing appartus is installed. Mr. McMurtry said that the question of making certain changes in the club's dynamometer was being considered by the technical committee of the club. It had been proposed to adapt the instrument to take power readings from the hubs of the rear wheels of a car under test instead of transmitting the power by the contact of the rear tires with wooden drums. In this way the error introduced by the condition of the tires would be eliminated.

In a general discussion of the dynamometer in which the members of the Society were asked to express their views, Mr. Cave suggested that automobile builders be requested to submit cars from their factories which would be typical of their average practice, and tests made with these cars could be adopted as standards for comparison. It would thus become possible for a user of any car to have it tested and its performances compared with those of the standard factory car, so that any deficiency could be noted.

It is understood that the board of governors of the club contemplates the sale of the dynamometer in case the proposed modifications are not put into effect.

Pursuant to notices sent out by Secretary Churchward, the first of the two annual dinners to be held during the Shows was held in the Grill Room of the Automobile Club of America at 8 o'clock. About sixty members and guests were present, after which the meeting adjourned until the second session to be held at the Engineering Societies Building, on January 13, which will be followed by a dinner at the Engineers' Club in the evening of the same day, after which the Society will be turned over to the new officers for the ensuing year.

It was a graceful act on the part of the A. C. A. to place its beautiful club house at the disposal of the engineers, but the board of directors of the club reached the hearts of the S. A. E. membership through the most diplomatic channel known to man, which took expression by way of a mid-day luncheon, which very aptly bridged over the recess which was taken at that time. In recognition of the splendid hospitality of the club, the Society, before the termination of the evening at the banquet, tendered a vote of thanks to the A. C. A.

FUTURE OF THE SOCIETY LOOKS BRILLIANT

When the Society of Automobile Engineers first started, and A. L. Riker took the presidency over five years ago, it was a baker's dozen of enthusiasts who assembled there and bravely assumed responsibilities of charter members. To a casual observer the situation looked discouraging in view of the then activities of the mechanical branch of the A. L. A. M. These staunch advocates of an absolutely independent and untrammeled society used excellent material for a foundation, and after events proved that an association of engineers to accomplish the most good must enter the assembly hall dressed in their own minds, and free to express such sentiments as they may care to voice, with a feeling of perfect independence, enjoying the distinction of doing as they see fit.

Commercialism has never been welcome in this Society; it stands for abstract engineering, and it has in its body upwards of 300 members at the present time, they coming from the engineering offices of the most representative companies who are devoted to the building of automobiles in America, and to some extent from abroad.

The Society has what is designated as an International Membership, which permits engineers from foreign societies to take out a membership in the S. A. E and to participate in the advantages which are derived therefrom.

SALIENT FEATURES OF THE A. L. A. M. SHOW

OPENS Saturday evening, January 8, and closes Saturday, January 15. The show is open to the public daily, except Sunday, from 10 a. m. to 11 p. m. Society days are Tuesday and Thursday, when double admission will be charged.

Three hundred and twenty-three exhibits, including gasoline, electric and steam pleasure and commercial vehicles, chassis, bodies, motorcycles and all sorts of parts and accessories, machine tools, automobile apparel, etc.

Forty-two exhibits of standard American pleasure cars; 12 exhibits of commercial cars, delivery wagons, trucks, buses, taxicabs, ambulances, fire wagons, etc.; 23 exhibits of motorcycles; 243 exhibits of accessories and parts.

Total value of exhibits, $2,250,000, $250,000 more than in 1909.

More than $35,000 has been expended for decorations.

Lowest priced car, $750.

Highest priced car, $7,500.

Expected attendance, 150,000 persons.

Expected attendance of carriage dealers, 2,000.

Expected attendance of automobile dealers, 5,000.

One of the most pretentious displays of automobile trophies ever seen in America. Among them are the Vanderbilt Cup, the Glidden tour prizes, the Indiana trophy, the Massapequa Cup, the Merrimac Valley Cup, Brighton Beach 24-Hour Race trophies, the Dewar Cup, Sewall-Alden, Tanforan, Thermoid, Lowell, Fairmount Park, Detroit and Dead Horse Hill Climb Cups.

Decorative scheme—main floor: A Roman amphitheatre. White and gold are the dominant colors throughout the whole decorative scheme, although green and crimson are also strongly in evidence. More than 7,000 yards of blue bunting are used for a canopy, concealing the girders of the roof. A score of arc lamps with colored shades hang from the roof, and thousands of incandescent lamps twinkle in the canopy. Over 6,000 square yards of carpeting are used for flooring of the car exhibits.

Thirty Doric columns, each 25 feet high and topped by the show emblem—an eagle on a wheel—add to the beauty of the decorations. Fifty ornamental lamp-posts mark out the spaces on main floor and thirty on the elevated platform. A decorative Roman seat faces the Garden arena entrance. It is backed by an electrically illuminated fountain filled with goldfish and pond lilies.

The Exhibition Hall contains a novel latticed arbor, and an immense rosette and twenty-four white sunbursts hang from center of hall.

The Concert Hall exhibits appear beneath a canvas tent ceiling similar to that of a circus tent.

In the basement a Dutch-Colonial rathskeller, painted in cream white, adorned with autumnal foliage, is a feature.

The exhibition is under the management of the Association of Licensed Automobile Manufacturers. Show committee: Col. George Pope, chairman; Charles Clifton and Merle L. Downs, secretary.

MEETINGS DURING GARDEN SHOW WEEK

The week of the Tenth National Automobile Show, in Madison Square Garden, January 8-15, will be a busy period for the automobile enthusiast and those actively connected with the industry. Many firms and organizations have planned dinners, meetings, etc. Apart from entertainment features there will be a lot of doings of serious sort on the part of various organizations. Events that are scheduled definitely are:

Tuesday, January 11

Meeting of Executive Committee of the American Automobile Association, 10 A. M., at National Headquarters, 437 Fifth avenue. President Lewis R. Speare will preside.

Wednesday, January 12

Meeting of Executive Committee of the National Association of Automobile Manufacturers, at Hotel Victoria, 10 A. M. The annual meeting of the Association will be held at the same place at 11 A. M.

Meeting of Legislative Board of the American Automobile Association, 437 Fifth avenue, 11 A. M. Charles Thaddeus Terry will preside.

Thursday, January 13

Meeting of the Society of Automobile Engineers at the Society's building, 25 West Thirty-ninth street, 10 A. M. At 8 P. M. a dinner will be held.

Meeting of the directors of the New York State Automobile Association, 10 A. M., at Hotel Belmont. President H. A. Meldrum will preside.

Meeting of the Touring Information Board, at headquarters, 2 P. M. Chairman Powell Evans will preside.

Meeting of the Show Committee and Committee of Management of the American Motor Car Manufacturers' Association at headquarters, 505 Fifth avenue, 10 A. M.

Friday, January 14

Second annual reunion of the A.A.A. State and Club Secretaries at headquarters of the Association, 10 A. M. Secretary Frederick H. Elliott will preside. Luncheon at 1 P. M.

The Association of Licensed Automobile Manufacturers will hold meetings during the week, as will also the Importers Automobile Salon.

ENGINEERS WILL MEET IN JANUARY

Meetings of the American Society of Mechanical Engineers will be held in New York on Jan. 11, in St. Louis on Jan. 15, and in Boston on Jan. 21. The New York meeting, which will be held in the Engineering Societies' building Tuesday evening, Jan. 11, just in time to catch all of the engineers visiting the Metropolis then for the A. L. A. M. Show, will discuss mainly lubricating oils and lubrication. The paper upon "Efficiency Tests of Lubricating Oils," by Prof. F. H. Sibley, of the University of Alabama, will be presented and important contributions upon the properties of lubricants, their efficiency, durability, characteristics, etc., will be made by Dr. C. F. Mabery, of Case School, Cleveland, and General Charles Miller, of Franklin, Pa.

This subject of lubrication is so important in its bearing upon the conservation of power and upon machinery of all kinds, especially since the introduction of recent new types, such as the steam turbine and automobile, that it is desirable to have authentic information easily available for the use of engineers.

The president of the Boston Society of Civil Engineers will also outline what his organization has accomplished toward a project that has been under discussion for a united engineering building, to be occupied by the societies in that vicinity.

SHOW SMALL, BUT A BUSINESS-GETTER

COLUMBUS, O., Jan. 3—While the attendance was not all that was expected, the first motor show held in Columbus under the auspices of the Columbus Automobile Club, which closed New Year's night, was a success. The dealers were enthusiastic over the number of cars sold and prospects secured. While it has not been stated officially, the rumor is about that the show will be made an annual affair.

Impressive in the extreme were the closing scenes. All the exhibitors and assistants, headed by the electric cars and the band, paraded the hall before the show was declared closed.

THE STORY OF THE A·M·C·M·A SHOW

WHEN Acting-Mayor McGowan pulled the cord which opened the silken curtain concealing the electrical marble fountain at the end of the main hall of the Grand Central Palace on New Year's Eve, after a short, felicitous speech, he disclosed the central figure in the most elaborate and easily the most spectacular, decorative show scheme ever attempted in the now-famous Palace.

Not only did the show committee of the American Motor Car Manufacturers' Association, which fostered and, in fact, engineered this, the Tenth International Show, set out to outdo previous shows and previous decorative schemes, but what is of vastly more interest, they accomplished it. The main idea of the decorations was that of a garden. With this idea as a starting point, the roof trusses were hidden with a canopy representing a garden trellis nearly covered with growing vines of green.

On the exhibition floors the same trellis idea was carried out, the large spaces of the walls being painted with panels which purported to represent floral scenes both at home and abroad. The lattice or trellis work was made effective and seemingly real by the well-selected colors—Nile green, with a background of Caen stone. Through the canopy overhead, what was apparently the blue sky was to be seen, the colors being well simulated.

Signs of raised Egyptian letters, gilded, on a green background, together with a green floor covering, and very dark mission furniture, carried the scheme through, even to the uttermost corners of the very highest of the many high balconies, for the space demand was such that every available nook and cranny were used.

Although the hour at which Acting-Mayor McGowan opened the show was but eight o'clock—unusually early for the Metropolis—a large gathering was on hand. With such a good start, the attendance has been heavy right through to date, and at the time of going to press it is, if anything, greater than on the opening night.

The first showing of the 1910 cars was well worthy. Despite the talk about lower prices and more low-priced cars, the market as a whole showed firmer in tone, and, if anything, there were as many makers raising prices as there were of those who lowered them. By a natural law of compensation the situation thus adjusts itself, the increases balancing off with the price cutting, so that the man who was looking for a price landslide was left as far from a choice as ever.

Society was out in force at all times, not alone for the formal opening and the equally formal day which followed, New Year's being "dress-suit" day, but at all times the society leaders were there, delighting alternately at the more recent foreign importations and the latest products of American skill and ingenuity. Following the visits of the "400," with which society set its stamp of official approval upon the show, the "4,000,000" making up the proletariat, began to flock in, and they have been flocking ever since.

One of the tendencies shown abroad, at the great Olympia show, to be specific, was the general adoption of the dashboard, radiator and sloping bonnet, made famous and always featured by the French houses of Renault and Charron, popularly called C. G. V. This same tendency was to be noticed, in a much smaller way, however, at the Palace exhibition, one of the most prominent newcomers in the small-car class, listing at close to $1,000, using this useful and highly ornamental form. This, following closely upon the success of a middle Western firm with the same construction, will, without a doubt, pave the way for the general adoption of more of the same.

While the small single sales have not been large, or, to be more exact, have been very small, this is a method of selling cars which nearly every manufacturer now frowns upon. This is barring, of course, the honor of making the first actual sale after the show is officially opened, for which there was this year, as always, much sharp competition. The small individual sales have been small, but, to offset this, the sales to dealers and agents have been unusually large, and many factories have entirely disposed of the 1910 output in this way.

In this category the number of makers were many, and the sales managers of those concerns were, according to their dispositions, either tickled to death or just the opposite. One manager was complaining that his whole year's work had been cut off short by this show, for the factory capacity was all booked, and so he had nothing to do until plans could be made for the 1911 models and factory production. Being so very busy getting out this year's business getters, there was little prospect of this being settled for a long time, which meant

Central Portion of Main Exhibition Floor Showing Fountain at Western End and Lattice Work Decorative Details

enforced idleness for that space of time. For a hustler, as most sales agents are, this is the hardest kind of hard work.

Saturday was set aside as Army and Navy night. In previous years show managers had to be content with the Army only, but the presence in New York harbor of the big gray Atlantic squadron made the double-purpose evening possible. The blue-jackets manifested an unusual amount of interest, while the officers of the fleet were out in force, not alone on the night set aside for them, but at all other times as well.

When the management set aside Tuesday as Society day, and boosted the price of admission to an even dollar, it was thought that only the care-free rich would "give up" to that extent. Many entertained the thought that on this day a visit would be worth the extra money, for then the crowds would be less and more of the show would be visible to the naked eye. Perish the thought! For whether there to see the cars or to view the Paris (and other) gowns, the fact remains that the crush on that day even exceeded the previous day, to say nothing of those following.

Torpedo, gunboat, bathtub and similar bodies were shown in several of the exhibits and were well and closely examined. It can not be said that the public has taken to them with the avidity which was expected, but still the interest which has been awakened in this form—not a freak, but a useful one—has more than paid the few bringing out this type for their missionary and educational efforts in the body-building line. It is freely predicted that as soon as this form takes hold of the popular fancy all other previous styles of fast runabout bodies will become obsolete.

Sharing the automobile world topics of conversation with the big show at the Palace were the private shows. These were more numerous than ever before, and were not confined to the largest and most exclusive salesrooms by any means. The unusual demand for space had led Manager Reeves to lessen some of the spaces, this at a time when the exhibitors would have been pleased to get addititonal space. The result was that many makers changed their exhibits several times during the course of the week, one commercial car manufacturer changing his entire seven vehicles for seven additional and different ones during the eight days of the show. Most of the larger members of the foreign contingent followed this example, showing in this manner twice as many cars as would otherwise have been possible. The private shows along Broadway's Automobile Row were thus bigger and much more numerous than any previous two or three years taken together.

Summing up, it may be said without any poetic license that this year's A. M. C. M. A. Show will go down into history as the biggest and best ever. Manager Reeves and his corps of capable assistants may well be proud of their work, for the exhibit which opened at the Palace on the last day of the old year easily excelled all of its predecessors in every way.

GIST OF THE PERTINENT MECHANICAL FEATURES

INTERESTED spectators, being the possessors of much mechanical skill, particularly of the character which relates to automobiles, see through the proverbial twenty-one applications of "rough stuff" and "finish," and they see right. Before taking up the strictly mechanical features of the running gear proper, spectators were afforded a wide opportunity to examine the body creations of the year, and many of them were, no doubt, interested greatly in the little cars and their natty types of roadster bodies, observing that the steering wheel had a rakish tilt, and that the seat was set back close to the vertical line of the front of the rear wheel for the back of the seat, and the gasoline tank, round or elliptical, occupied the balance of the space.

These types of bodies were very cleverly exemplified in the Model Q Maxwell, Paige-Detroit, and the friction drive Cartercar. In the Mora 20, however, instead of a gasoline tank back of the driver's seat, a trunk, of nice design, occupies this space. The Hupmobile has a perfectly oval tank to the rear of the driver's seat, and, it being finished with the body, makes for the whole show much of style and contrast. The Brush runabout, of the racy type, has a gasoline tank above the chassis line back of the rear seat, but purchasers are offered the option of the same type of car with a platform to the rear of the seat.

Among the toy tonneaus which attracted the notice of a discriminating audience, the Model K 10 Pullman offered evidences of refinement by way of a wide side entrance, luxurious upholstery, and fine finish. The Atlas 60-horsepower two-cycle was fitted with a long and low toy tonneau, the effect being brought about by the short height of the underbody, overhung dash, and long bonnet. The Cole "30" was commented upon favorably by the many visitors who observed that the foot room for the driver was very ample, and that the control system in this car is very nicely situated. Moreover, while the car ranks as a toy tonneau, nevertheless the commodious rear seat, with its rich upholstery, puts it in a class which, a year or two ago, would have been looked upon as a monster touring car. One of the Marmons in the toy tonneau class attracted a great deal of notice for all the reasons of fine body construction, and particularly on account of the commodious side entrance, excellence of mudguards, and fine finish. The Gaeth Type XXI was one of the excellent representatives of Cleveland, Ohio, in which the body work partakes of the qualities of a hunting gold case for a chronometer.

TORPEDO TYPES OF BODIES IN EXCELLENT PRESENCE

The automobile public has been expecting something by way of torpedo types of bodies, and they were not disappointed. The

Main Exhibition Hall of Grand Central Palace, Looking Toward the Main Entrance at the Eastern End

Section of Main Floor Devoted to the Pleasure Car Exhibits

Stoddard-Dayton was there, it being with almost a perfectly smooth exterior with two wide side entrances, an overhang dash, and a rather abrupt rear termination. The curve of the overhang of the dash presented a neat appearance, being shaped to act as a "dodger," thus deflecting the wind upwards and above the head of the driver.

The Speedwell torpedo type of body, as exhibited, proved to be in some contrast, due to the flattened overhang of the dash, and the effect on the general appearance of liberal-sized mudguards, flaring down to the chassis frame, and serving a very useful purposes, besides a pleasing effect.

The many types of touring cars, looking a little smarter than heretofore, had a liberal sprinkling of steel bodies made by properly shaping sheet steel over stout, suitably ironed wooden framing, resulting in very serviceable work, over which the finish presents all the evidences of carriage refinement, and permanence becomes one of the most conspicuous features. Aluminum body work is on the highest possible plane.

SYSTEMS OF IGNITION UTILIZED

Without attempting to definitely place the respective systems of ignition employed, it will be the purpose here to emphasize what seems to be the positive trend in ignition service, in which magnetos take the brunt of the work in every case, the following makes being in widely distributed use:

U. & H., both in the dual and self-starting types; Remy, Eisemann, Kingston, Herz, Splitdorf, Pittsfield, Witherbee, Hess-Bright, and Bosch. In some cases the Atwater-Kent unispark system takes precedence, and low-tension magnetos obtain in widespark work, as in the Premier. Coils, in supplementary ignition work of the various well-known makes, are used in all excepting a few of the smaller cars in which but a single system, that a magneto, is depended upon.

Demountable rims seem to have taken a hold of the autoing public to a greater extent, perhaps, than any other one feature, and among the demountable rims exhibited there is the Diamond, which is a strictly demountable type, with a considerable space under the clincher so that the silt of the road when it forms into a cement-like paste will not cause the clincher to adhere sufficiently to be a source of annoyance. The Firestone demountable rim has also the detachable idea, and, since the rim fetches up against bevel seats, it seems to offer attractions, judging by the crowd. Then there is the Howard idea, in which a worm and wheel, when given motion, causes a right and a left-hand thread, turnbuckle fashion, to tighten or loosen the rim, merely depending upon the direction of turning. The Michelin demountable rim, using a clincher without a brake, is held in place by means of lugs, with through bolts, and the Universal demountable rim has a brake in clincher, thus bringing it in the class of demountable and detachable, and a very novel system of locking, which is actuated by means of a socket wrench, tightens or loosens the rim on its supplementary band with almost no effort, but the security offered is adequate for every need. The Nadall demountable rim is also detachable, in which the clincher is parted, and the two halves are mounted on a supplementary rim, which in turn is locked after being sprung into place, and the whole, with the tire inflated, after it is put into place, is slipped over the felloe and fetched up into place against 45-degree bevel faces by means of alloy steel clamping bolts in such a way that bending moments are absent.

NON-SKIDS MUCH IN EVIDENCE

From the Firestone, which prints its trade-mark as it goes along, to the Morgan & Wright, which has the embossing in rounded quadrangle formation, is a considerable distance to a casual observer, but the principle is the same in either case, and from the latter to the Republic staggard tread represents but a difference in the manner of placing the embossed figures. Then there is the Ajax non-skid, with a diamond formation, but with this difference: instead of the figures being embossed, the grooves between the figures are sunk. The Calmon is of the conventional form, studded, and the Kempshall, which is called an anti-

Another View on Main Floor That Showed Careful Arrangement skid, takes on the appearance of efficiency. From these and other types of non-skids to the Goodrich-Palmer tread idea, which is very popular in connection with electrics, represents the two extremes in tires as they are used in automobiles, in which the non-skid types are considered essential to comfort and safety in connection with touring cars, and the Palmer web, with its ten light plies, offers attraction in that the tire losses are reduced to the absolute minimum, and life is sufficiently long to answer every practical requirement.

Here the Aisle Was Wide, Affording Opportunity for Inspection

Much of the tire success which has been observed of late is due to the use of larger diameters and greater sections. In other words, it is better to pay twice as much for tires, if they will last four times as long, and there seems to be no doubt about the lasting qualities, when the sizes are sufficient to carry the weight without flexure to more than a nominal extent.

In wheels, despite the claims of some, the second-growth hickory employed, which comes from Missouri, is of an unexceptional grade. In view of the circulation of canards in relation to the scarcity of this grade of wood, it comes as a surprise, in a way, to discover that automobile wheels, almost without exception, are selected with the utmost care as respects this material.

Twelve spokes are the rule; they are nicely shaped, and dished wheels take precedence in the majority of cars. Hubs are from drop forgings, or steel castings, and roll on annular types of ball bearings in some cases, conical roller bearings in other examples, and the Hyatt flexible type of bearing finds a wide use in live rear axles.

EYE SECTION DROP FORGED FRONT AXLES

Eye-section front axles are now in such common use that they may almost be regarded as standard. Fortunately, they are drop forged in one piece, thus eliminating welds, utilizing highly kinetic material, usually basic in its characteristics, with well-regulated carbon, and low in metalloids. Steering knuckles are of the several well known types with hardened metal pins, bushed, and grease cups are present in nearly every case.

of traveling of the mixture in route to the combustion chamber is greater than the rate of flame propagation in the body of the mixture itself within the intake manifold. In all events, the power plants, as they were exhibited, taking them as a whole, embodied such fine details as the proper proportioning of the intake manifold, thus assuring that the speed of the gas en route to the combustion chamber will exceed the speed of the flame, and overlapping in the valve timing becomes practicable.

Well-regulated compression aborts carbon formation in so far as coking out will transpire in the gasoline component of the mixture, and this particular improvement eliminates to a very considerable extent the contention that lubricating oil is at the bottom of carbon trouble. On the exhaust side of the motors, taking them in general, there are finger prints of the fine Italian hand of the designer which indicate that the ejector idea is stalking forth, and, instead of a considerable back pressure, which kills power, there is something of a vacuum which coaxes the spent products of combustion away from the combustion chamber, thus adding materially to power and flexibility.

Just now there is a tendency to utilize the nozzle idea in connection with the exhaust, and it has been found by experimenting, and through experience, that the idea is good.

DETAILS OF POWER PLANTS

It is extremely interesting to pass along from booth to booth and listen to the arguments of the clever salesmen who, in explaining the top features of their products to a receptive audience, delve into technics, with never a thought as to whether or not the audience is familiar with this strange and weird language. Perhaps they have learned, some of them to their sorrow, that the audience is fully alive to the difference between a needle valve in a carbureter and a gudgeon pin for a piston. Maybe they learned, perhaps too late to save their dignity, that this same audience grasps the idea of the overlapping valve, and knows perfectly well that popping in a carbureter is not at all due to weak mixture; that popping in a carbureter will not take place at all if the speed

ADDITIONAL REASONS WHY ONE SHOULD BUY

IT has been truly said that show time is not slow time, for at that season of the year makers, selling agents, advertising men, and even the editorial staffs are very busy, too much so to attend to everything. In this hustle and bustle something must be overlooked. It never fails. So it happened that many of the "Reasons" intended for last week's issue reached us too late for publication. Many of those used, too, were not written especially for this column, as had been intended, which accounts for repetition in the late comers given below.

CAMERON: G. N. Jordan, Sales Manager—Of the total number who will purchase automobiles in the United States in 1910, about 90 per cent. will buy for business purposes, and to such purchasers economy is one of the most important considerations; economy in the use of gasoline and lubricating oil, in tire consumption, and in time.

We have designed the Cameron car with these points in mind, sliding gear system), especially in the hands of inexperienced operators.

The high efficiency of the transmission on all speeds is an important factor in keeping down the fuel consumption, and, by leaving off water-cooling apparatus, we are able to reduce the weight of the car 200 pounds, reducing the wear on tires. The car being high powered in proportion to weight, will start quicker from a standstill, will pick up quicker after turning corners and be more economical in time in getting from place to place, even though driven at no higher extreme speed than the heavier underpowered type of car, which requires a long distance to get under way.

The Cameron car is not an assembled proposition, each part is designed and built to fit the other part with the main object in view of giving our customers the most economical car on the market; and, by economy, we do not mean fuel economy alone,

Section of the Main Floor on Forty-fourth Street Side Where Many Middle West Makers Were Located

and believe we are offering the most economical and practical car for the following reasons:

No water is carried.

On the Cameron system of cooling the excess heat is carried off by a natural circulation induced by hot air rising from the cylinders as fast as it is radiated, and cold air rushing in beneath to take its place around the cylinder wall.

When the engine is running light very little heat is radiated off and the circulation of air is naturally slow, keeping the cylinder walls at the proper temperature. When the car is driven hard and more heat radiated off, the circulation becomes faster just in proportion to the amount of cool air required and, on being operated under all conditions at an even temperature, develops its power on smaller consumption of gasoline and lubricating oil and gives longer life to the wearing parts of the engine.

The Cameron transmission system is direct drive on every speed; all our cars are equipped with three forward speeds. This gives the operator the proper range of gearing for any condition of road, allowing the engine to be operated at its most efficient speed.

In changing gears, the gears throw opposite each other and roll naturally into mesh without the danger of wrecking (as in the but economy of upkeep and economy in ease and rapidity of handling. And it is the ideal car for the busy business man who must have highest efficiency, and a car that is always reliable and ready to start regardless of weather condition; a car that can be stored in an ordinary small home garage without heat, and can be left standing indefinitely in zero weather; a car that, when extreme occasions demand, can be driven at terrific speed all day long without overheating, radiators boiling out, causing delay to refill, or other defects peculiar to the water-cooled type of car.

GRABOWSKY: Sales Department—In buying a commercial vehicle, the purchaser must necessarily take an entirely different viewpoint than that taken in buying a pleasure car. He has primarily these facts to consider, ability to give continuous and efficient service, economy and advertising value.

Economy has many factors, the least of which is first cost, if reasonable. Economy of maintenance and up-keep are lowest in the Grabowsky car for these definite and easily proven reasons: Maintenance. The very first requisite of cheap maintenance is absolute accessibility. This the Grabowsky alone has by reason of its removable power plant, in which the motor, transmission and levers are a unit, which slides out or, when out, is shoved

Showing the Distribution of Many Leading Exhibits on the West Side of the Palace, Facing Main Hall

back into the car just as is the drawer of a desk, thus every adjustment is at the chauffeur's finger tips.

Second, the Grabowsky has hardened steel bushings in every working connection. No necessity to renew whole parts at a considerable cost; just replace steel bushings at a very low price.

Third, highest grade of materials used throughout the car. Mr. Grabowsky's long study of and familiarity with steel and iron relative values assures best results here.

The second factor, economy of up-keep, is worth discussing. First, the Grabowsky lubricating system, by means of a vacuum crankcase and a fine application of the laws of attraction, uses its lubricating oil over and over again, thus saving fully one-half the cost of oil.

Second, a two-cylinder opposed motor uses far less gasoline than a four-cylinder motor. Moreover, there is less weight of parts to carry in a two-cylinder motor than a four cylinder and every pound of weight adds to gasoline consumption and maintenance.

The third factor, ability to give continuous and efficient service. This is perhaps the most important feature to the buyer of a power wagon.

The Grabowsky offers continuous service because it is the only car whose entire power plant can be removed and another power plant inserted in the car, a one-man operation requiring hardly 15 minutes. By actual (not theoretical) standardization of parts, every power plant made by the Grabowsky Power Wagon Company fits every Grabowsky truck.

For the use of commercial vehicles, it is only necessary to have an extra power plant (at a small cost) and continuous service of this truck is practically guaranteed. As to power, it is only necessary to show that the Grabowsky is making good in Pittsburg, Cincinnati, the Rocky Mountains, the Allegheny Mountains, the Sierra Mountains (the hardest conditions under which cars can be used) to prove the power efficiency of the Grabowsky.

An Aisle in the Foreign Car Department Where the Importers Displayed Their Products Advantageously

Renault Inside Steering Coupe—A New Type

For these reasons and many others we recommend the Grabowsky as giving unequal satisfaction to prospective purchasers.

MARTIN: Publicity Department, Martin Carriage Company—Economy is the word that makes the Martin Commercial car the most desired.

The strength of a Martin car is economy in every sense of the word. A car that will stand up under its full loading capacity, and not show a sign of weakness, even when under its normal road speed, and equipped with an engine having power enough to run the car loaded to capacity at its normal road speed. A car that inexperienced men can handle with ease, constructed as near fool proof as possible, with gears that can be shifted in a second's time and with no danger to the mechanism.

Martin motor cars can be run through congested streets on high gear, at a speed not to exceed 4 miles per hour.

The riding qualities of a Martin car excel all others, hence every part of the car has a protection not found in other cars.

A motor that has no bevel gears or third chain, not even a belt in its construction, is water cooled and equipped with a mechanical oiler, a simple direct drive.

The Martin car is designed and built by men who know the requirements of a delivery car—men of years of experience in this construction. We back up all this with twenty-five years of experience in vehicles and wagons for transportation purposes.

MIDLAND: E. W. Nicholson—The strong argument in favor of the Midland Model L is the up-to-date design and the careful attention to details in the construction of the Midland unit power plant and system of three-point suspension.

Elsie Janis' Handsome New American Simplex

On the Model L it is absolutely impossible that any of the strains caused by rough and unven roads shall be transmitted to the power plant. By this it is meant that the style of suspension is so flexible that there will be no strains applied to any part of the power plant construction.

This feature is a most decided advance in automobile construction and is being so thoroughly recognized by all who have examined the car it cannot help but prove interesting to the man looking for a car that will give satisfactory service for a long period of time.

A GERMAN ON THE AMERICAN INDUSTRY

Herr Wilhelm Opel, who has recently returned to Germany from a lengthy visit to the United States, has been interviewed by a leading Berlin daily paper as to his impressions. The following is culled from his verdict, which primarily led to a comparison of the state of affairs sixteen years ago, when the industrial development towered high over that of Germany and now, when, during his second stay, Commercial Councillor Opel finds that the Fatherland has caught up to the Republic and that there is no great difference in business organization here nor there. "Nothing," said Herr Opel, "could make me realize more fully the immense strides the German industry has taken than the absolute lack of any surprise during the eight weeks, in which I have inspected American factories, large and small. Over here the industry is on the same level as over there.

"Regarding the American workman as such, I may say he is a specialist as compared to ours, who, in a great many cases, is an all 'round man. But as specialization contains numerous advantages for the perfection of goods, we too are slowly nearing the American method of educating workingmen to this point. Over there this developed of itself, because the workingman himself pressed forward to this end, for, on the whole, he is more intelligent than ours, as a consequence of the racial mixture and the fresh infusion of blood attained thereby. On the other hand, this advantage is equaled by the better education given our working classes by compulsory schooling, as well as the evening classes which are partly obligatory, partly attended voluntarily.

"My chief automobilistic impressions concern the New York motor traffic. Horse-drawn cabs are hardly to be seen, and I venture to predict that in ten years' time horses will have completely vanished from the streets. One city corporation of New York is greatly interested in this problem and chiefly from an hygienic point of view, for the city is surrounded by water and suffers very much from swarms of flies, which naturally were encouraged by the horse, but now this plague is lessening. Motor traffic in the country is almost unknown, for what we would call roads are only met with for short distances; while we still use the highways that were built by the Romans in the middle ages or during the Napoleonic period, the railway was the open-up culture for America and towns and villages were built on either side.

Asked as to the output of the American factories, Herr Opel replied: "During the first days of my stay I was told of factories with an annual production of 12,000 cars. The closer I came to these factories, the more these proud figures dwindled. Every town I stopped at knocked off a thousand or so, till when I arrived at the place in question I learned that, all told, 4,000 would be the figure. There are two or three factories which turn out 8,000 to 10,000 vehicles a year.

"I cannot imagine that we may respect a mass importation of cheap American cars, they have never been able to get a good grip on our market. However, surprises are never excluded in business life. Should an over-production take place, which is not impossible within the next two or three years, the American market may seek to fall itself by force and throw its goods on Europe. But we need not dread this competition. The American car is built too lightly and not rigid enough for our roads."

ON THE TREND OF THE AUTOMOBILE TRADE

By STEWART McDONALD, General Manager Moon Motor Car Company

FORECASTING has always been a very fascinating field for thought and those who are successful in wresting from the future her secrets are, other things being equal, generally the ones who achieve the greatest results in any line of business, for, as the old saying goes, "If our foresights were as good as our hindsights, we would all be successful."

The automobile is here to stay. There may be some differences of opinion as to the type of car, the particular price and size which will eventually fulfill the maximum requirements. There is also some difference of ideas as to the horsepower and motor sizes best adapted, but among any deep-thinking body of men it is bound to be unanimously admitted that the automobile as a necessity is permanent, and its sphere of action will be broadened and developed and the numbers in use multiplied exactly proportional to the quality of cars furnished, the general price, and the improvements in the roads and highways of this country.

The talk about the automobile industry being the natural heir to the calamities which befell the bicycle trade can carry but little weight when it is but once remembered that the bicycle, while it was a vehicle of transportation in a measure, was at its best but a species of gymnasium apparatus, eagerly sought for by the faddists, and as rapidly dropped when the craze lost its popularity.

From all this it is not to be argued that there may not be dark days, and many of them, in front of the automobile industry. However, these, if they come, will be the result of either the greed or the impetuosity of the manufacturers who are at present in the business, in their endeavor to expand their output in undue proportion to the natural market for cars.

What the exact effect even this will have upon the automobile industry, or more properly speaking, on the automobile as a whole, is still another problem and even more difficult to fathom. It would seem, though, that if such events came to pass, the natural result would be that the public, having a larger selection of wares to choose from, would buy with greater discrimination. Granting that the public does not long remain in the dark upon any one subject, it would appear that probably the identical manufacturers at whose doors could be laid the too large and too greedy growth would be the heavist sufferers themselves. Usually excessively rapid growth and thoroughness do not go hand in hand.

The trend of the automobile business is rapidly toward cheaper cars. This is as it should be, as the number of people who can afford a moderate-priced car is infinitely greater than the few who are ready purchasers of a high-priced automobile. It is only right that the greatest development which will probably take place in the next few years will be toward perfecting the car of medium price and bringing even this within more ready reach of the average buyer. A moment's reflection will readily convince the most skeptical of this.

Go away from the large cities, take the towns and villages and realize the enormous field in which the horse and buggy is still utilized. A good horse and buggy totals almost $500, to say nothing of what a fairly good team and surrey would come to. In any instance, one of the moderate-priced automobiles, even at the figures current to-day, would show a greater economy, greater mileage and greater service for a slight increase in the investment, with all the possibilities the future might bring in the way of reduced prices and more efficient service.

With the enormous increase in the use of automobiles is also coming a great development in the average user along mechanical lines. Business, office men and people who are never accustomed to handling anything more pretentious or complicated than a tack-hammer, display a truly intelligent knowledge of most mechanical principles. The intimate learning that even school boys have now, together with the original ideas, which in some instances they possess regarding the real intricacies, is marvelous and indicates that the day is fast approaching when even the boy will look upon the purchase, handling, and usage of an automobile with less forbearance than was shortly before felt by his friends who tackled the proposition with the services of an expert chauffeur.

Marvel has sometimes been expressed at the remarkable manner

In the Commercial Car Section the Display Was the Most Effective and Varied That Has Ever Been Presented

Looking North on an Aisle on the Second Floor

in which medium-priced cars have been absorbed in the good farming States—States where the average land-holder could well afford to be the purchaser of a medium-priced car. The possibilities here, large as they have been in the past, will greatly exceed this in future, as it is in these districts that the automobile comes in for its fullest measure of utility. The automobile is a pleasure vehicle always, and one that does not weary with miles—a device that places the farm within almost neighborly distance of the city—the means of quick communication with stores, shops, doctor, or emergency repairs, and, above all, something, which added to country life, gives it all the conveniences of the city with the charms retained.

Another Section of Second Floor Looking Eastward

Coupled with this has been the natural way in which they "catch on" to cars in the country districts. It has often been wondered why it was that a shipment of 50 cars to a small town where they are distributed to the people living in the vicinity is heard from in the way of repairs so much less frequently than the same number shipped to a large city agent.

The reason is simply that the people living in the country have been accustomed to machinery for a long time—hardly one of fifty owners has not an anvil on his own place. These can make a weld as well as the average journeyman blacksmith. Furthermore, they are more patient and used to thoroughly looking into their various machines and learning the principles thereof and so they naturally take the same pains with their automobiles. Hence, in a very short time, they become as proficient in their adjustments and handling as is the dealer who sold them the car.

The trend, then, of automobiles, as the writer sees it, is toward more and better cars. Probably lighter cars with simplifications in the mechanism taking place as rapidly as developed is a factor which lessens buyer resistance. These all would have a tendency toward a reduction in price, especially as standardization sets in and changes become less frequent.

The development of good roads will greatly increase the use of cars, especially in States where the trade is somewhat backward. However, the greatest development will be the acquisition of a complete knowledge, acquaintanceship and understanding of the underlying mechanical principles. It is not enough then, therefore, for a manufacturer to see that his employees—his agents, salesmen, etc.—are thoroughly familiar with the constructive theory and features, but the real and prospective purchaser, the public at large, should also acquire a thorough familiarity and understanding of the mechanical principles underlying automobile construction.

This, coupled with a healthy growth in the manufacturing end of the business and a steady development of good roads, will take care of the future of the automobile industry.

CHAIRMAN FOR BALTIMORE SHOW

BALTIMORE, Jan. 3—President C. Howard Millikin, of the Automobile Club of Maryland, will be chairman of the committee which will have charge of the next annual show to be held under the club's auspices, February 22 to 26, inclusive, at the Fifth Regiment Armory. Dr. Millikin has appointed as other members of the committee, Thomas B. Hutchinson, assistant chairman and also assistant secretary of the club; Dr. H. M. Rowe, H. M. Luziers, Thomas G. Young and Joel Nassauer. Dealers who desire information regarding the show will be accommodated by President Millikin, 914-916 Equitable Building or Assistant Chairman Hutchinson at the clubrooms, The Garage Building, Mt. Royal avenue and Charles street. Aeroplanes and balloons will be among the new features of the approaching exhibition.

Floor space has already been partitioned off and drawings for the desirable places will be made by the dealers within a week or so. All spaces, with the exception of a few in the middle, will be sold at the same price. Representatives of the show committee have been attending the shows already held and will be present at others to be held with the view of suggesting the latest features for the Baltimore exhibit. The club members held a stag progressive euchre party at the club rooms last Tuesday evening.

CINCINNATI SHOW FOLLOWS CHICAGO'S

CINCINNATI, Jan. 3—The Automobile Club of Cincinnati will hold its show in the Music Hall, February 21 to 26 inclusive. This is the first time that the club has promoted a show. Although applications for space do not close till December 31, more than half of the space had been taken and deposits paid by the middle of the month. Rutherford H. Cox is general manager.

Things that Attract in the Accessory Field

"WATCHMAN, what of the night?" Automobiles by dominance of size and space occupied claim first attention of visitors to the Show. Primarily, they overshadow other exhibits, unduly draw attention, and rob half the accessory subject of its potency as an attraction. In the meantime, when truth is dragged from its lair, and photophobia is thrust behind, spectators may be awakened from their lethargy, and the news may be gently broken: There is not, in all the land, an automobile made in which accessories do not enter.

Some automobile makers claim the distinction of producing 93 per cent. of all that goes into their wares; more hold that they produce all but lamps, tires, radiators, tools, wheels, rims, drop forgings, bodies, windshields, tops, cylinder castings, crankcases, gearcases, crankshafts, etc. These say they build the car complete.

Consistency is the jewel which shines for all but the man who wants to take unto himself credit for having thought out the scheme of the Universe before God wrought parts, put them together, and thrust them out, into the swirl of gravitational influence, branding the whole flock as "accessories."

When the A. M. C. M. A. show opened at the Palace on New Year's eve, the accessory division may have been a little less spectacular, thrust in corners to some extent, and less of interest to the casual observer, but the cars, as they were to be seen, taking them as a whole, were as good as the foundation on which they rested, and it is to the credit of accessory makers, to a very considerable extent, that they bask in the sunlight of favor, and reflect credit upon their sponsors.

The accessory division is a big limb of the tree, even though some would have us believe that it is no more than a twig. Accessory makers are bent upon compounding a permanent reputation for themselves, and they fully realize that, to be successful, it is necessary for them to engrave their crest high up on the face of a granite cliff, rather than in the sands of the shore. Having forged from the solid bar, so to speak, taking pains to apply the "sand blast" of experience and honest endeavor in the process, the accessory makers lighted their lamps of wisdom, wave to magnetos, coils and batteries, their allotted work, lubricated the ways for business, sounded horns, while tires were there in profusion, vying with shock absorbers.

From the Palace to the Garden, will be the move, and when the A. L. A. M. opens on January 8, for a week, it will be with all the Palace accessory exhibitors attending, and many more besides. Never before, in the history of the automobile, has there been such a display of accessories, or such a widely diversified panorama of the 895 different kinds of parts which constitute a full-fledged automobile. Again, it is not a far stretch of the imagination to proclaim that quality presides, good taste sits at the right hand, and catchpenny knick knacks, of which a flock once perched among us, have taken wings as timid birds, lacking in down and feathers.

GENERAL REVIEW OF ACCESSORY EXHIBITIONS

In reviewing accessory exhibitions, it has ever been difficult to arrive at a basis which would afford satisfaction from all angles. One way is to briefly mention each stand, state what it holds by way of a leader, and leaving a good taste in the mouth of the advertiser, at the same time, avoid offense to the sensibilities of the readers. In order to realize the difficulties involved, it is only necessary to state:

Taking the accessory exhibitions at the Palace alone, assuming that there are 238 separate subjects to cover, and allowing that each subject be dismissed with 200 words, it would require just under 50,000 words to cover the exhibits, and as will be readily appreciated, not a single one of the exhibitions would be intelligently discussed, for the reason that, in 200 words, it is not possible to say anything on a basis of introduction, construction and conclusions. It follows, then, that without telling what a thing is for, how it is made, and how well it performs, it is useless to broach the subject at all, much less to dribble out 50,000 words in nauseating puffs, thus destroying the value of the paper, killing the usefulness of the writer, and rendering the audience immune from future attacks, either with truth, truckle, or trend.

RESUME OF THE ACCESSORY INDUSTRY

A comprehensive résumé of the accessory industry, better than a sea of meaningless mentions, will leave the subject in a healthy state, and in the time to come, it will be possible to systematically sort out the accessory features, and by properly spacing them, and using comprehensive illustrations to make good reading for maker and user alike, reflecting credit upon the paper which undertakes the task.

For the time, then, we present the resumé, taking the subjects in rundown order. There is no order of importance on the count that "every link is necessary in a perfect chain."

BODIES, TOPS AND WINDSHIELDS

Comfort in winter automobiling depends in no small measure on the equipment of top and windshield, providing of course that the open touring car is used all the year round. The supply of windshields shown at the Palace is particularly extensive, and indicates a very strong demand for this accessory. It is worthy of note that the old style single-piece shield has practically disappeared; even the cheapest models are hinged in the center. No one who has had experience with the old type will regret its passing.

One concern shows a new shield of this variety at a very reasonable price, in which the glass frames are of wood. This finish is preferred by many people, and is in keeping with the tendency to eliminate brass work as much as possible. The majority of shields, however, are made with brass frames; in many cases these are made very narrow.

These is really no reason why a glass shield should be surrounded with a heavy metal border. Glass is one of the most elastic substances known, and is much harder to break than people generally suppose. Indeed, it is less liable to breakage when unsupported than when held rigidly by heavy metal-work. One shield at least seemed to be built with reliance on this idea, although two other companies also offered exceptionally light and neat constructions.

Means employed for holding the folding glasses in place are almost innumerable, and seem to work on nearly every principle of mechanics. Automatic devices naturally predominate, with many varieties of spring-tension and thumb-screw arrangements. An increasing number are what is called automatic—that is, they can be moved into any desired position merely by pushing or pulling with a single hand, and when set will retain their position. This feature is accomplished usually by a constant-tension spring device.

Another feature which is becoming more prominent is the adoption of eccentrically folding upper glasses, instead of plain hinged ones. This allows the shield to be set with the parts separated, leaving an open strip through which the driver can see the road perfectly even when the rest of the shield is spattered with rain. At the same time the protection is but slightly impaired.

One company has a model especially adapted for runabouts in which the lower glass is slanted back at a considerable angle. Many modern cars have so much room between the front seat and the dash that a straight vertical shield over the latter gives but little protection. This idea of course brings the vertical upper section back into a more useful position.

Tops are shown by two companies, and another has on exhibition a line of its fabrics for tops, which have found general use. Monograms and door-plates are also shown. For body finishing there are varnishes made by two reliable firms. Most of the body builders proper have migrated into the complete car section, by taking the agency for some car which they can fit with their bodies. This tendency is particularly noticeable in the importers' section, as many of those exhibiting there have graduated from the accessory class. The complete list of those exhibiting at the Palace follows:

L. C. Chase & Company, Boston.
Hill Mfg. Co., Buffalo, N. Y.
Ideal Wind Shield Company, New York City.
Metal Stamping Company, New York City.
Moller & Schumann Company, Brooklyn, N. Y.
Pantasote Company, New York City.
W. F. Polson, Buffalo, N. Y.
John A. Salman, Boston, Mass.
Sprague Umbrella Company, Norwalk, O.
Troy Carriage Sun Shade Company, Troy, O.
Valentine & Company, New York City.
Vehicle Apron & Hood Company, Columbus, O.

The following will exhibit at the Garden show only:

Cowles & Co., New Haven, Conn.
Cox Brass Mfg. Co., New York City.
Hayes Mfg. Co., Detroit, Mich.
C. A. Mezger, New York City.
L. J. Mutty Co., Boston, Mass.
National Auto Top Co., New York City.
Novelty Mfg. Co., Waterbury, Conn.
Rands Mfg. Co., Detroit, Mich.
Springfield Metal Body Co., Springfield, Mass.
Vanguard Mfg. Co., Joliet, Ill.

PROFUSION OF HORNS AND SPEEDOMETERS

Automobile horns may be divided into three classes; those of the familiar type operated by air pressure from a bulb, those connected with the exhaust of the engine, and those operated electrically. The "old reliable" type is shown in a multiplicity of forms by one company, including the design with a knob punched full of holes in place of the bell.

Exhaust operated types are shown by two concerns. One outfit is extremely reasonable in price, and has what is described by the maker as a "chromatic scale of bird-like notes." The other company's devices are more pretentious, being made to sound a chord of three notes. The most recent production is the "trumpet," which can be made to sound the army bugle calls. It has four separate tubes, each giving a different note, and controlled from a keyboard. As a warning, all four can be sounded together.

Most modern of all are the electric horns. The latter is one of the most original and efficient devices for converting energy into sound ever invented. It contains a small electric motor with a toothed wheel on an extension of its shaft. The teeth strike against a hardened steel button on a steel diaphragm, causing the latter to vibrate sharply. The process is compared, with reason, to snapping the bottom of a tin can. The diabolical racket that results when the current is full on can be heard a mile, and is guaranteed to produce results.

The other, although likewise electric, does not depart so widely from the ordinary. In this case the motor drives a turbine fan, and the sound is produced by an air blast. A feature is the ingenious magnetic brake, which brings the revolving part immediately to rest when the current is turned off.

Speedometers offer one of the widest fields for the exercise of mechanical ingenuity. Among those exhibited there are three actuated by centrifugal force, one by air pressure, one by liquid pressure, and one by magnetism. One other exhibit seems to elude all classification. This latter, a new device, resembles a clock mechanism, and indicates only the average speed for each thirtieth of a mile, making no record of momentary variations. One great advantage of this construction is that the fastest moving part revolves only 30 times to each mile. Naturally there is no perceptible amount of wear in the parts.

The centrifugal instruments although working on the same principle, differ in many details. Each has some distinguishing feature of merit. One company, as usual, features the "steady hand," and the exhibit includes a device for shaking and jolting one of the instruments to exhibit this feature.

Another retains the familiar magnetic action, and a third the tube full of red liquid and the centrifugal pump to drive it up along the indicating scale. One company has a new idea, in which the instrument is worked by air pressure. No details of the construction are available, but it is interesting simply as another example of the ingenuity which is expended in this branch of the automobile industry. Those who exhibit horns are:

Automobile Supply Mfg. Co., Brooklyn, N. Y.
Gabriel Horn Mfg. Co., Cleveland.
Lovell-McConnell Company, Newark, N. J. m
Nightingale Whistle Mfg. Co., New York City.
Nonpariel Horn Mfg. Co., Brooklyn, N. Y.
Sireno Company, New York City.

The speedometer makers are:

Auto Improvement Company, New York City.
Cleveland Speed Indicator Company, Cleveland.
Hoffecker Company, Boston.
Shipman Instrument Company, Sunbury, Pa.
Star Speedometer Company, Danville, Pa.
Stewart & Clark Mfg. Co., Chicago.
Troy Carriage Sun Shade Company, Troy, O.
Veeder Mfg. Co., Hartford, Conn.
Warner Instrument Company, Beloit, Wis.

The following will exhibit at the Garden show only:

Jones Speedometer Co., New Rochelle, N. Y.
Recometre Co., New York City. m
Riley-Klotz Mfg. Co., Newark, N. J.

GREAT VARIETY OF LAMPS EXTANT

Two noteworthy tendencies may be observed among the exhibitors of automobile lamps, namely, the growing popularity of electrics and the great number of devices to reduce the "glare" or partially eclipse the lamp for city driving. There can be no doubt that the electric lamp is the lamp of the future. Its simplicity of operation and reliability would alone suffice to give it the preference; add to this an economy of operation far surpassing the gas and oil forms, and its triumph is sure. Practically every maker of gas and oil lamps showed electric models, sometimes adapted for electricity alone, sometimes arranged for combinations.

One well-established company showed an electric headlight of very simple and pleasing design, the body of the lamp being a single bowl-shaped piece of drawn metal, without projections except the bracket lugs. One of the latest styles of gas lights is called the "close-coupled," a rather short lamp of large diameter, which should give a pleasing effect in connection with modern body work. Another new idea is a fixture for a gas headlight to hold an electric bulb. The bulb may be swung into focus whenever desired, as for city driving, or may be swung out of the way, without disturbing connections, so as to allow the use of the gas jet. Two other companies also showed electric headlights.

Practically all the new oil side and tail lamps are arranged for the use of electricity if desired. Two makers have an electric fixture which replaces the oil front, and a third has the bulb permanently in place beside the oil flame. This exhibit also includes a good-looking side lamp for closed cars, in the shape of a cylinder set vertically, and a combination electric tail light and number-plate holder, so arranged that the latter is always illuminated to comply with State laws. One shows a combination oil and electric side lamp, but does not feature it so extensively.

Many devices have been brought out to reduce the objectionable glare of the ordinary acetylene headlight. These take the form either of obstructing partly the light, or of diffusing it in better ways. The latter construction is exemplified by a lamp with a front door which consists of a number of lens strips, the front sides of which are ground to a convex curvature. These have the effect of spreading the light out horizontally rather than vertically; when the beam from the lamp is cast on a wall the illuminated area takes the shape of a flat ellipse with the longer axis horizontal. With the lamps in their ordinary position on the car the light from them is kept below the level of a pedestrian's eyes. The only change from the ordinary acetylene lamp is in the door, and the new doors with the lens strips can be obtained separately and put on old lamps.

A very neat eclipsing device has been brought out, which consists merely of a metal disc on the end of a pivoted arm. These are controlled from the driver's seat by Bowden wires, so that when desired the discs may be swung down into the center of the lamp, thus cutting off the strongest portion of the beam. It is noteworthy that the disc swings down behind the jet, not in front of it, as might be supposed. When the disc is down, one looking into the lamp sees only the acetylene flame against a black background, with no more dazzling effect than an ordinary gas jet.

The reaction against excess brass work has been the occasion of the bringing out of a very pleasing new finish. This is known as the "patent leather" finish, giving a metallic lacquer-like lustre, impervious to heat and moisture. It does not need to be polished and requires no especial care in washing to prevent scratching. Several combinations are made; one all black, one a black body with the front door rim left in brass, and another black with nickel trimming. The innovation seems deserving of great popularity. The exhibitors of lamps are:

Atwood-Castle Company, Amesbury, Mass.
Badger Brass Mfg. Co., Kenosha, Wis.
R. E. Dietz & Company, New York City.
Edmunds & Jones, Detroit.
Gray & Davis, Amesbury, Mass.
C. M. Hall Lamp Company, Detroit.
Manhattan Screw & Stamping Works, New York City.
Rushmore Dynamo Works, Plainfield, N. J.

The following will exhibit at the Garden show only:

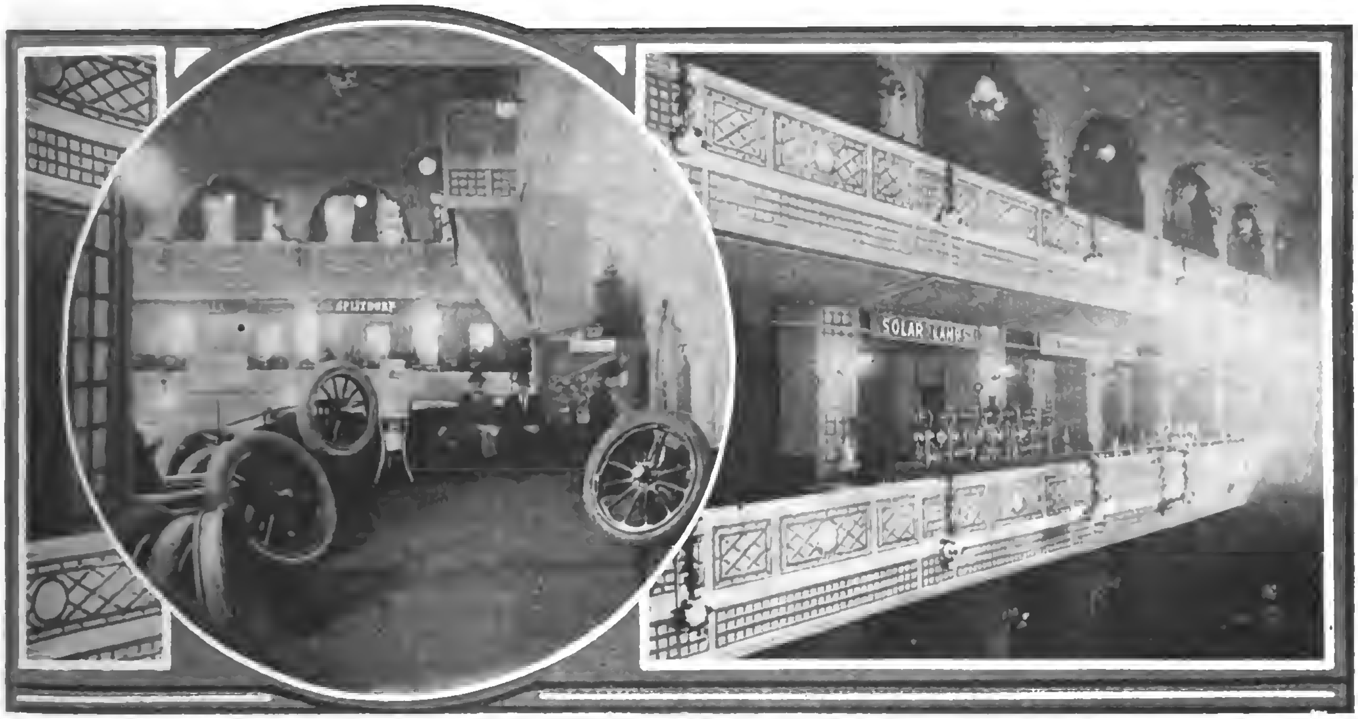
Apple Electric Co., Dayton, O.
English & Mersick Co., New Haven, Conn.
C. T. Ham Mfg. Co., Rochester, N. Y.

TIRES, RIMS, AND ACCESSORIES FOR THEIR CARE

Winter is the open season for non-skid treads, and most of the exhibitors at the show featured this side of their line. The most popular idea seems to be raised projections molded in the rubber tread. These take many forms. Most of the standard makes are furnished with a well-known tread of regularly spaced studs, which has been in satisfactory use for several years. Others have adopted different ideas. One manufacturer has his name molded into the tread in sharp-cornered letters, which are said to be of peculiar efficacy in holding the wheel to the road.

Still another idea is to thicken the whole tread a quarter of an inch, and then mold diagonal grooves in two directions, crossing each other, through the body of this additional rubber. This had the effect of greatly increasing the thickness of the tread, and by consequence its wearing and puncture-resisting qualities. The deep corrugations still leave, however, a large range of flexibility, and so the resilience is not seriously impaired.

Steel-studded treads are also seen in many stands, and the general impression seems to be that they can cope with situations too serious even for the raised rubber tread. The unsatisfactory features developed by these tires in early days have been overcome by modern machinery and methods. They have usually leather protecting bands to hold in place the steel rivets. This leather is specially treated so that it will not lose its flexibility in service; it will neither become soft and spongy nor hard and brittle. The steel studs are turned from soft metal and then chilled by a special process, making them practically glass-hard; in this condition even road grit and sand have but little wearing effect on them. The inside of the rivets still remain soft, so that they will not break off.

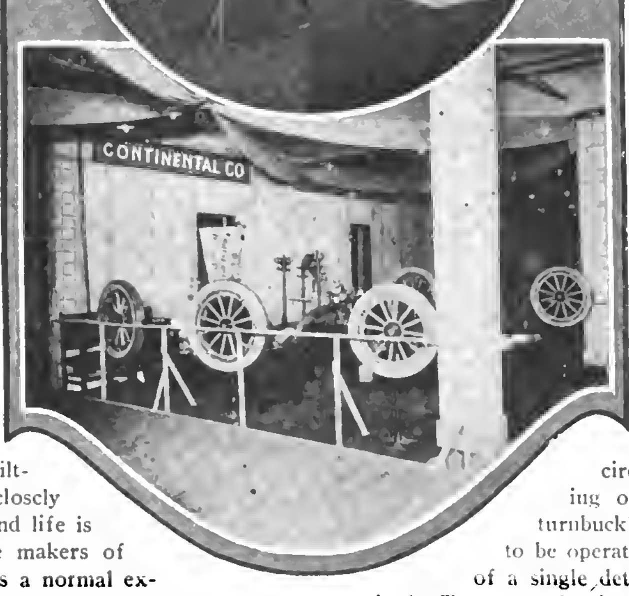


Two Views of Accessory Exhibits in the Balcony, Set Among Original and Artistic Decorations

Makers of detachable anti-skid devices are also present in full force. There are tire chains of every imaginable shape and arrangement. One make has a band of rubber under each cross chain, thus not only protecting the tire shoe from the abrasion of the chain, but also covering a space on each side of the chain and protecting the tire from wear and puncture. In this type the cross chains are about five inches apart. The side chains to which they are attached are flexible and so lie flat against the side of the tire. The side chains have rings on each end, which are connected by a one-inch chrome leather strap. These have buckles, by means of which the chains can be drawn up tight. The ends of the straps are then passed around one of the spokes and made fast, thus preventing the chains from creeping.

It is also possible to secure steel-studded leather covers for the entire tire, which may be applied or removed at pleasure and

AMONG THE TIRE EXHIBITS



give practically the same result as the steel-studded tread integral with the tire. One of these which has good features is held in place by a crimped steel wire on each side. This wire is connected to the edges of the protector by short straps which pass around it and are adjusted by buckles. In this way the cover can be made tight enough to absolutely prevent any possibility of its creeping and chafing the tire.

The very latest thing, perhaps, referring to tires is represented in the new "quilted" casing. This quilting binds the plies of the fabric so closely that it does not detach in service, and life is much prolonged. According to the makers of this new tire, 10,000 miles represents a normal expectation, the increase in distance being brought about by the influence which the stitching has in that it limits fabric trouble and isolates the ills of road inequalities, permitting surface repairs at leisure and aborting blowouts.

Many improvements have been made in the construction of inner tubes, and as a result of this one maker has found it practicable to guarantee his tubes for one year's service. The claims made for the tube proved justified, and no demand was made for replacements under the guarantee. All the tubes returned had been injured by punctures, pinching and other mishaps in no way the fault of the manufacturer or of the tube. The policy has been so successful that it will be continued for another year. The features of construction to which this success is said to be due are enumerated as the use of the best Para rubber, specially compounded; careful cutting of the material, and the making of the valve patch integral and careful curing at the right pressure and temperature.

Demountable rims are proving a fruitful source of inventive activity. There are several at the show that have never been exhibited before, and whatever may be their merits as rims, one and all are the product of remarkable ingenuity. In one of these all the mechanism is confined to a single bolt, which is turned on or off to loosen or tighten up the rim. This makes it impossible to put the tire on in the wrong position. This is accomplished by a worm device actuating a double turnbuckle.

One concern boasts of a combination quick-detachable and demountable rim. The idea is that the rim is ordinarily a demountable one, but if the automobilist should happen to have two punctures in succession, and but one spare rim, the quick-detachable feature will be found very convenient. This device, too, is very simple. The rim is like that of an ordinary clincher tire, but is sawn apart, giving it two ends which may be sprung apart or drawn together so as to make larger or smaller the circumference of the rim. This pulling or pushing is accomplished by two turnbuckles spanning the gap, and arranged to be operated simultaneously by the movement of a single detachable key, which is the only tool required. To put on the tire and rim the latter is expanded until it is large enough to slip easily over the felloe, and then contracted until it is clamped tightly in place. The reverse process accomplishes the removal. To remove the tire from the rim the latter may be contracted still further; this loosens the steel tire retaining ring and allows the tire to be slipped off as on any quick-detachable.

Another rim which is new at the shows looks like a further development of a well-known make of tire. The rim is held to the felloe by six through bolts. The advantages of this type are the absence of narrow wedge-shaped parts, which are always liable to rust and stick.

Cushion tires are seen in at least two forms, both of which seem to have given good satisfaction in the hands of users. One of these resembles a pneumatic tire in every respect except that instead of an inner tube it is provided with blocks of soft rubber inside. A heavy annular rib of fabric runs around the tread of the tire and equalizes the support received from the rubber blocks, so that the tire is of equal stiffness at all points, whether directly over a block or between them. The blocks are of course proportioned to suit the weight of the car they are expected to carry. The tire is built over a steel form or core and is cured or vulcanized in one operation, so that there is no danger of the blocks separating from the solid wall. This tire is claimed to ride as easily as a pneumatic.

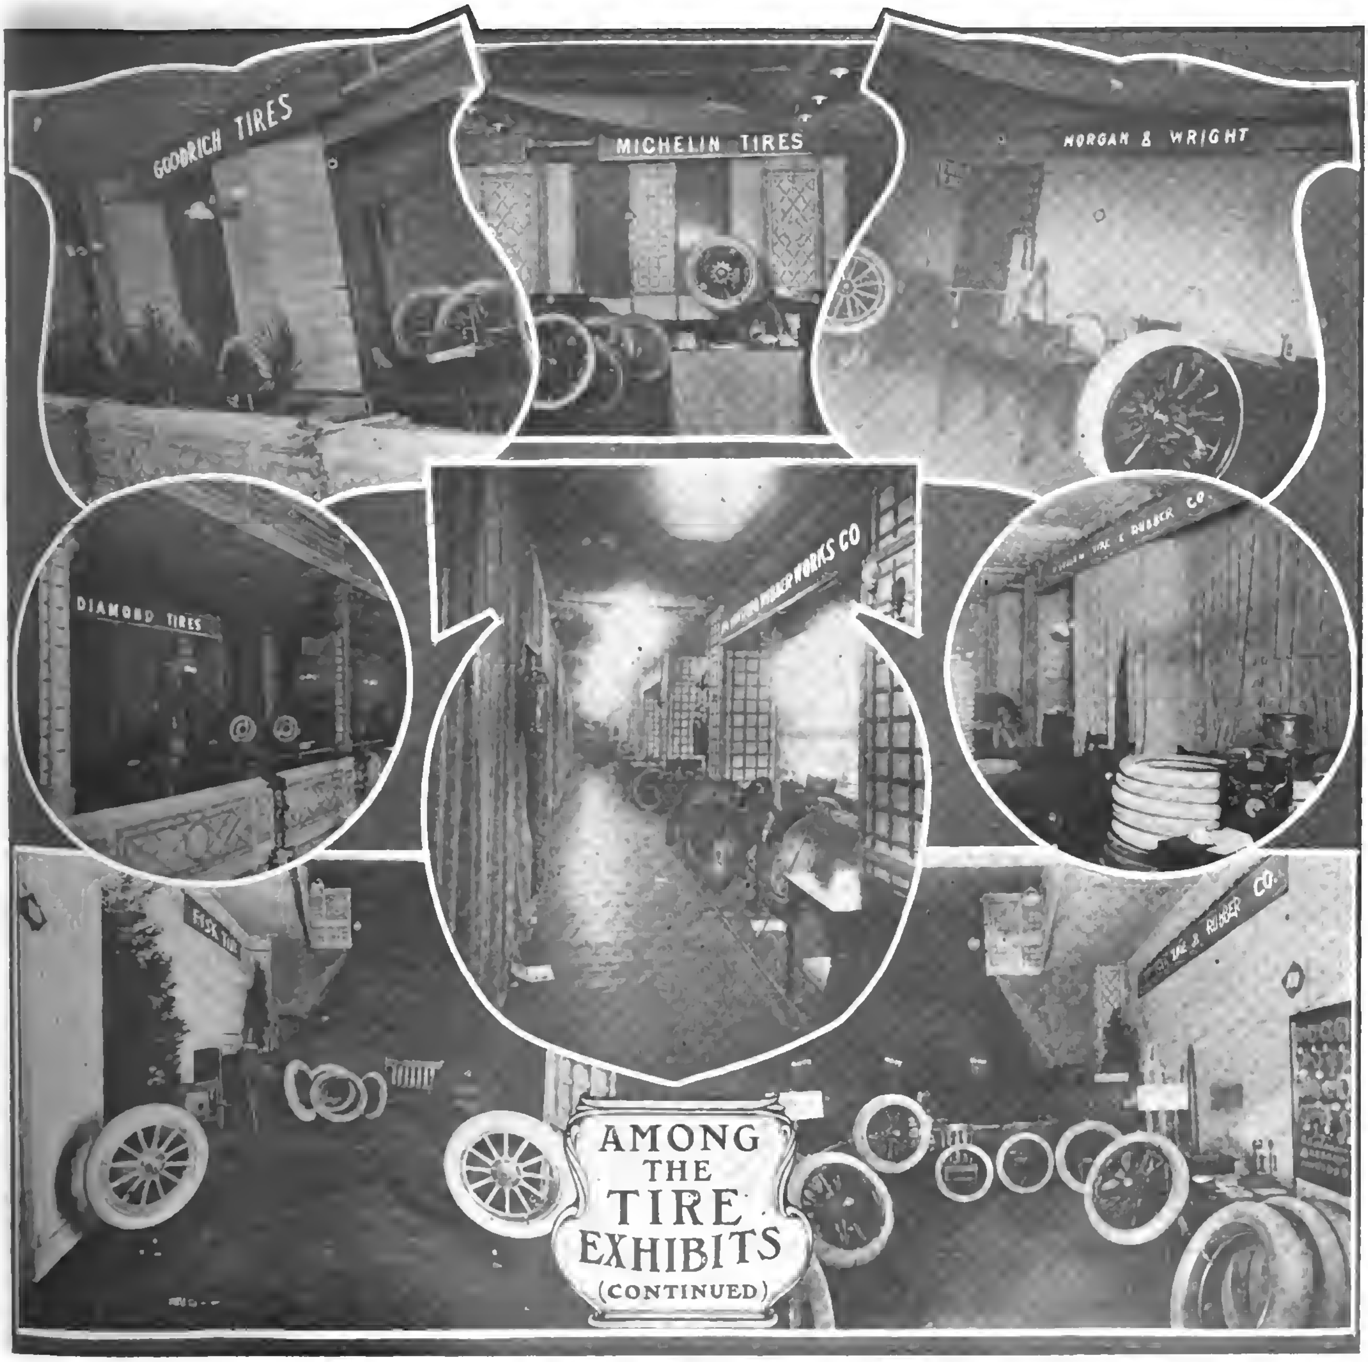
For commercial vehicles one of the most interesting forms is a sectional block tire brought out by a well-known manufacturer of carriage tires who has recently invaded the automobile field. These tires are made up of as many as thirty or forty blocks, square in shape but with beads around the base. These are held in place by a metal frame with square holes through which the blocks project. The frame clamps down on the beads at the bottoms of the blocks. The shape of the tire precludes skidding and gives the maximum resilience possible with a solid tire. These tires are made up to eight-inch dual treads, 48 inches in diameter, suitable for trucks carrying ten tons load.

A very recent development of note in the tire industry is the effort of a German maker who has never before attempted to export to this country. This is distinctively a high-priced tire, and makes no pretension of competing in price with other brands. This is said not to be due to the duty alone, but to the fact that the tire sells for more in Europe than other tires made abroad and competing with it. Like some American tires, it is guaranteed for 5,000 miles' service.

Aeronauts, present and prospective, will be interested to learn that at least one American tire maker is prepared to meet their requirements. Three styles have been brought out, made in a variety of sizes, and in their construction care has been taken to secure the maximum resiliency and at the same time great strength.

For electric vehicles a special tire has been brought out which is claimed to give a much greater mileage on the same battery charge than was obtainable with solid tires. It is a double-tube, with all the flexibility and buoyancy of a single-tube and the strength of a solid. This tire was used on one electric that set a high-water mark of 150 miles on a charge.

Tire accessories are usually of as great interest as the tires themselves, and their efficiency or lack of it often makes or mars the pleasure of a trip. No feature of tire operation is as



AMONG THE TIRE EXHIBITS (CONTINUED)

important as the maintenance of the proper air pressure. One tire maker has brought out a gauge which will instantly register the pressure by merely pressing it over the valve. It is a small and handy device, easily carried in the pocket. A pin in the socket of the instrument forces the valve plunger down when it is applied, admitting the air pressure to the body of the gauge and the pressure is instantly registered on a scale.

To obviate the labor of pumping up the tires, once it is known that they are deficient in pressure, there are innumerable forms of engine-driven pumps and cylinder taps, but one of the neatest devices is that air tank brought out by one manufacturer during the last Glidden tour. This is simply a substantial tank filled with compressed air and provided with a suitable reducing valve, a pressure gauge and a length of hose to make the connection. It can be refilled any number of times, and each filling is sufficient to inflate fully from seven to thirty-five tires, according to their size. Empty bottles are exchanged on the same plan universally used for gas tanks.

The following makers of tires and the accessories involved in their operation are exhibited at the A. M. C. M. A. show:

Ajax-Grieb Rubber Co., New York City.
American Stepney Spare Wheel Co., New York City.
Atlas Rubber Co., Batavia, N. Y.
Batavia Rubber Co., Batavia, N. Y.
Burroughs Remountable Rim Co., New York City.
Caimon Pneumatic Tire Co., New York City.
Consolidated Rubber Tire Co., New York City.
Continental Caoutchouc Co., New York City.
Dayton Rubber Mfg. Co., Dayton, O.
Diamond Rubber Co., Akron, O.
Empire Tire Co., Trenton, N. J.
Firestone Tire & Rubber Co., Akron, O.
Fisk Rubber Co., Chicopee Falls, Mass.
J. L. Gibney & Bro., Philadelphia, Pa.
B. F. Goodrich Co., Akron, O.
Goodyear Tire & Rubber Co., Akron, O.
G. & J. Tire Co., Indianapolis, Ind.
Hartford Rubber Works Co., Hartford, Conn.
Howard Demountable Rim Co., Trenton, N. J.
Leather Tire Goods Co., Niagara Falls, N. Y.
Michelin Tire Co., Milltown, N. J.
Morgan & Wright, Detroit, Mich.
Newmastic Tire Co., New York City.
Pennsylvania Rubber Co., Jeannette, Pa.
Republic Rubber Co., Youngstown, O.
Rutherford Rubber Co., Rutherford, N. J.
C. A. Shaler & Co., Waupun, Wis.
Standard Leather Washer Co., Newark, N. J.
Stevens Co., New York City.
Swinehart Clincher Tire & Rubber Co., Akron, O.
P. C. Traver Mfg. Co., Far Rockaway, N. Y.
Victor Tire Traction Co., Boston, Mass.
Zeglen Tire Co., Chicago, Ill.

The following will exhibit at the Garden show only:

Continental Rubber Co., New York City.
Favary Tire & Cushion Co., New York City.
Federal Rubber Co., Milwaukee, Wis.
Fox Metallic Tire Belt Co., New York City.
Hopewell Bros., Cambridge, Mass.
McGraw Tire & Rubber Co., New York City.
Motz Tire & Rubber Co., New York City.
N. J. Car Spring & Rubber Co., Newark, N. J.
J. H. Sager & Co., Rochester, N. Y.
Seamless Rubber Co., New York City.
Stein Double Cushion Co., New York City.
Voorhees Rubber Mfg. Co., New York City.

SYSTEMS OF TRANSMISSIONS WELL DEFINED

The production of transmissions seems to be to a very considerable extent in the hands of parts makers, and in a general way they may be classified as follows:

(A) Side chain drives.
(B) Selective, three speed.
(C) Selective, four speed.
(C) Selective, two speed.
(D) Progressive, three speed.
(E) Progressive, four speed.
(F) Semi-selective systems.
(G) Planetary systems.

Direct on high gear is the rule, this being true in the examples of planetary as well as when sliding gear systems are employed. If side chain drives are used with direct on high gear systems the reduction from the motor speed to that of the driving (road) wheels, initially, is made by establishing a lesser number of teeth on the different sprockets than on the rear wheel sprockets, and the improvement of the year lies in the use of driving sprocket wheels (pinions) with more teeth than formerly. It is now considered poor practice to have less than 14 teeth in the driving sprocket pinion, and in every possible case 18 teeth are used as a minimum. Contrary to the belief of some, side chain drives are more numerous than ever before, a great array of light runabouts using this class of drive, while trucks as employed in commercial pursuits are almost invariably of the side chain drive genera. Where once there were a few hundred high-priced touring cars built with chain drives, there are now thousands of runabouts that use them. When the writer went through the plant of the Diamond Chain Company, at Indianapolis, a few weeks ago, he expected to see far less than he found; instead of business falling off, due to encroachment of shaft drives, the reverse was indicated in many ways. The plant was full of work, additions in machinery were being made, rearrangement was going on, and an examination of the class of work being done, proved that it was for almost exclusively automobile makers. Reports from the other chain makers are on a level with the conditions as they obtain at Indianapolis, and a conservative statement of fact is that the chain situation is on a better basis than it was when shaft drives were the exception. The following chain makers have exhibits at the Palace and the Garden:

Baldwin Chain Manufacturing Company, Worcester, Mass.
Diamond Chain Company, Indianapolis, Ind.
Whitney Manufacturing Company, Hartford, Conn.

Will be at the Garden only:

Link-Belt Company.

BALL, ROLLER AND PLAIN BEARINGS

"Money talks" in the world of trade, so it is said. In the automobiles of the year, likewise, facts are stuborn things. Ball, roller, and plain bearings are used; none are excluded on the ground of lack of competence, and preference is given, in each instance, with reference to adaptability. It is this adaptability, then, that is uppermost, everywhere, and the specifications, as they would read for some cars, may be given as follows:

(A) Annular types of ball bearings for crankshafts and transmission gears.

(B) Tapered roller bearings for front and rear axles.

In a number of other instances the specifications would read:

(A) Plain bearings for motors, including crankshafts, camshafts, connecting rods, gear-spindles, etc.

(B) Annular types of ball bearings in the transmission gear, tapered roller bearings in road wheels, and Hyatt flexible roller bearings in the tubes, as in the live rear axles.

As a further example of present-day practice, there is the class of cars in which some one type of bearing is used exclusively, as:

(A) Annular types of ball bearings in the crankshaft, camshaft, clutch, transmission, propeller shaft, live rear axle, front axle, steering gear, magneto and ball-thrust bearings where thrust must be resisted.

(B) Plain bearings for the crankshaft, camshaft, accessories, clutch, and starting crank; Timken roller bearings in the transmission gear, propeller shaft, live rear axle, all road wheels, steering gear and knuckle.

(C) Plain bearings in the motor; Hyatt roller bearings in the transmission gear, live rear axle, all road wheels, steering gear and other places.

The tabular story of the automobiles shows a wide range of selection, and, with these facts to be encountered, there remains but the principles of application to be exploited. In the early days of bearings, especially of the anti-friction types, they were regarded of such great competence that, for a given load, the sizes selected were relatively small. The original premests was on a good foundation, and the bearings were of great competence, but there are now two points to be taken into account in the selection of bearings:

(A) Static ability, referring to the ability of the bearings to sustain a quiescent load.

(B) Kinetic ability, which has to do with the life of the materials entering into the bearings, when subjected to shock, vibration, and alternating diagonal stresses.

In the earlier selections, in view of lack of experience from the point of view of kinetic ability, the bearings were large in relation to static conditions, but for kinetic service they frequently fell short of the requirement, and, while many of the applications were perfectly satisfactory, it remains that failure perched on effort with too frequent interval. Bearings, of the anti-friction types, under such conditions, fell into disrepute.

Most of the failures were in bicycle days, and when the automobile was in swaddling clothes. The introduction of annular types of ball bearings, under most careful conditions of selection, marked the turning point, and, by the proper use of appropriate materials, much headway was made in a few short years, and anti-friction bearings solved the problems of the day, among which, lubrication was not one of the least.

There seems to be no limit to the uses to which anti-friction bearings may be put, nor has any one type a monopoly of the good points. What the year's output seems to show is, that every application, no matter what the type the bearing may be, is a success when the bearings selected are large enough to do the work. The applications, being successful, as has been proved, rather go to show that the sizes adopted, for the respective kinds, are adequate.

STANDARDIZATION OF SIZES ALMOST COMPLETED

In the early days, when bearings were largely experimental, there were so many sizes, and such wide deviations in practices, that even the most experienced engineers were frequently in trouble, because of a mal-selection of a bearing. With no previous history, little information, and always the optimism of the makers and selling representatives, it was the easiest thing in the world to make a mal-selection.

This question of standarization is probably the most important step of all. It counts in more ways than were formerly recognized. Every maker, before agreeing to a standard, is bound to make sure that the standard fits the bearings in question. When ball and roller bearing makers, in America, adopted sizes such as were in common use abroad, they surely went to the pains to have the bearings so made, and of such good materials, that they would project favorable history for their sponsors.

One of the best practices of the present day is that of the makers of ball bearings who ascertain, by personal observation, if the bearings selected for cars are in keeping with the conservative ratings given, and, of the reputable makers of anti-friction bearings, none will fill orders if they discover that the uses to which the bearings are to be put, fall short of the practice established as safe. The makers of bearings which exhibited at the Palace were:

American Ball Bearing Company, Cleveland, Ohio.
Hess-Bright Manufacturing Company, Philadelphia, Pa.
International Engineering Company, New York City.
R. I. V. Company, New York City.
Standard Roller Bearing Company, Philadelphia, Pa.
Timken Roller Bearing Company, Canton, Ohio.

The makers of bearings which will exhibit at the Garden will be the same as at the Palace.

Tires and Other Accessories Exhibited in the Balcony Were Many and Well Placed.

LUBRICANTS—FLUID AND NON-FLUID OILS

Oils and greases for automobile use are shown in great variety, and many of the exhibitors have ingenious displays which never fail to excite the public curiosity and interest. In this respect they vie with the makers of ignition apparatus. One company has a gear-box filled with graphite grease, the shafts being rotated by an electric motor, and a crowd gathers whenever it is in operation to look into the slimy depths.

Oils have many attractive exhibits, and are shown in a great number of varieties. The special motor oil of one company is a distilled and highly filtered product, refined from the highest grade of Pennsylvania crude oil. It has a very high fire test. Other grades are known as light, medium, heavy and extra heavy. Motor oil is manufactured for use in cold weather, and makes a particularly appropriate and seasonable exhibit. It remains fluid at a temperature of 5 degrees above zero, and is of medium body. This company's gear oil is an extra heavy-bodied lubricating oil for use in gear cases, where the use of oil rather than grease is desirable. However, to give both possibilities attention, the same concern also makes a semi-fluid gear compound or "dope," which combines the advantages of both oil and grease. Several grades of heavy oil and graphite grease are also included in this line.

Oil is put up in one-gallon cans by the various distillers, is well preserved in them and the means for spouting the same from the cans when it is to be spilled into the oil basin of the motor are secure and handy. The cans are so marked that anyone of the respective grades may be readily had in compact form, and, in a car, it is frequently found desirable to store an extra can of the same.

Another line includes a non-fluid oil, for use in gear cases, composed entirely of mineral oils, and guaranteed not to contain soapstone, graphite or rosin; gear grease, for use in ball or roller bearings, steering gears and axles; transmission compound, for use in differentials and planetary or sliding change-gears, and automobile soap, a neutral linseed oil product.

Many makers are devoting all their attention to different grades of greases. One company is particularly proud of tests recently made in Germany and published by the gazette of the Ministry of Commerce and Industries. In experiments on engines in the coal washing plant at Louisenthal a saving of 43 per cent. over oil costs was obtained, and on shaft journals the saving amounted to 63 per cent. Three factors in lubrication, according to another company, are efficiency, quality and power, and arguments are offered to show that its brand excels in all of them. The exhibitors of lubricants are:

H. T. Alexander Company, New York City.
Connecticut Oil Company, Waterbury, Conn.
Adam Cook's Sons, New York City.
Jos. Dixon Crucible Company, Jersey City, N. J.
Duffy Grease Company, New York City.
Keystone Lubricating Company, Philadelphia.
Havoline Oil Company, New York City.
G. A. Haws, New York City.
W. P. Miller's Sons, Long Island City.

The following will exhibit at the Garden show only:

Columbia Lubricant Co., New York City.
N. Y. & N. J. Lubricant Co., New York City.
Valvoline Oil Co., New York City.
Vacuum Oil Co., New York City.
White & Bagley Co., Worcester, Mass.
Wm. R. Winn, New York City.

PRESSED STEEL AND FORGING ACTIVITIES

Never in the history of the industry has pressed steel been used so much as it is in the cars of this year. Besides side-bars, crossbars, running-boards and divers small parts for chassis frames, there are brake drums, front and rear axles, hubs, caps and a variety of housings, notable among which, the Ford bottom half of the crankcase will serve as a type to illustrate the point made here. In chassis frames, considering sidebars, they belong to classifications as follows:

(A) Straight, channel section.
(B) Straight, U-section.
(C) Narrowed, channel section, without a kickup.
(D) Narrowed, channel section, with kickup.
(E) Underslung, channel section narrowed.
(F) Laminated wood, no armor.
(G) Not laminated wood, no armor.
(H) Armored wood.

The methods of suspending the power plants are divers, and in a general way they may be classed as follows:

(a) On a subframe, motor and transmission in one unit.
(b) On a subframe, motor and transmission separate units.
(c) Eliminating the subframe, motor and transmission as a unit, with a three-point suspension.
(d) Eliminating the subframe, motor separate from transmission.
(e) Arms of motor cast integral, extending to side-bars proper, or to sub-frame.
(f) Separate drop-forged arms bolted to a flanged face, on either end of motor case, and extending across to side-bars.
(g) Separate drop-forged arm at one end of motor; other arm cast integral, both extending across to side-bars.

The exhibitors of pressed steel parts at the Palace were as follows:

Columbia Bolt & Nut Company, Bridgeport, Conn.
Driggs-Seabury Ordnance Company, Sharon, Pa.
A. O. Smith Company, Milwaukee, Wis.
Standard Metal Works Company, Thomsonville, Conn.
Standard Welding Company, Cleveland, Ohio.

The above exhibitors will show at the Garden also.

SHOCK ABSORBERS OPERATE ON MANY PRINCIPLES

Fluid compression is the principle used in two well-known devices; in one air is the medium, and in the other a glycerine mixture. The latter has cylinders with pistons, double-acting, connected between the frame and the axles at four points. On heavy touring cars these cylinders are of a size to hold about one quart of the mixture. The under side of the piston is deeply grooved, and in it are bored two small and four large holes. Their arrangement is such that the downward travel of the springs is not checked unless it is very violent. At the rebound or recoil, the four large holes are automatically closed by a valve. This checks about 85 per cent. of the recoil, and the car body rises slowly. The passengers are not bounced from their seats, and the single upper leaves of the springs, which have the duty of resisting the upward motion, are not unduly strained. Their longevity is thereby materially increased.

The pneumatic device is constructed in much the same way, and resembles the hydraulic check in outward appearance and in its method of application. The air moves from one side of the piston to the other through a by-pass of adjustable area. Owing to the compressibility of air, it is possible to make this by-pass much smaller than the valves in the hydraulic check, and so cushion the shocks by the direct compression of the air.

Another form of shock absorber is that which employs coil springs. There are two methods of employing these, both shown by reputable concerns. In one the coils are interposed between the ends of the semi-elliptics and their hangers, and in the other the coil spring is connected directly between the axles and the frame. The operation of the latter is so obvious as to require no comment. The other uses two coil springs at one end of each of the main springs, the attachment being at the shackled end. The coil springs are arranged so that they work both on the upward and the downward movement of the main springs.

Following is the list of exhibitors at the New York shows:

Ernst Flentje, Cambridge, Mass.
Gabriel Horn Mfg. Co., Cleveland, O.
Hartford Suspension Co., Jersey City, N. J.
Kilgore Mfg. Co., Boston, Mass.
J. H. Sager & Co., Rochester, N. Y.
Supplementary Spiral Spring Co., New York City.

AMONG THE MAKERS OF RADIATORS

This is one branch of the accessory business which is seldom invaded by makers of automobiles, exceptions noted include Rambler, Cadillac, Packard, and perhaps a few others. Radiators are distinctly accessory products, and, like magnetos, coils, batteries, windshields, tops, wheels and tires, are made in enormous qualities, as many as 100,000 radiators being made in a single plant devoted to this class of work.

Radiators, as they obtain, may be classified as follows:

(A) Honeycomb, square, or octagon.

(B) Vertical tube, with gills.

(C) Horizontal tube, with gills.

(D) Flat plate, imitating square tube effect.

Besides these general classifications, there are:

(a) Water circulated by means of a pump.

(b) Thermo-syphon systems.

In the water circulation class will be found:

(aa) centrifugal pump circulation.

(ab) gear pump circulation.

In thermo-syphon systems there are:

(ba) Renault (over the flywheel).

(bb) Regal, with a pocket and means for distributing the water.

(bc) Grabowsky, with a steam space above the water.

(bd) Radiator same as in water cooling but of larger capacity.

Exhibitors at the Palace were:

Briscoe Manufacturing Company, Detroit, Mich.
W. J. Kells Manufacturing Company, New York.
Livingston Radiator & Manufacturing Company, New York.
McCord Manufacturing Company, Detroit, Mich.

The above exhibitors will be at the Garden including:

A. Z. Company, New York.

CARBURETERS SHOW ENCOURAGING IMPROVEMENT

It is important, this carbureter question, and to meet its every angle in the quest for perfection, many manufacturers of many minds have, for inspection and purchase, different forms of this important device, all well fitted for the work, but often varying in construction more than in principle.

A water-jacketed type shows other and somewhat marked characteristics. The water jacket, be it known, is a circular chamber outside the mixing chamber. In this instance the makers claim instant volatilization of the gasoline, inasmuch as particles from the spray which are not volatilized as they issue from (in this instance) a canopy-shaped spray, will immediately turn to vapor upon striking the inner wall which is surrounded by the warm jacket. Priming is simplified for the reason that when the lever controlling this function is raised, it lifts the needle valve, causing a rise of gasoline in the chamber. The overflow by a simple process immediately and automatically primes the motor. The makers claim no flooding, no clogging. A fixed air inlet, controlled by a screw, adjusts the air supply for all speeds, and the manufacturers aver, produces a perfect mixture at all speeds.

TO SECURE MECHANICAL ATOMIZATION

Another device (properly speaking a carbureter accessory) is upon the market which lays claims to efficiency and perfect combustion through a new form of mechanical atomization accomplished through the agency of a rapidly rotating wheel with propeller blades, which is hung within a galvanized iron mesh which atomizes the fuel as it passes into the carbureter. This apparatus is a wheel which sets between the carbureter and the intake manifold. It is said that the gasoline spray and air fed by the carbureter must pass through the wheel, causing it to revolve rapidly. The mesh thrashes it into fine spray, disintegrating the mixture and turning it into an explosive mixture.

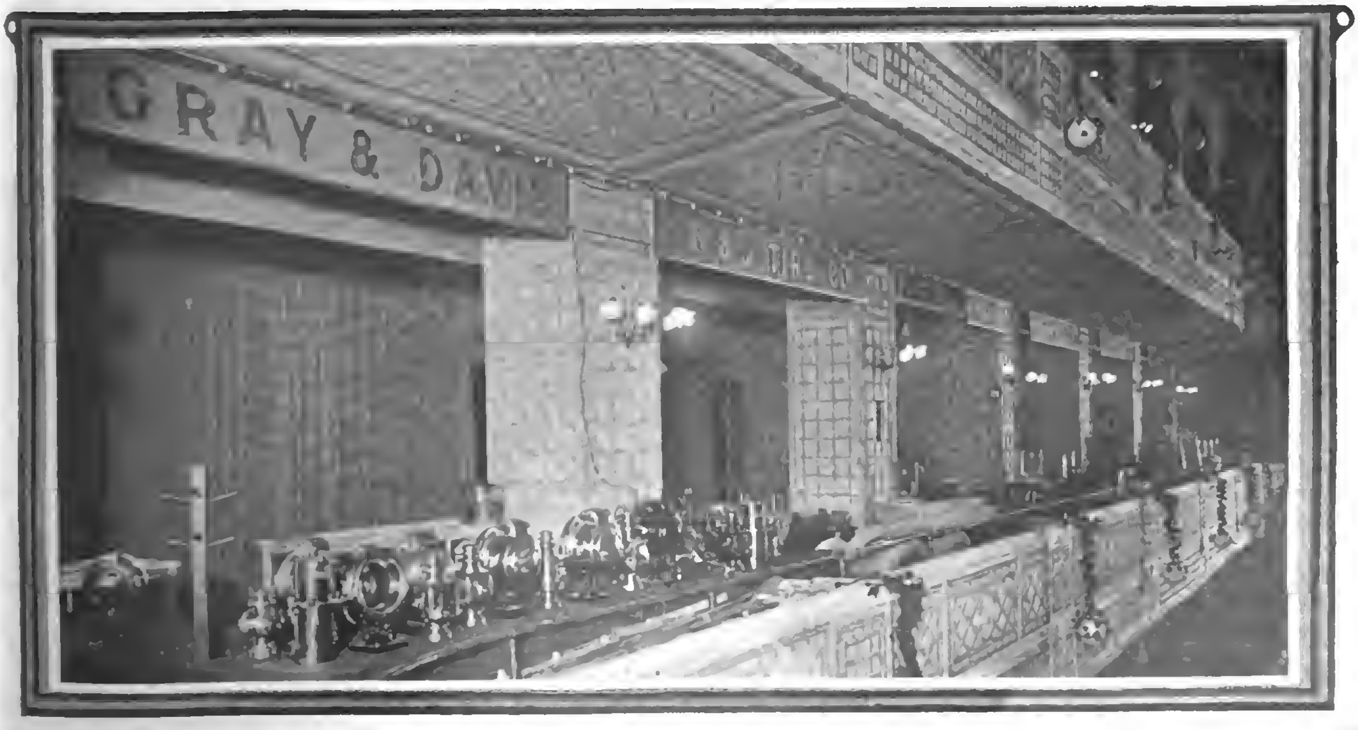
There may be seen on exhibition a carbureter for which many good points have been claimed, among which may be mentioned independent adjustments; a noiseless auxiliary air valve; central draught for main air and gasoline spray, which prevents changing fuel levels on grades, and a needle valve construction which causes complete atomization. It is made in vertical or horizontal form, with a choice of engine connections.

The following manufacturers exhibited at the Grand Central Palace Show:

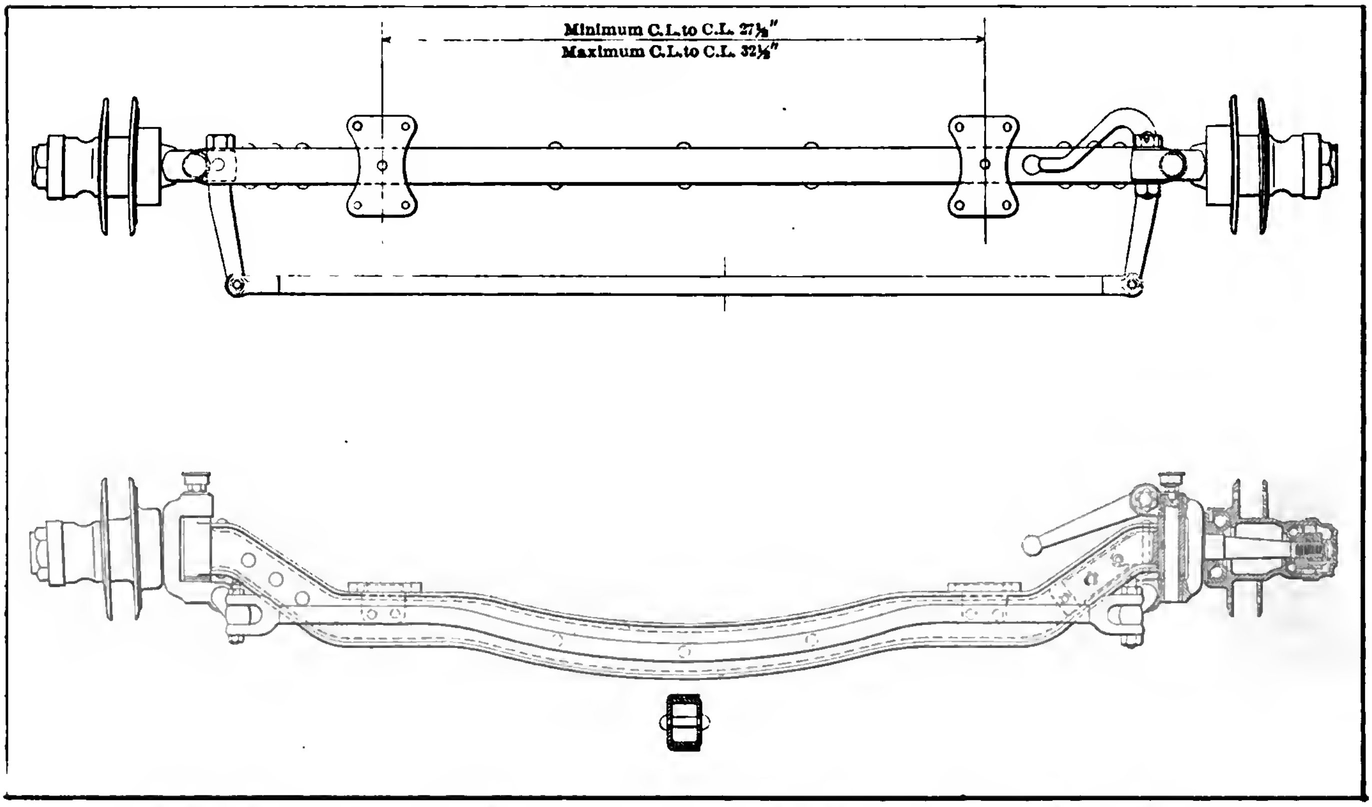
Auto Improvement Co., New York City.
Breeze Carbureter Co., Newark, N. J.
Byrne, Kingston & Co., Kokomo, Ind.
Gasoline Motor Efficiency Co., Jersey City, N. J.
Siro Carbureter Co., Springfield, Mass.
Stromberg Motor Devices Co., Chicago, Ill.
Wheeler & Schebler, Indianapolis, Ind.

The following are exhibited at the Madison Square Garden Show:

Allen Auto Specialty Co., New York City.
Byrne, Kingston & Co., Kokomo, Ind.
Stromberg Motor Device Co., Chicago, Ill.
Waterhouse Co., Boston, Mass.
Wheeler & Schebler, Indianapolis, Ind.



On the Balcony Overlooking the Main Hall Many Leading Accessories had a Vantage Point.



Pressed Steel, Front Axle With Special Steel Knuckles in Riveted Relation as Made at the A. O. Smith Plant

MAGNETOS STRIVE FOR SIMPLICITY AND DURABILITY

Many magnetos represent many ideas and there is presented here a few suggestions covering, in bare detail, the qualifications of this very important device, as it applies itself to modern automobiles.

In connection with the magneto comes a set of spark plugs which together form a complete ignition system. There is no extra coil nor "make and break" apparatus, but cable connections, and an advance lever which locate directly the steering part. The manufacturers state that this magneto forms a standing flame capable of igniting the poorest mixture.

Many points of superiority are claimed for a medium-priced magneto, offering, among other improvements, helicoidally-shaped pole pieces, which it is said permit smooth running of the magneto, prevent demagnetization and allow throttling down and easy starting.

Ready accessibility and great strength are quoted as primal characteristics of an offering in this line. In this instance the magneto has a heavy brass base, supporting two bronze ends, with a triple magnet for the field. The armature is of the Siemens type, with two windings. The makers claim easy and quick regulation, interchangeable parts and a quick hot spark at low speed.

In conclusion it will be well to say that a number of coil makers, realizing the importance of the magneto as a factor in gasoline engine development, have entered the field and are now turning out this latter product with the same attention to detail and excellence which has marked their work in their original field of endeavor.

The following manufacturers exhibited at the Grand Central Palace Show:

Bosch Magneto Co., New York City.
J. S. Bretz Co., New York City.
Heinze Electric Co., Lowell, Mass.
Herz & Co., New York City.
Hess-Bright Mfg. Co., Philadelphia, Pa.
Lavalette & Co., New York City.
Motsinger Device Mfg. Co., Pendleton, Ind.
Nilmelior Electrical Co., New York City.
Pittsfield Spark Coil Co., Dalton, Mass.
C. F. Splitdorf, New York City.
Witherbee Igniter Co., Springfield, Mass.

The following manufacturers will exhibit at the Madison Square Garden Show:

Bosch Magneto Co., New York City.
J. S. Bretz Co., New York City.
Champion Ignition Co., Flint, Mich.
Conn. Tel. & Elec. Co., Meriden, Conn.
Heinze Electric Co., Lowell, Mass.
Hess-Bright Mfg. Co., Philadelphia, Pa.
Herz & Co., New York City.
K-W Ignition Co., Cleveland, O.
Lavalette & Co., New York City.
Motsinger Device Mfg. Co., Pendleton, Ind.
Pittsfield Spark Coil Co., Dalton, Mass.
Simms Magneto Co., New York City.
C. F. Splitdorf, New York City.
Remy Electric Co., Anderson, Ind.

A FINE ARRAY OF MOTORS PRESENTED

Despite attempts on the part of experts to portray the trend in the design of motors in automobile practice, the exhibitions seem to show a diversified state of the art with all the types as follows, represented:

(A) Water and air-cooled motors.
(B) Cylinders with valves in the head.
(C) L-type cylinders.
(D) T-type cylinders.
(E) Individual cylinders.
(F) Twin cylinders.
(G) Cylinders *en bloc*.

It would be impossible here to discuss details sufficiently to serve any useful purpose at all, it being the case that refinements in detail in order to bring them to proper notice, will demand illustrations. The exhibits at the Palace showing complete motors were as follows:

F. A. Brownell, Rochester, N. Y.
L. A. W. Motor Company, Providence, R. I.
Carlson Motor & Truck Company, Philadelphia, Pa.
Excelsior Motor Company, Chicago, Ill.

At the Garden, the motors on show will probably slightly exceed the above list.

TRANSMISSION SHOWN IN DIVERS FORMS

Three speed (with reverse) selective transmission systems are very prevalent. This is shown in the tabulations of cars, both as they were given for the A. M. C. M. A., and as the A. L. A. M. automobiles are presented in the tabulation of the cars which will be at the Garden. It is difficult to put one's finger on the top idea presented. Perhaps the wide adaption of cast iron, as a substitute for aluminum, in the casings, not only for transmissions, but for motors, as well, is the most radical departure of the year.

Certainly cast iron is lighter than aluminum if the measurement is made in terms of strength—true, aluminum is from 10 to 15 times more costly than cast iron, and, as to market conditions, it is cast iron which can be had, more readily, from many sources, and with less risk as to strength.

Gears are now made of alloy steel, in nearly every case, and the equipment used in plants, as gear cutters, planers, shapers, hobbers, etc, are designed to sustain under the work. This is one of the advances of the times, because, in former years, machine tools, as used for shaping gears, were designed to be fashioned on a basis of cast iron, machine steel, etc., and, when alloy steel first came into vogue, it was found that the machine tools were not sufficiently rigid to perform the required operations.

Gear spindles, as prime and lay-shafts in transmission systems, are made as short as possible, and large in diameter in order to defeat deformation which, especially in connection with sliding gears, even though slight, interferes with the working of the system. In matters of this sort, much improvement will be noted all along the line.

As to the materials of which gears are made, chrome nickel steel is present in conspicuous examples. Nickel steel is a prime favorite. Silico-manganese steel is making a name for stability. Vanadium steel is being taken up, and cementing grades of carbon steel are in common use.

Of the exhibitors, at the Palace, the following makers presented transmissions:

Brown-Lipe Gear Company, Syracuse, N. Y.
F. A. Brownell, Rochester, N. Y.
Cotta Transmission Company, Rockford, Ill.
Driggs-Seabury Ordinance Corporation, Sharon, Pa.
Gemmer Manufacturing Company, Detroit, Mich.
Light Manufacturing Company, Pottstown, Pa.
Muncie Gear Works, Muncie, Ind.
A. O. Smith Company, Milwaukee, Wis.
Standard Roller Bearing Company, Philadelphia, Pa.
Timken-Detroit Axle Company, Detroit, Mich.
Warner Gear Company, Muncie, Ind.
Warner Manufacturing Company, Toledo, Ohio.

In addition to the above companies which will exhibit at the Garden also, the following concerns may be included:

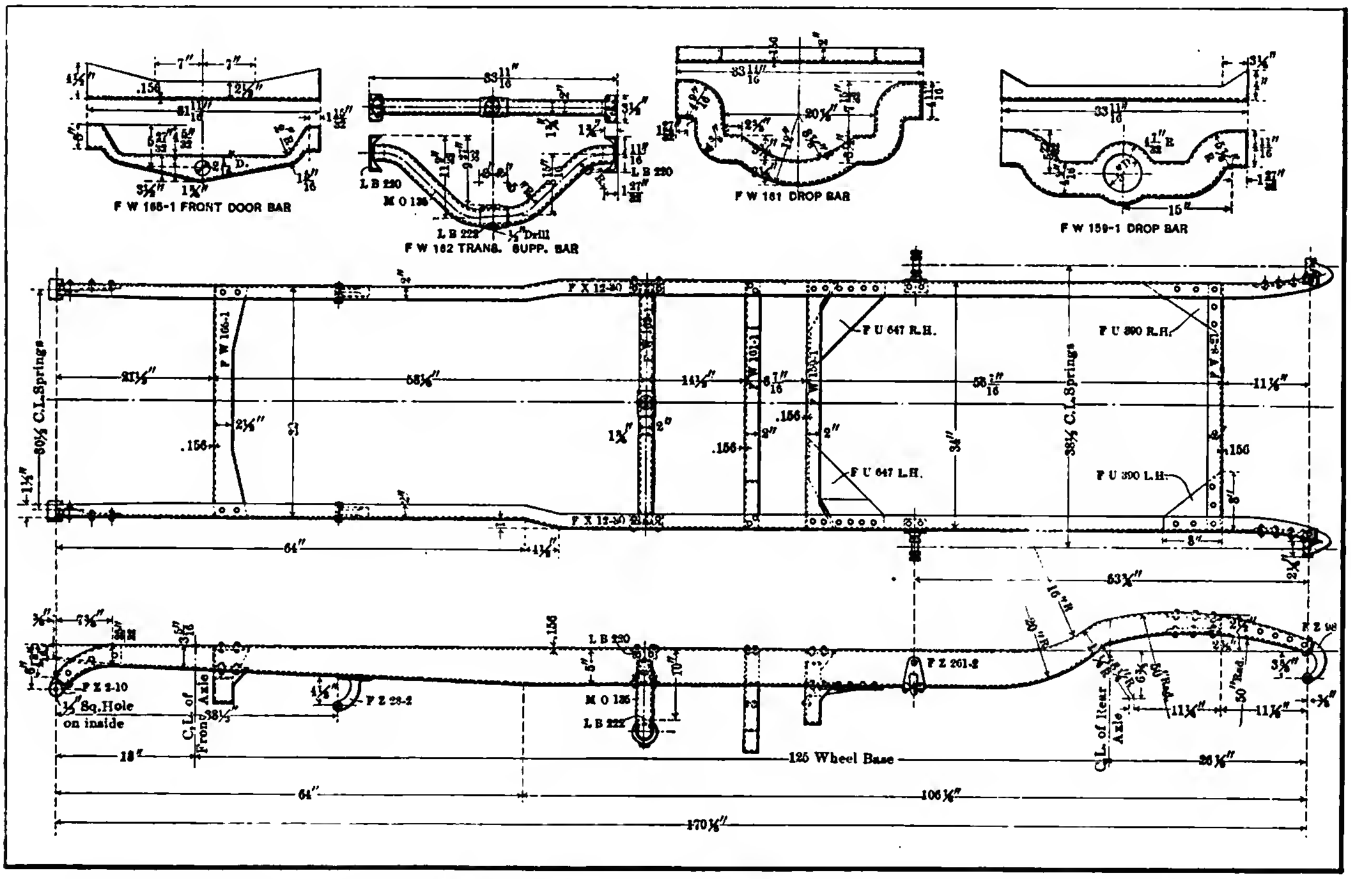
High Wheel Auto Parts Company.

Transmissions are also carried to a considerable extent by the supply dealers, a list of which is given elsewhere.

GRAY IRON FOUNDRIES EXHIBIT THEIR WARES

The extreme importance of cylinder castings and the difficulties involved in their production, considering the quantity requirement in America, has trained up a series of foundries which now produce gray iron castings for automobile work of the first quality. In addition to cylinders, there are pistons and piston rings, crank boxes, gear cases, and to some extent, small parts, all of which, in view of the shock nature of the service they must render, are from carefully selected grades of pig, in the cupola or by the natural draft process, from patterns of competence involving well-made cores, an intelligent "gaffer" and facilities.

In some cases, it is now the practice to mix a certain percentage of steel in the charge, the idea being to increase the average strength of the castings, and refinements made in



Chassis Frame With a Kick-up at the Rear and Special Shapes in the Cross Members Made at the A. O. Smith Plant.

foundry methods render this scheme feasible. The time was when to add steel to the charge was to put up with stout casting but prone to blemishes, the character of which would debar them from cylinder work, in view of the fact that cylinders must be tight as well as strong.

In the shops, with excellent facilities for making hydrostatic tests, defective cylinders are discovered without any question, and foundries are now producing such close grained work that spraying in the hydrostatic test does not transpire, leastwise within the limits demanded for strength. Cylinders are made for both water and air-cooled work with about the same facility, due to refinements in air-cooled designing, and to long practice in water-cooled work. It would scarcely seem necessary here to enlarge upon the problems involved, for if in the past there were difficulties to be surmounted, they do not now seem to deter the makers of cylinders in the leastwise. Among the exhibitors of this character of material at the Garden the following is named:

Erie Foundry Company, Erie, Pa.

SPRING MAKERS IN STRONG PRESENCE

In view of the enormous output of the year, and the fact that springs are almost exclusively in accessory plants, it is normal to expect that this industry will be heavily represented at shows, and at the Palace the spring makers' contingent presented a most pleasing array of the several types of springs.

Distinctive among the exhibits were the designs which include scroll features, they being in three-quarter and full elliptic springs, in which excellence of design included very wide plates, relatively thin members, and retainers of competence. What is true of the display at the Palace will be true of that at the Garden, and it is fortunate that the quality of material utilized in springs is now on such a high plane that spring breakages, which were once prevalent, do not now annoy autoists, unless in emergencies, for reasons that can be traced to something definite. The exhibitors of this line at the Palace were:

New Jersey Car & Spring Company, Jersey City, N. J.
Perfection Spring Company, Cleveland, Ohio.
Thomas Prosser & Son, New York City.

The exhibitors at the Garden in addition to the above will be:

American Vanadium Company, Pittsburg, Pa.
Carpenter Steel Company, New York City.

IGNITION, OTHER THAN THAT BY MAGNETO

Ignition, aside from that furnished by the magneto, covers a wide radius of action and embraces auxiliary features of the magneto as well as independent devices of a like character, and it is the purpose to touch lightly here upon a few of the many devices of this character which are on exhibition at the Madison Square Garden Show. In this résumé, the matter of car lighting will also be referred to in brief, because to do full justice to all subjects mentioned above would require many more pages.

The following makers of ignition apparatus exhibit at the Palace:

American Elec. Novelty Co., New York City.
Atwater-Kent Mfg. Co., Philadelphia, Pa.
Auburn Mica Co., Auburn, N. Y.
Eastern Carbon Works, Jersey City, N. J.
Electric Storage Battery Co., Philadelphia, Pa.
Geiszler Storage Battery Co., New York City.
Heinze Electric Co., Lowell, Mass.
Herz & Co., New York City.
High Frequency Coil Co., Los Angeles, Cal.
Kokomo Electric Co., Kokomo, Ind.
Lovell-McConnell Mfg. Co., Newark, N. J.
Lutz-Lockwood Mfg. Co., New York City.
A. R. Mosler Co., New York City
National Carbon Co., Cleveland, O.
New York Coil Co., New York City.
Osburn Electric Co., Detroit, Mich.
Pittsfield Spark Coil Co., Dalton, Mass.
Remy Electric Co., Anderson, Ind.
F. W. Smith, Aberdeen, S. D.
C. F. Splitdorf, New York City.
Union Battery Co., Belleville, N. J.
Vesta Accumulator Co., Chicago, Ill.
Westchester Appliance Co., New York City.
Westinghouse Co., Pittsburg, Pa.
Witherbee Igniter Co., Springfield, Mass.

The following will exhibit at Madison Square Garden show:

American Ever Ready Co., New York City.
Apple Electric Co., Dayton, O.
Atwater-Kent Mfg. Co., Philadelphia, Pa.
Benford, E. M., Mt. Vernon, N. Y.
Briggs & Stratton, Milwaukee, Wis.
Champion Ignition Co., Flint, Mich.
Conn. Tel. & Elec. Co., Meriden, Conn.
Eastern Carbon Co., Jersey City, N. J.
Electric Storage Battery Co., Philadelphia, Pa.
Geiszler Bros. Storage Battery Co., New York City.
Grossman, Emil, New York City.
Hardy, R. E., Co., Brooklyn, N. Y.
Heinze Electric Co., Lowell, Mass.
Herz & Co., New York City.
High Frequency Ignition Co., Los Angeles, Cal.
Jeffrey-Dewitt Co., Newark, N. J.
Lovell-McConnell Mfg. Co., N. J.
Mezger, C. A., New York City.
Motsinger Device Mfg. Co., Pendleton, Ind.
Mosler, A. R., New York City.
National Carbon Co., Cleveland, O.
National Coil Co., Lansing, Mich.
New York Coil Co., New York City.
Philadelphia Storage Battery Co., Philadelphia, Pa.
Pittsfield Spark Coil Co., Dalton, Mass.
Remy Electric Co., Anderson, Ind.
Splitdorf, C. F., New York City.
Stackpole Battery Co., New York City.
Tray Plate Battery Co., Binghamton, N. Y.
Union Battery Co., Belleville, N. J.
U. S. Light & Heating Co., New York City.
Vesta Accumulator Co., Chicago, Ill.
Willard Storage Battery Co., Cleveland, O.
Witherbee Igniter Co., Springfield, Mass.

AN IMPORTANT MISCELLANY OF STRUCTURAL PARTS

Among the noteworthy exhibitors, especially under the head of structural parts, are many whose wares entitle them to specific mention, notably, the makes of steel castings, among which, at the Palace and Garden, are:

Hess-Bright Manufacturing Company, Philadelphia, Pa.
I. G. Johnson & Company, New York City.
Lebanon Steel Casting Company, Lebanon, Pa.

Among the companies which produce aluminum, brass, bronze and other important casting parts, are:

Brown-Lipe Gear Company, Syracuse, N. Y.
Wm. Cramp & Sons, Philadelphia, Pa.
Doehler Die-Casting Company, Brooklyn, N. Y.
Light Manufacturing Company, Pottstown, Pa.

In addition to the above, there will be numerous exhibitors of this class of materials at the Garden.

SUPPLIES HANDLED BY RETAILING HOUSES

These jobbing houses are of benefit to the automobilist in many ways. They not only discover and bring to the public notice various articles of merit which might never obtain prominence otherwise, but also do a large business in importing foreign specialties.

The catalogs of these companies are often volumes of considerable size, listing within their covers almost everything appertaining to the automobile except the automobile itself.

Among the novelties noted in the exhibits of the supply houses was a very neat little valve lifter, to relieve the spring tension in order to enable the cotter to be removed. This device had two long arms, notched at the ends, to be placed one over the valve lift guide and the other under the spring. These arms were connected at the outer end by a toggle-joint actuated by a thumb-screw. Tightening up the screw forced the arms apart and compressed the valve spring.

The latest thing in the decarbonizer line appears to be a dry powder brand. This is claimed to clean the cylinders and muffler of carbon in less than half an hour. The powder is put up in cylindrical cans, each containing enough to clean one cylinder, and eight cans are sold in a box.

Following is a list of exhibitors at the Palace show:

Automobile Supply Co., New York City.
Emil Grossman Co., New York City.
Chas. E. Miller, New York City.
Motor Car Equipment Co., New York City.

The following will exhibit at the Garden show only:

Detroit Motor Car Supply Co., Detroit, Mich.
English & Mersick Co., New Haven, Conn.
N. Y. Sporting Goods Co., New York City.
Pierson Motor Supply Co., New York City.
Post & Lester Co., Hartford, Conn.

SHOWS DRAW AUTOMOBILISTS FROM EVERY STATE

ATTENDANCE at the Palace included all the old timers, who had made a name in automobile activities, and a goodly sprinkling of the second generation; taking them from the administrative buildings in the many plants, the engineering offices, and the sales establishments all over the land. In some measure, this accentuated attendance is brought about through the small interval which intervenes between the two big shows. Nevertheless, there is a big attendance of autoists, many of whom have a serious bent, but it is a critical audience, and it is making its selection with a deliberation as never before.

One of the old-timers seen at the show was Charles Wridgway, who has just returned from England accompanied by W. M. Letts, of London. The latter is here for the shows and is looking for a good low-priced car to introduce in Great Britain.

F. E. Moskovics was at the show the early part of the week, enthusiastic over the prospects of the aviation meet which he is going to conduct at Los Angeles from anuary 12 to 20.

No show will be complete without the "big fellow from the West," as Pat Hussey is known by his intimates.

Among those in New York representing the Midland Motor Car Company, of Moline, Ill., at the show, are E. W. Nicholson, sales manager; J. E. Miller, engineer; G. P. Hall, who is promoting the car to agents. They are stopping at the Hotel Empire.

The New Grand Hotel is the home of the representatives of the Buckeye Manufacturing Company, of Anderson, Ind., during the show week. Among the representatives of the company here are: J. W. Lambert, president; G. A. Lambert, vice-president, and G. B. Louderback, sales manager.

The Firestone Tire & Rubber Company, of Akron, O., is represented by H. S. Firestone, president; Robert J. Firestone, sales manager, and Frank H. Martin, manager of the Chicago branch. They are stopping at the Hotel Astor.

Harry Brate, sales manager of the Osburn Electric Company, Detroit, is here for the shows and is stopping at the Park Avenue Hotel.

J. O. Heinze, general manager of the Heinze Electric Company. Lowell, Mass., will stay for both shows and is stopping at the Knickerbocker. The same company is also represented by Pierre J. Legare, who is staying at the Hotel Seville.

The Bartholomew Company, of Peoria, Ill., is well represented by J. B. Bartholomew, president; O. Y. Bartholomew, treasurer; G. G. Luthy, secretary; Roy Johnston and R. A. Whitney, sales manager. The Hotel Manhattan is their headquarters.

George E. Edmunds and W. T. Jones of the Edmunds & Jones Manufacturing Company, of Detroit, are staying at the Murray Hill Hotel.

Richard Everett, manager of the Detroit branch of the R. E. Dietz Company, who since his location in the West in the interest of this concern has proven himself a hustler, is stopping at the Hermitage. Allen Cosgrove, the London representative, arrived in New York recently for the purpose of attending both the shows.

The Warner Gear Company, of Muncie, Ind., is represented by A. L. Johnson, president; C. E. Davis, general manager, and R. P. Johnson, secretary and treasurer, who are staying at the Waldorf-Astoria.

The Park Avenue Hotel is the home of C. T. Byrne, president, and J. P. Grace, secretary, of the Kokomo Electric Company, of Kokomo, Ind., during the shows.

George Kingston, president, and Marion Black, are representing Byrne, Kingston & Company, of Kokomo, Ind., and are registered at the Park Avenue Hotel.

L. W. Collins, secretary of the Vesta Accumulator Company, Chicago, is registered at the Woodstock.

B. S. Shimer, of Milton, Pa., president Star Speedometer Company, is among the visitors at the show. He is stopping at the Hotel Astor.

The Timken-Detroit Axle Company, of Detroit, Mich., is represented at the show by W. R. Timken, president; H. H. Timken, vice-president; A. R. Demory, second vice-president; E. W. Lewis, secretary and treasurer; H. W. Alden, chief engineer; F. C. Gilbert, assistant secretary; W. H. H. Hutton, Jr., purchasing agent; E. B. Lausier, assistant sales manager.

The Timken Roller Bearing Company is represented at the shows by H. H. Timken, president; W. R. Timken, vice-president and treasurer; Herman Ely, secretary; H. W. Alden, consulting engineer; R. R. Abbott, metallurgist; F. A. Miller, purchasing agent; A. G. Gladden, cashier; Herbert Vanderbeek, engineer, and F. A. Cornell, sales representative.

W. S. Gorton, secretary and general manager; C. E. Miller and H. C. Clark are at the show in the interest of the Standard Welding Company, of Cleveland, Ohio.

The Pennsylvania Tire Company, of Jeanette, Pa., is represented by C. N. Du Puy, general sales manager, and A. M. Jerome, manager.

C. F. Pratt, president and general manager of the Ohio Motor Car Company, is visiting the show in the interest of that concern.

The Mora Motor Car Company, of Newark, N. Y., is represented at the show by J. S. Draper, general sales manager; S. H. Mora, president; W. M. Freeman, treasurer; W. H. Birdsall and T. C. Colins.

Among the representatives of the Driggs-Seabury Ordnance Company, of Sharon, Pa., at the show, are C. W. Blackman, general sales manager; John Stevenson, president; H. W. Bondy and R. M. Bean.

The Gabriel Horn Manufacturing Company, of Cleveland, is represented by C. H. Foster, J. F. Gibler and H. D. Preston.

Among the representatives of the American Motor Truck Company, of Lockport, N. Y., attending the show, are E. B. Olmstead, Charles R. Bishop, Robert Hall, H. J. Babcock and R. F. Wells.

The Diamond Rubber Company has a big force at the show. Among those noticed were W. P. Miller, O. J. Woodward, J. H. Braden and S. J. Bates.

Charles Motz, president of the Motz Clincher Tire Company, of Akron, Ohio, was seen at the Palace during the week.

President August Schacht and Joseph Berle, of the Schacht Manufacturing Company, of Cincinnati, are in town during the shows.

H. S. Raymond, general sales manager and second vice-president of the Goodrich Tire Company, was also a visitor at the show this week.

Among the representatives of the Goodyear Tire Company noticed were G. M. Stadelman, W. D. Shilts, L. C. Van Beaver, F. A. Seiberling and C. W. Seiberling.

The Regal Motor Car Company, of Detroit, Mich., is represented by F. W. Haines, George W. Franklin, George D. Wilcox and E. Peake. These gentlemen are stopping at the Belmont Hotel.

J. W. Gilson, sales manager of the Mitchell Motor Car Company, Racine, Wis., one of the best known men in the trade, accompanied by J. M. Cram and E. C. Beyer, is staying at the Hotel Manhattan.

Thomas Hart, president and general manager; Fred J. Pardee, assistant manager, and L. A. Hart, who are all stopping at the Hotel Astor, are representing the Inter-State Automobile Company, of Muncie, Ind.

Fred J. Pardee, one of the best-known men in the trade, is receiving congratulations on his joining the staff of the Inter-State Automobile Company, of Muncie, Ind., as assistant to President Hart.

The Remy Electric Company, of Anderson, Ind., is well represented by W. R. Poland, G. O. Driscoll, Fred Urban and C. Herbel Morris, who are stopping at the Hotel Wolcott.

J. A. Cain and Percy Barter, of the McCord Manufacturing Company, are among those registered at the Knickerbocker.

A. R. Miller, who represents Barthol & Daly, and also the Simm's magneto, is stopping at the Knickerbocker.

W. C. Marmon and H. C. Marmon, of the Nordyke & Marmon Company, Indianapolis, Ind., are at the Knickerbocker. H. H. Rice, sales manager, and A. R. Heiskell, purchasing agent, of the same company, are at the Manhattan.

H. O. Smith, president; George Weideley, vice-president, and R. W. Macey, Jr., of the Premier Motor Manufacturing Company, of Indianapolis, Ind., are stopping at the Engineer's Club. R. I. Eads, New England manager, is at the Breslin.

V. A. Longaker, president of the American Motor Car Company, of Indianapolis, Ind., is registered at the Broztell. Fred I. Tone and C. F. Baker are at the Cadillac.

The Simplex Motor Car Company, of Mishawaka, Ind., is represented by D. A. Shaw, treasurer, and George S. Waite, sales manager, who are stopping at the Astor.

E. J. Moon and W. R. Flint, of the Moon Motor Car Company, of St. Louis, are registered at the Woodstock.

The New Grand has among its guests this week C. Van Dervoort, sales manager, and F. G. Salisbury, of the Moline Automobile Company, of Moline, Ill.

Among those registered at the Hermitage are George M. Dickson, W. G. Wall and J. M. Clarke, of the National Motor Vehicle Company, of Indianapolis, Ind.

W. H. Schwartz has resigned his position as manager of the Boston branch of the Old-Oakland Motor Company and has been appointed sales manager of the Metz Manufacturing Company, of Waltham, Mass. Mr. Schwartz was associated with the Waltham Manufacturing Company in the Orient bicycle days. For several years past Mr. Schwartz has been prominently identified with the trade. Mr. Schwartz was seen at the show, representing the C. H. Metz Company, which has a very interesting exhibit.

H. D. Van Brunt has retired from the firm of Willis & Van Brunt, of Syracuse, N. Y., and his interest has been taken over by F. S. Willis, who will hereafter conduct the business under the name of the Willis Motor Car Company, at the same address, 231 North Clinton street.

A. C. Newby, of the National Motor Vehicle Company, of Indianapolis, Ind., who has been confined to his home with a severe cold, has fully recovered and is expected at the show.

President C. A. Shaler, R. B. Dunlap, sales manager, and M. E. Faber, electrical expert of the C. A. Shaler Company, Waupun, Wis., are at the Hoffman House.

George S. Atwater, sales manager of the Tray Plate Battery Company, Binghamton, N. Y., is at the New Grand. Stanley Bayless, secretary and general manager, is at the Collingwood.

C. D. Hudson, manager of the Seeley Sales Corporation, Detroit, is at the Grand View.

Irving W. Adams, Superintendent, High Frequency Ignition Coil Company, Los Angeles, is at the Woodstock.

Charles W. Harris, General Manager of the Wayne Oil Tank & Pump Company, Ft. Wayne, Ind., is at the Knickerbocker.

President William Young, of the St. Louis Supplementary Spiral Spring Company, St. Louis, is at the Empire. Mr. Young is in town for a double purpose—to attend the shows and to prosecute suits for infringements of the famous device patented and made by his company.

President G. F. Discher, Garage Equipment Company, Milwaukee, Wis., and Sales Manager Paul G. Niehoff are at the Park Avenue. L. J. Miley and F. H. Smith, sales department, are at the Breslin.

George Schebler, of Wheeler & Schebler, Indianapolis, is at the Cumberland.

Carl J. Holdrege, sales manager, Stromberg Motor Devices Company, Chicago, and Harvey Goodwin, manager, Boston branch, are at the Cadillac.

Fred W. Smith and A. E. Sweet, of the Point Spark Plug Company, Aberdeen, S. D., are at the Cadillac.

Fred L. Holmes, manager, and Harry Matthews, purchasing agent, Jackson Automobile Company, Jackson, Mich., are at the Astor.

Elmer Apperson, of the Apperson Bros. Automobile Company, Kokomo, Ind., who has been very ill with a severe cold for the past two weeks, has gone to Florida to recuperate.

President Frank Briscoe, Sales Manager F. A. Harris and Advertising Manager J. M. Evans, of the Brush Runabout Company, Detroit, are at the Belmont.

General Manager George Kissel, of the Kissel Motor Car Company, Hartford, Wis., is at the Belmont.

W. H. Wood, of the Empire Motor Car Company, Indianapolis, Ind., visited the Palace Show Tuesday.

Charles P. Henderson, vice-president, and H. C. Lathrop, secretary, of the Henderson Motor Sales Company, Indianapolis, are at the Empire.

President J. J. Cole and C. S. Crawford, engineer, of the Cole Motor Car Company, are at the Empire.

Sales Manager H. A. Githens, G. & J. Tire Company, Indianapolis, is at the Astor, and F. A. Drake and R. W. Weiss, of the sales department, are at the Breslin.

Charles S. Monson, Western sales manager for Gray & Davis, with headquarters in Detroit, is at the Astor.

George H. Strout, sales manager, and Wallace L'Hommedieu, sales department, Apperson Bros.' Automobile Company, Kokomo, Ind., are at the Astor.

No show would be complete without Courtland D. Cramp, of the William Cramp & Sons' Ship & Engine Building Company, of Philadelphia, who is very much in evidence this week.

MAY BE GARDEN'S LAST AUTO SHOW

Historic Madison Square Garden, the scene of so many successful automobile exhibitions, must in time, it is rumored, give way to a business structure, as the property is becoming too valuable as a business centre to continue as an auditorium for the purposes for which it is now used. According to William F. Wharton, one of the board of directors of the Madison Square Garden Company, six offers have been made during the past year for the property, and the bids are receiving serious consideration. What appears to be a matter of the utmost importance is whether another similar building—so far as the ampitheatre is concerned—will be erected in New York City. Mr. Wharton, who was a prime mover in the agitation for the present Garden, says that the need of such a building is most evident, and that he would do all in his power to have another constructed provided the present one is razed, and the suggestion that the site of the present armory of the Twenty-second Regiment, Engineers, N. G. N. Y., at Sixty-eighth street and Broadway, which is available, should be taken for this public meeting place met with his hearty approval. In discussing the situation, Mr. Wharton expressed himself as follows:

"It may be next week or not until next year that Madison Square Garden passes out of the hands of the present owners," he said, "but, be the day near or distant, it is bound to come some time. The offers last year were all brought to us by agents."

STUDEBAKER AND E-M-F COMPANIES STILL FIGHTING

DETROIT, Jan. 3—Apparently there is to be no immediate cessation of hostilities on the part of the Studebaker Automobile Company in its efforts to harass the E-M-F Company pending a final settlement of the question as to whether the selling agreement formerly existing between the two companies, and which was rescinded by President Walter E. Flanders of the E-M-F Company, could thus be annulled.

After a lengthly argument before Judge Swan, in the United State Circuit Court, last Thursday, the Studebaker Company was permitted, upon its own request, to withdraw its suit against the E-M-F Company, it being made a condition of the withdrawal that in the event it was desired to begin a similar action it would be started within ten days and in the same court.

Immediately after withdrawal of the suit, Studebaker attorneys began to skirmish to secure a temporary restraining order which would again tie up the local factory. Judge Severens was once more appealed to at Kalamazoo, but as he had already gone over the facts in the case and had refused an injunction, he declined to interfere. Judge John W. Warrington, of the United States Court of Appeals at Cincinnati, was next sought, and a new bill of complaint, drafted along practically the same lines as the original, was submitted to him. He also refused to grant a restraining order, but agreed to hear an application for a temporary injunction, the hearing being set for January 10.

The bill of complaint will have to be filed in the United States District Court here, as Judge Warrington will concern himself only with hearing the application for an injunction. This will, of course, compel the E-M-F Company to put in an appearance at Cincinnati, and probably go over the same ground that was covered before Judge Severens, at Kalamazoo, the only difference being that in the present instance Messrs. Fish, Studebaker and Eames, of the Studebaker Company, appear as officials of the latter, instead of minority stockholders in the E-M-F Company.

Meantime the fight has assumed a new angle, which may result in the ousting of Messrs. Fish, Studebaker and Eames from the board of directors of the E-M-F Company. The three men have been made defendants in a suppressed suit filed in the Wayne County Circuit Court by every other stockholder in the E-M-F Company, under an old Michigan statute which gives circuit courts jurisdiction over the actions of directors in domestic corporations where bad faith and gross misconduct are charged. The bill of complaint recites details of the transactions between the E-M-F and Studebaker Companies as showing the misconduct of the trio who have been made defendants in the action. It is alleged that their refusal to take the number of cars agreed upon was in pursuance of a plan to gain control of the E-M-F Company and make it a part of an $80,000,000 merger the Studebaker Company had been fostering, a project which it endeavored to get President Flanders to entertain.

There was a stormy session of the E-M-F directors last week, the seven members of the board being present. By formal vote President Flanders' action in rescinding the agreement with the Studebaker Automobile Company was ratified, although Messrs. Fish, Studebaker and Eames protested vigorously in an endeavor to have action postponed for one week, the evident intention being to, in the meantime, see what further legal steps could be taken toward preventing a complete severance of the relations whereby the Studebaker Company was to be sole distributor of E-M-F products.

An interesting phase of the matter has come to light through the assertion of agents who have contracts with the Studebaker Automobile Company for the sale of E-M-F cars that they are being advised by the Studebakers that they had better sign up with the Detroit company for their own protection, and that they can secure the return of deposits made by them with the Studebaker Company. This action is interpreted at this end of the line as indicating that the Studebaker Company is desirous of saving itself from the possibility of litigation.

Studebaker Company Files New Bill of Complaint

DETROIT, Jan. 4—A second bill of complaint was yesterday filed by the Studebaker Automobile Company against the E-M-F Company in the United States Court, the first bill having been withdrawn.

The present bill is drafted along much the same lines as the first, the only new feature of note being a series of affidavits signed by F. S. Fish, chairman of the executive committee of the Studebaker Company, with a view to controverting certain facts in the legal battle. Mr. Fish admits that he actively tried to promote the big merger that has been hinted at, but declares that the idea was suggested to him by President Walter E. Flanders, of the E-M-F Company. In another affidavit he declares that although the schedule of August, 1909, provided for 15,200 cars to be manufactured by the E-M-F Company, for which the Studebaker Company was to be sole distributor, Hayden Eames, general manager of the Studebaker Company, had no legal right to bind the Studebaker Company to take that many cars.

The suit instituted yesterday will come up in its regular order in this district, but the application for a temporary injuction made to Judge Warrington, in Cincinnati, will be heard there January 10.

AVIATOR DELAGRANGE KILLED BY FALL

BORDEAUX, FRANCE, Jan. 4—Another name was added to the growing list of aeronautic fatalities to-day. Léon Delagrange, a pupil of Blériot, was instantly killed by a fall from a height of 65 feet when one wing of his monoplane collapsed. The machine was one of the Blériot cross-Channel type. In place of the 25-horsepower Anzani motor, which is the regular equipment, Delagrange had substituted a 50-horsepower Gnome, and it is believed that the strain of this heavy and powerful motor was responsible for the accident.

Léon Delagrange was a pioneer in aviation. Two years ago, when he was using a Voisin biplane, he and Farman were rivals, and alternated in establishing world's records for duration of flight. Last Summer he became a convert to the monoplane type, and joined the Blériot forces.

RUBBER EMPLOYEES STILL ON STRIKE

HARTFORD, CONN., Jan. 3—The strike of the tire makers of the Hartford Rubber Works Company continues. The strikers report that about 30 men are now engaged in building tires, and, of these, 13 are inspectors. This information comes from one of the strikers who returned to work and later rejoined the belligerents. The strikers still maintain pickets about the factory.

Superintendent C. B. Whittlesey has sent out, it is said, a number of circular letters to prospective help. All the men received the one day's pay due them on Monday of this week and it is said that most of the men received official notification that their services were no longer needed.

There is a persistent rumor in circulation that the company was anxious to bring about the strike and that there is some likelihood of the works removing elsewhere.

Reo Challenger Center of Interest of Winter Scene

When the Reo, driven by Ray M. Owen, made a perfect score in the New York-Atlanta run, it challenged all other perfect-score cars to a further contest calling for a detailed technical examination. None of them saw fit to accept the challenge, so this name has been adopted for that model. It will henceforth be known as the Reo Challenger.

Patent Holders Build Own Product, Now—Owing to the expiration by limitation of the license heretofore held by the Livingston Radiator Company, New York City, the manufacture and sale of Livingston radiators will be conducted in the future by the Livingston Radiator & Mfg. Co., Inc., of 312 West Fifty-second street, New York. The El-Arco Radiator Company, formerly the Livingston Radiator Company, will continue the manufacture and sale of El-Arco radiators after the first of the year 1910.

Borax King Buys a Stearns—F. M. Smith, the California Borax King, who has made "20-Mule Team Borax" famous all over the world, has recently placed an order for a six-cylinder, 90-horsepower Stearns. Mr. Smith will use this car for fast work across the California and Nevada deserts in connection with his borax enterprises. In addition to the car, Mr. Smith has given an open order for complete equipment, embracing both necessities and luxuries, that can be added to a car.

Hartford Officials' Successful Trip—H. P. Fields, vice-president of the Hartford Rubber Works Company and M. C. Stokes, manager of the bicycle tire department, have returned from a month's trip to the west coast in the interest of the company. Business is reported to be unusually good at the various agencies of the company in that section of the country. Among the varions cities visited were, Chicago, Denver, Portland, San Francisco, Seattle, and Los Angeles.

Truck Capacity Doubled—So rapidly has the 1909 allotment of trucks of the Gramm-Logan Motor Car Company, Bowling Green, O., sold, that plans for another large factory with a capacity of 1,000 truck chassis to cost $96,000 have been completed. This will be equipped with the very latest machine tools. The 1910 trucks are nearly all contracted for.

Croxton-Keeton Doing Lots of Business—For the excess business of 1910, now beginning to come in, the Croxton-Keeton Motor Company of Masillon, O., is building, and has nearly completed, a new plant at Walnut and Canal streets, that city.

IN AND ABOUT THE AGENCIES

Recent Selden Agencies—The Selden Motor Car Sales Company has been established in Kansas City, Mo., at 913 East Fifteenth street, and will be in charge of M. B. Russ. J. V. Moore has secured the local agency for Oklahoma City, Okla., and together with the Regal agency will occupy a handsome new garage. In Chicago the Selden is to be represented by the [illegible] Motor Company, the principal owners of which are T. H. [illegible] and P. D. [illegible]. The recently incorporated F. A. Ballou Company, of Buffalo, N. Y., will represent the Selden in that city. Mr. Ballou is well known in the motor-boat business.

Rauch & Lang, Minneapolis, Minn.—Announcement has been made of the organization of the Hughes Motor Car Company, which is to represent the Rauch & Lang Company in this city. The new company is planning a new garage and charging station at Harmon place and Twelfth street, to cost $20,000. Raymond L. Lunt, who will be in charge, is now at the Cleveland factory, learning the fine points of the cars. After Jan. 15 the company will also take over the St. Paul territory.

Stewart Speedometers, San Francisco—A. C. Cowan has been appointed Western sales manager of the Stewart & Clark Mfg. Co., and will establish headquarters on Golden Gate avenue, San Francisco.

Demot, Minneapolis, Minn.—Arrangements have just been concluded by which the Pagel-Allen Company acts as agent for the Demot Car.

Exide Batteries, Houston, Tex.—The Imperial Motor Car Company has just taken on the agency for Exide batteries.

PERSONAL TRADE MENTION

D. C. Fenner, formerly with the Knox Automobile Company's New York branch, is now located at the factory in Springfield, Mass., where he is concerned primarily with the commercial vehicle sales end. Mr. Fenner has been with the Knox commercial vehicle department for a nnmber of years, bnt has never found as much activity in that line as just at the present time.

George A. Horner has been appointed factory manager of the Rapid Motor Vehicle Company's plant at Pontiac, Mich., which is said to be the largest in the world devoted exclusively to commercial vehicles.

W. H. Kirkpatrick has resigned his position as sales manager of the Peerless Motor Car Company, of Cleveland, and has severed his relation with the company, taking effect January 1.

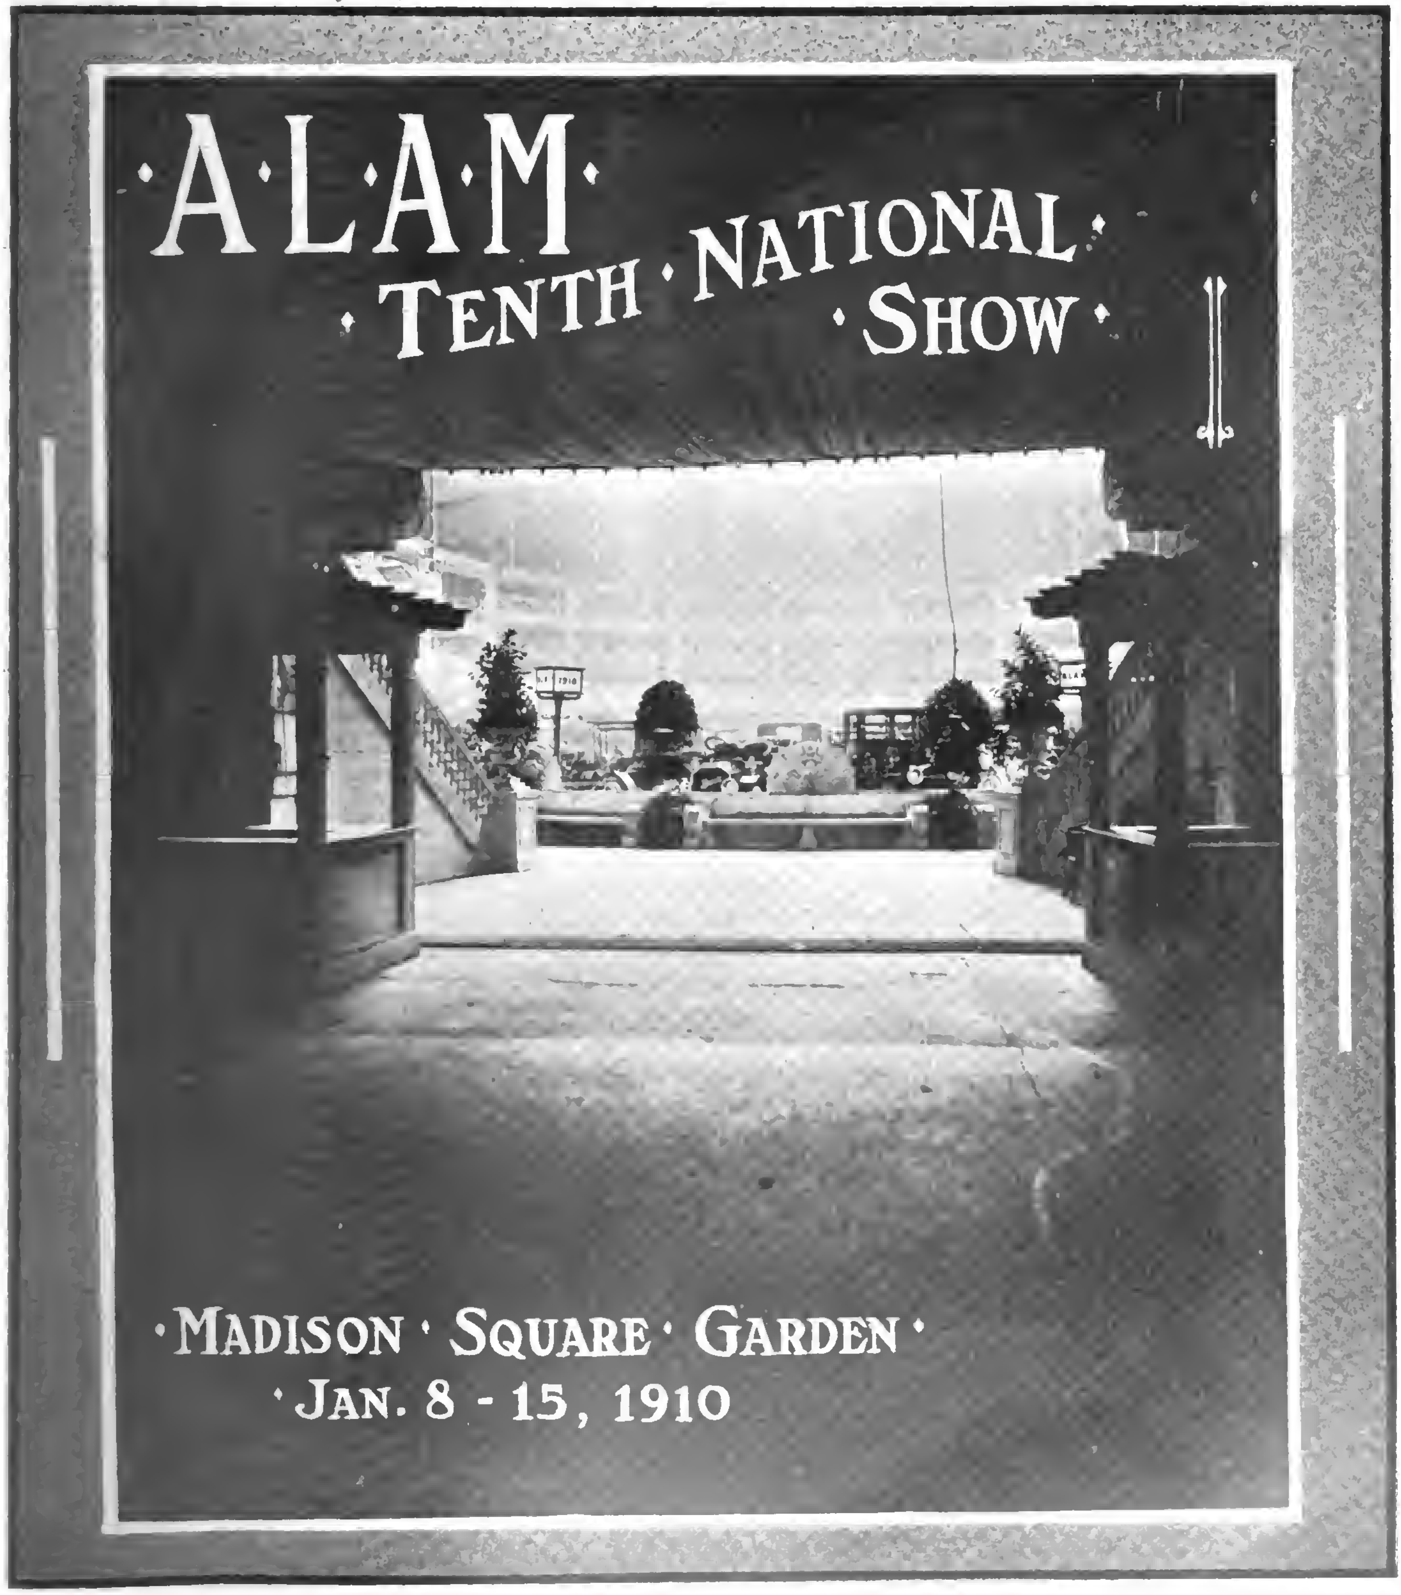
MICHELIN TIRE CO'S NEW MANAGER

MILLTOWN, N. J., Jan. 3—Following the retirement of J. C. Matlack, J. Hanvette-Michelin, a nephew of Edouard Michelin, president of the four great Michelin tire factories, has been elected vice-president and general manager, with headquarters at Milltown.

Mr. Michelin, who now takes charge of the American interests, is a man of long experience abroad, both in the manufacture and sale of tires.

Vol. XXII | New York—Thursday, January 13, 1910—Chicago | No. 2

The Automobile



Madison Square Garden Never Looked as Beautiful as It Does the Present Week, Filled with Sp

SURPASSING even the predictions and expectations of those connected with it, the Madison Square Garden show has preserved the climactic effect which has its doings. As the industry is bigger and more prosperous than it was last year, so is the show bigger and more elegant. The exhibits have been prepared with a care and thoroughness which reveals the manufacturers' appreciation of its extent and importance. Their setting is of a nature to make the Garden worthy of a visit on that score alone.

For scenic effect the Garden show seems the last word. The proportions of the building, and the broad sweep of the exhibition hall, invite a decorative treatment at once simple and magnificent. Around the walls, outlining the galleries, stand massive Doric columns in snowy white; overhead a canopy of blue bunting conceals the roof beams and gives a background to a thousand electric bulbs that twinkle like stars. Perhaps the best view of the show as a whole is obtainable from the galleries. Looking down on the closely grouped cars and the swarming crowds, it is a dull man indeed who would fail to be impressed by the vigor and wealth of this still young industry. Those with an eye to the future will inevitably speculate on the development ten years more will bring.

In many of the smaller details the care taken in preparation becomes evident. Directly opposite the main entrance stands a fountain, fronted by a curved seat. The water falls into a long, narrow basin, strewn with pond lilies and other water plants, among which goldfish dart in and out. At any time during the day the seat may be seen occupied by visitors who, tiring of the exhibits, have paused to rest and watch the throngs that stream through the wide doors.

For the first time in the history of Garden shows the boxes so famous at the Horse Show have been thrown open to visitors. These are sufficiently elevated from the main floor to give their occupants a comprehensive view of the exhibits, and have proved popular with those who come because they regard the show as one of the great society events.

The attendance, which undoubtedly will be found at the end of the week to break all previous records, has been of every character. In the morning, when the crowds are not so great, come the tradesmen and those specifically interested in the mechanical details of the cars. It is then that the salesmen are forced to exhibit their best technical knowledge. Later in the day the attendance becomes at the same time more numerous and more fashionable. In the evenings no generalizations can be made; it seems as if half the city had turned out to attend.

ducts of the American Automobile Industry, and Embellished with the Highest Type of Decorative Art

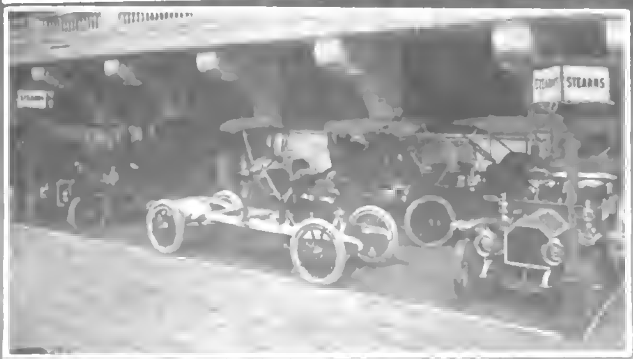
The exhibits on the whole are conservative. Half the models displayed show little, if any, change from those of last year. The most startling feature is the great number of torpedo or gunboat bodies shown. These are of every degree of radicalism. Some are only ordinary touring bodies with square doors front and rear; others run to the most extravagant curves and bulges. The manufacturers have found, however, that the torpedo body is a difficult proposition to handle, and it is doubtful if many of the models shown will be repeated very often for the benefit of prospective customers.

In its minor departments the show is up to the standard set on the main floor. Twelve manufacturers exhibit commercial vehicles, making a very complete and representative display of everything from the lightest delivery wagon to the heaviest five-ton trucks. The electric exhibit includes practically all the well-known makers of this type of automobile. Secluded from the main hall in the room known as the restaurant, it has a quiet and refinement very appropriate to the cars themselves. The accessory line includes 243 exhibitors, showing everything required to build or equip a car or to clothe its passengers.

The collection of trophies is most pretentious, and would put to blush many of the jewelry shops on Fifth avenue. A visitor can employ several hours, if he so desires, in looking them over, and if he can identify every one of them he should receive a medal for his knowledge of automobile history. Among them are the Vanderbilt, Glidden, Indiana, Massapequa, Merrimac Valley, Brighton Beach, Dewar, Sewall-Alden, Tanforan, Thermoid, Lowell, Fairmount Park, Detroit and Dead Horse Hill cups. The collection is reminiscent of many hard-fought contests on track and road. Each of them, no doubt, has contributed its mite for the information of designer, mechanic and driver, and has aroused enthusiasm in many once scornful of the new vehicle.

Once again the show committee of the Licensed Association has earned the heartiest congratulations. In the present unsettled condition of the show question, when rumors are afloat that the historic Garden is to be torn down, it is not improbable that this, the tenth annual show, will be remembered by automobilists as the last to be held in the building which witnessed the first feeble steps of the industry. Perhaps this show may mark the end of the old and the birth of a new epoch. In such case the association will have no reason to be ashamed of its most recent effort. The show is in every way worthy of the industry which it represents, and no more could be said in its praise.

SOME NOTABLE EXHIBITS AT THE GARDEN



A Glance Down the Right Hand Aisle After Entering the Garden Shows Artistic and Advantageous Arrangement

EARLY DAYS OF THE AUTOMOBILE SHOW

By COL. GEORGE POPE, Chairman Show Committee A. L. A. M.

TIME was not so long ago when the automobile was as much of a curiosity as is the aeroplane to-day. The modern motor car is no longer an invention merely to increase the pleasure of the wealthy. It has taken a place in the commercial field, and at present can be found in all its forms on the city streets and country roads. This is an age of rapid progress, and nothing better illustrates the rapidity with which developments take place than the automobile. In less than twelve years the motor car has been developed from a noisy, crude and complicated piece of machinery to its present high standard form.

It was quite an adventure to ride in an automobile only a decade ago, and it required several days of preparation for a "joy ride." The occupants of the cars garbed themselves in overalls and started out fully equipped with tools to meet emergencies, and they usually made use of their tool equipment before the "long and comfortable" ride was completed.

There are several things to which can be attributed the advancement of the motor car. Automobile shows have played an important part in the development, as have road racing and kindred contests.

The development of the industry parallels the growth of automobile shows, and an outline history of the shows will give an interesting enlightenment on the rapid strides made since the first show. At this show there were thirty-one exhibitors of cars and twenty exhibitors of accessories. There were not enough exhibits to fill the spaces, even with a board track on the main floor. Motorcycles and motor-tricycles were included with the automobiles. The track was used for gymkana events, starting, stopping and braking tests. The public was very skeptical concerning the automobiles on view, and occasionally a query was heard as to whether or not the cars would run up a hill. The first show was a financial success. The Garden was crowded at every session. The cost of putting on the first show was $11,000, not including the cost of decorations, which were paid for by the exhibitors. At this time it is interesting to glance over the complete list of the exhibitors at this early show. They were:

Elmer Motor Vehicle Co., Woods Motor Vehicle Co., American Electric Vehicle Co., Winton Motor Carriage Co., Waltham Mfg. Co., Peerless Mfg. Co., Ward Leonard Electric Co., Baker Motor Vehicle Co., American Bicycle Co., De Dion-Bouton Motorette Co., Buffalo Electric Carriage Co., National Automobile & Electric Co., Ohio Automobile Co., Autocar Co., Daimler Mfg. Co., Haynes-Apperson Co., Canda Mfg. Co., Duryea Power Co., Crest Mfg. Co., Automobile Co. of America, Knox Automobile Co., John T. Robinson & Co., Holyoke Automobile Co., Trinity Cycle Mfg. Co., Springfield Cornice Works, St. Louis Motor Carriage Co., Foster Automobile Mfg. Co., Diamond Rubber Co., Mobile Co. of America, Steam Vehicle Co., Stanley Mfg. Co., Chas. E. Miller, B. F. Goodrich Co., Dow Portable Electric Co., Locomobile Co. of America, Overman Automobile Co., Rose Mfg. Co., Goodyear Tire & Rubber Co., Janney Steinmetz & Co., New York Motor Vehicle Co., International Motor Carriage Co., Consolidated Rubber Tire Co., Badger Brass Works, C. F. Splitdorf, Veeder Mfg. Co., Gray & Davis, Strong & Rogers, Automobile Club of America, Munger Vehicle Tire Co., Beven Bros., Ware Bros., New Process Raw Hide Co., E. A. Brecher & Co., Dixon Crucible Co., Downing & Co., Gleason Peters Air Pump Co., New York Belting & Packing Co.

The second national show was held in the Garden during the week of Nov. 2-9, 1901. There were ninety-three exhibitors in this. The track was omitted, and again there was a loan exhibit of foreign cars. Among them was a Darracq, a Napier, a Renault, a Mercedes, and a Mors shown by Foxhall P. Keene.

About this time the industry began to develop, and with an increasing output by the factories the makers found it necessary to act as wholesalers only. It was during the year of 1902 that the commercial future of American cars became more certain. The National Association of Automobile Manufacturers was organized, and it was decided after several conferences that the next show would be held at the beginning of the year instead of at the close, and it should be managed by a committee, on which the N. A. A. M., the Automobile Club of America—under whose auspices the first show was held—and the Garden company should each be represented, and it was arranged that these organizations should share in the profits.

There was no show in 1902, and the third one was held in the Garden during the week of January 17-24, 1903. The number of exhibitors had now grown to more than 150, and for the first time a foreign exhibitor took space; this was the Paris Automobile Company, represented by H. Fournier.

The fourth national automobile show was held at Madison Square Garden on Jan. 16-23, 1904. This show had more than 185 exhibitors, and was held under the same auspices as the previous one.

The automobile industry was growing so rapidly that at the fifth show in the Garden, January 14-21, 1905, many firms seeking space had to be refused. The show was held under the same auspices as before, and 250 exhibitors secured space.

With the 1905 show, the contract between the National Association of Automobile Manufacturers, the Automobile Club of America and the Madison Square Garden Company, expired, and the Association of Licensed Automobile Manufacturers obtained a lease of the Garden for several years, with an option of renewing it.

When the show passed to the auspices of the Association of Licensed Automobile Manufacturers, a committee was appointed to take charge of the whole affair. Up to that time the individual exhibitors were permitted to decorate their booths as they pleased, and the general result was a mess of bunting, irregular and glaring signs, and there was a confusion of color to be seen everywhere about the Garden. The show committee took charge of the decorating and, in fact, everything connected with the show management. They formulated plans to make a harmonious exhibition, and the decorating was placed in charge of an expert. Thereafter the signs of the exhibitors were made of uniform size, color and design. Other details were carried out to conform with the ideas of the show committee.

The sixth annual automobile show was held in the Garden, Jan. 13-20, 1906, under the auspices and management of the A. L. A. M. There were 50 exhibitors of cars and 170 exhibitors of parts and sundries.

Under the same auspices as its predecessor, the seventh annual show was held in the Garden during the week of Jan. 12-20, 1907. That the public was now deeply interested in automobiles was strongly emphasized by the vast number of people who attended the show on the opening night. More than 7,000 people were there. At this show there were 42 exhibits of cars and 202 accessory exhibits. There was another show that same year. It was held in Madison Square Garden during the week of Nov. 3-10, 1907. This was the eighth national automobile show under the auspices of the A. L. A. M. There were 68 exhibits of complete cars, a number of commercial vehicles and about 225 accessory exhibits.

The ninth national automobile show under the auspices of the A. L. A. M. was held in Madison Square Garden, Jan. 16-24, 1909. At this show there were 117 complete cars, 28 chasses, 37 electric vehicles and a number of commercial vehicles.

The number of exhibitors at the present show in the Garden, the tenth national, indicates in a great measure how wonderful has been the growth of the automobile industry in America. Even with an increase over last year of many thousands of square feet of floor space for exhibition purposes, many would-be exhibitors could not be accommodated. The list of exhibitors shows that there are 323 different displays, of which 54 are exhibits of complete cars, 23 are motor-cycle displays, and 240 are exhibits of accessories and parts. It can be safely said that the present show is bigger and better than its predecessors.

Torpedo Types Representative of the Most Advanced of Comfort-Creating Designs of the Year

Lighting by Latest Electric Methods

By Thos. J. Fay

Fig. 1—Pierce-Arrow limousine of artistic design with electric lighting on the same basis

MERIT, like the mill of the gods, is sure, but, unlike the great contrivance, it is not, of necessity, slow. This same merit, as it resides in electric lighting as applied to automobiles, seems to have copied the first characteristic of the mills of the gods, for its development has not maintained pace with the well-authenticated qualities of [illegible] lighting as it is generally applied. The retarded growth [illegible] branch of the industry was not due, at any time, to the [illegible] of desirable qualities in electric light, nor can it be conclusively shown that the discovery of the tungsten lamp is to account for the present activity.

At all events, electric lighting to all appearances is now with us to stay. Tungsten lamps will have an important part, storage batteries will also be in proper presence, but it is in the source of electricity that the present activity is centered.

[illegible]ROVEMENTS MADE IN METHODS OF DRIVING DYNAMOS

[illegible]mos, as they are used in conjunction with storage bat-[illegible] (if they have to do charging work), are as a rule shunt [illegible] meaning that the coils of wire (insulated), which are [illegible] around the fields for the purpose of exciting them, are in [illegible] with the armature windings, and this parallel relation [illegible] other advantages, the property of fixing the rotation [illegible]mature in one direction only, whether or not current [illegible] the dynamo (thus making it a motor), or leaving the [illegible] when the machine is performing its proper function as a [illegible]electric machine.

[illegible] shunt wound machine, if the speed and load is constant, [illegible]ge at the brush terminals will be constant also; if the [illegible]anges, however, the voltage will change also, and if the [illegible]anges, so will the voltage, due to what is designated as [illegible] "drop," which is due to I^2R losses, for the most part, [illegible] partly to heat increase, due to increasing load.

Constant Speed Required in Lighting—If lighting is to be [illegible] direct from a shunt wound dynamo it is necessary to run [illegible] at a constant speed, and if the load changes, then the [illegible]ance, as measured in ohms, of the field, must be adjusted to suit the altered conditions. A compound wound dynamo could be used (is used in general lighting work) were the speed constant, and with changing loads; this type of winding differs from shunt windings, due to the presence of a second winding on the fields, which supplementary winding is in series with the armature, so that the output of the armature passes around the fields, and they are strengthened in proportion as the armature reaction tends to weaken them. Moreover, I^2R drop, in the armature as well as in the series winding of the compounded field, is compensated for, in fine, by over-compounding, which is but a matter of adding a few extra series turns to the field windings. It is possible to compensate also for line losses outside.

All these devices so well known to the electrical engineer are put to naught by the changing speed which obtains in a gasoline motor as it is used for its conventional purpose, and, to add to the confusion, the motor is likely to be stopped betimes, perhaps to make an adjustment, perchance by night, and lights will then be in excellent demand. A tail light, for illustration, should not be allowed to go out, especially when a car is standing still by the roadside on a dark night, and electric lighting, to be a good success, must be capable of doing its work at all times.

Under plain conditions, then, electric lighting direct from a dynamo cannot be done if the power is taken (to drive the dynamo) from the motor which is placed to propel the automobile, for the very simple reason, as before intimated, that the motor is required to run at a variable speed, and the dynamo requires a constant speed. True, there is such a scheme as a "differential compounding," it having the facility, within limits, of rendering the characteristic of the dynamo that of a constant voltage machine under a variable condition of speed. Unfortunately, as it seems, the range of this type of machine is very limited, and it will be remembered that automobile motors change in speed over a broad range; possibly as much as 10:1.

Obviously it would be an extremely difficult task to so design a dynamo that the differential compounding would work satisfactorily under such wide conditions of speed change, nor has any designer ever succeeded in accomplishing this to extent, although, in connection with wind-motors (which run at a variable speed), some success was attained, and for a time it looked as if the task might be fulfilled within certain limits.

Special Forms of Windings Abandoned—The struggles for success through special windings on the dynamos used were long ago abandoned, and for a time it looked as if electric lighting would have to be accomplished through the use of storage batteries unaided by any automatic charging means at hand, which idea, from evidences afforded, seems not to have appealed to autoists, and as a result acetylene lighting was relied upon for the most part. The storage battery unaided, as will be readily appreciated, would have to be of large capacity, or it would be necessary to remove and recharge the same at frequent intervals. This might not be a task of great difficulty were all cars maintained in garages equipped for the work of charging storage batteries, but such is not the case, and, to care for the great majority of automobiles, it has been necessary to fit out with acetylene lighting equipment.

What This System Comprises—Referring to (A) Fig. 2, and to C in the figure, which is a camera, it will be noted that the same is focused on a dynamo D in the figure, and the photograph was taken utilizing the actinic rays, which emanated from the searchlight L just below and to one side of the camera. This illustration indicates that the light is of high intensity, and the dynamo, which is about to be described, was driven in this case by an electric motor for the obvious purpose of illustrating its capability under speed changing conditions.

The electric motor placed and connected with the dynamo was of the shunt wound variety, and a rheostat was utilized for the purpose of varying the speed of the motor, in order to approximate the conditions which exist when the lighting dynamo is connected with a gasoline motor as it is used on an automobile. This is done with a view of having the lighting dynamo run at a constant speed, notwithstanding speed variations over a wide range of the automobile motor.

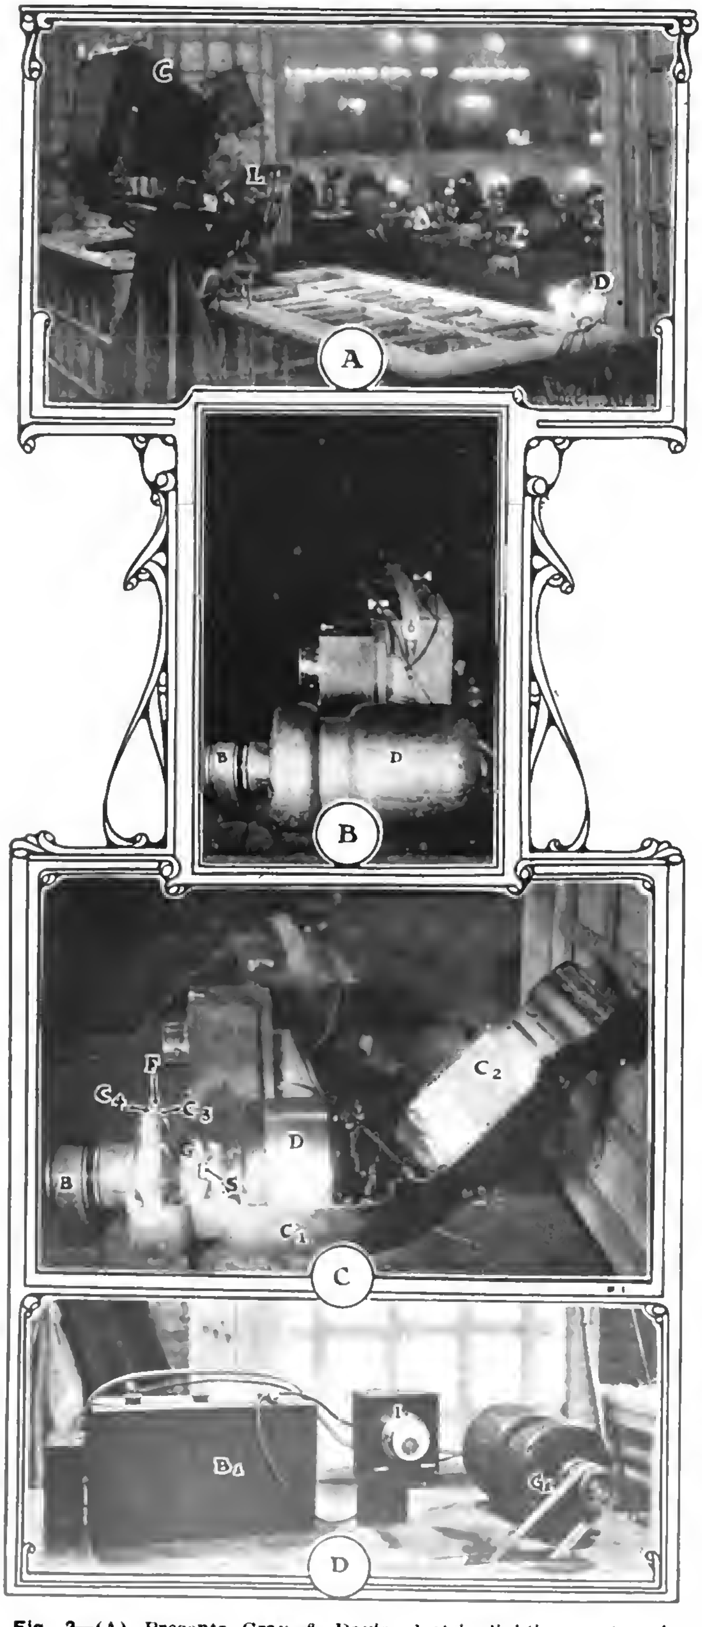

Fig. 2—(A) Presents Gray & Davis electric lighting system in operation aiding the camera
(B) Shows the exterior of the generator offering evidence of adequate protection
(C) Portrays the generator with the cover off and a view of the governor and speed regulating mechanism
(D) Depicts the Exide battery and measuring instrument

In order to indicate the compactness of the lighting dynamo, B, Fig. 2, is offered in which D is the dynamo, showing the exterior, and how thoroughly it is enclosed, while B is the belt running over a pulley, which also connects over a driving pulley, placed at some convenient point on a driving member of the automobile motor. The power which comes from the automobile motor is subject to wide speed variations, and these variations are transmitted along the belt B, thence to the dynamo pulley and shaft which protrude out through the shell D of the dynamo.

In order to appreciate the operation of the dynamo, it will be necessary to examine the interior, for which purpose (C) Fig. 2 is presented, in which C1 is the base half of the protecting shell, C2 is the detachable half of the same, D presents the dynamo, which connects its armature shaft with the shaft protruding through the case to the pulley, over which the belt B runs. In order to be able to vary the speed of the driving member (the automobile motor) without suffering speed changes of the armature of the dynamo D, a governor G, under the influence of centrifugal force modified by the pressure of the spring S, is then utilized to excellent advantage.

The speed changes, or rather a constant speed of the dynamo armature results from slipping on the clutch faces, F, by variations in pressure on the clutch members C4, brought about through movement of the clutch members C3, under the influence of the centrifugal (weighted) governor G, in view of the action of the spring S. The facing F, is asbestos fabric, and the area of the transmitting surface is so regulated that the speed of the dynamo is maintained at 1,200 revolutions per minute, irrespective of speed changes within all possible limits of automobiles under road conditions of performance.

The pressure of the transmitting faces of the friction members is but slight, it being the case that the output of the dynamo is 60 watts, which is not so very great, in view of the fact that there are 746 watts in one horsepower. It required a good deal of experimenting to arrive at the correct proportions of the governor weights G, and the proper resistance offered by the opposing spring S. The performance will be obvious from what has been said, considering the clearness of the view C, Fig. 2. It simply follows that one of the clutch members is sleeved, which permits axlewise motion, but the load on the dynamo being nearly constant, in view of the use of a storage battery, permits of designing the governor so that the slippage on the disc faces will be in conformity with the requirements.

A SPECIAL EXIDE BATTERY IS USED

Referring to (D) Fig. 2, G1 is the dynamo, looking at the pulley end I1 represents the measuring instrument which is used to ascertain the potential difference in volts across the terminals of the battery and the same instrument, by suitably manipulating, tells the output of the dynamo or battery in amperes. The battery is shown as B1, there being three cells within a suitably contrived hard-wood case.

The battery has been especially designed with a view to compactness, relatively light weight, and high watt efficiency. The life is guaranteed for three years under the conditions of operation as fixed in this system. This long life comes primarily through the adaptation of a special and particularly well-built battery, but the fact that it is "floated" on the circuit influences the life situation very materially.

This system of lighting affords the widest range of service, eliminates all other forms of illumination when it is used, because the battery has ample capacity to furnish current to tungsten lamps for head and side lights, as well as a tail lamp, for several hours, if the occasion requires, so that if the automobile motor is shut down for any reason, the lighting goes on without diminution of intensity, which condition would obtain for many hours, even under the most unfavorable conditions.

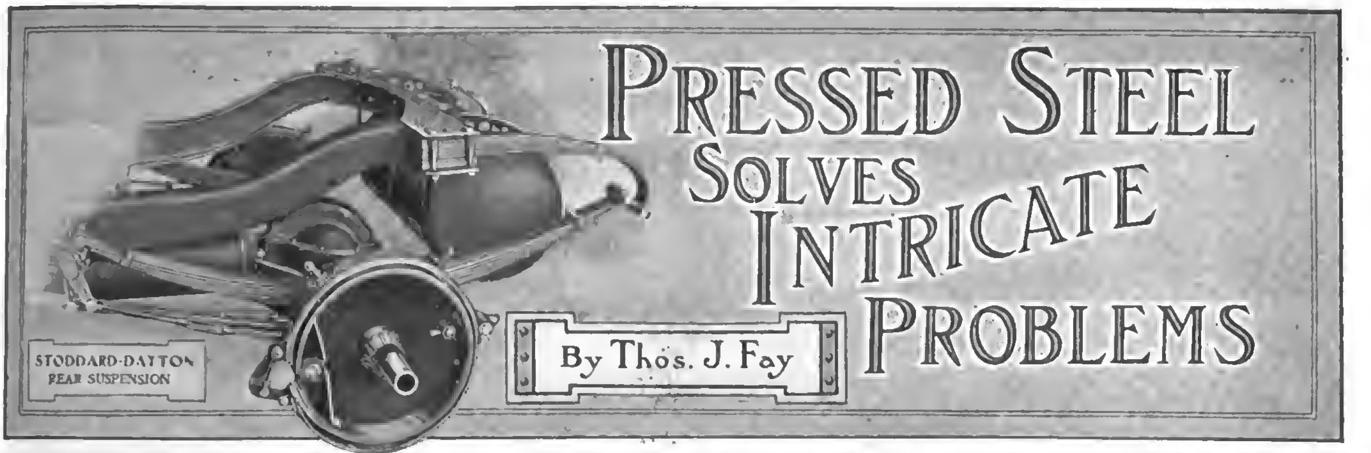

Fig. 1—Rear suspension of Stoddard-Dayton cars with 3-4 elliptic springs, and a shackle bar system of holding

FABRICATED materials differ from castings in important particulars, and while quality of material, that is to say, its chemical composition, is important, even so the extent of fabrication must be taken note of when an attempt is made to take an inventory of quality.

The difference between fabricated steel and steel castings is represented by the amount of work done upon the castings in rolling or forging. Direct steel castings are made by charging crucible pots, or Bessemer furnaces, and when the charge is brought up to the proper heat it is first poured into ladles and then transferred to moulds, the moulds being substantially the same as those used in gray iron foundries.

In the production of fabricated steel the ingots are first produced and they, after being suitably manipulated, are rolled or forged into the desired shapes. It will not be the purpose here to delve into the processes employed in the production of steel, but the above will be enough to show that, as before stated, the difference between a casting and fabricated steel is represented in the amount of work done upon the steel after casting.

If, in working or fabricating steel, it may be improved, which is true, it follows that shapes, as they are employed for different purposes, will have different qualities. This point is adequately brought out in connection with T-rails. When these were of light weight, varying from 40 to 60 pounds per yard, photo-micrograms showed a certain structural condition, which indicated the excellence of kinetic qualities, and the rails proved to be of great longevity in service. As rails were increased in weight, breakages were more frequently noted, and to-day, with rails ranging from 90 to 110 pounds per yard in weight, this question of breakage assumes the proportions of a paramount issue.

It is claimed by the steel makers that there was no substantial difference in the quality of material used, and nearly all rails were produced by the Bessemer process. The differences were directly traced to ills of fabrication, it being true that the heavier weight rails are not subjected to the same amount of work as that which was put upon the lighter sections in former times.

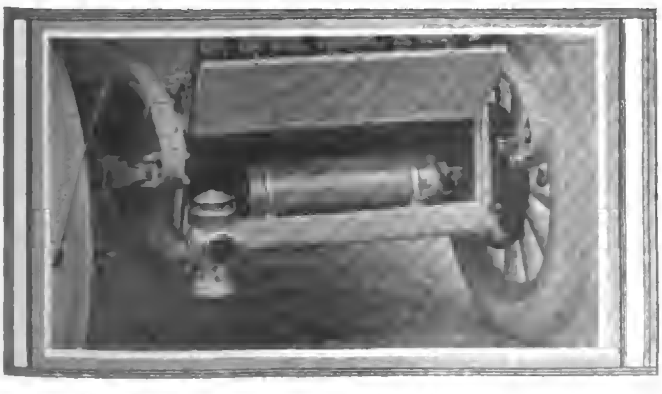

Fig. 2—Rear suspension of Pierce-Arrow cars with 3-4 elliptic scroll springs, flush with the side bars

Structural steel of the various shapes has proven to be of exceeding value, and much of this ability is due to the amount of work which must be put upon the material to reduce it to plate form. Quality of material, as it is reflected by chemical composition, is of moment, but it is not the whole story.

In kinetic work, the life of the steel, according to the best authority, seems to depend:

(A) Upon the carbon content;
(B) The carbon condition;
(C) The extent of metalloids;
(D) Ratio of other contents;
(E) Process;
(F) Method of fabricating;
(G) Extent of fabricating.

Taking (A), which is a carbon content, Harboard, after making many experiments, proved conclusively that the shock-resisting qualities decreased with increasing carbon. As to (B), which refers to the carbon condition, there is everything to be gained by resolving the same into the best form, considering the service to be rendered, so that heat treatment becomes of the first importance. (C) considering metalloids, as sulphur and phosphorus, they must be very closely held, particularly in flat steel, and it would not be too much to expect that these elements will come within 0.030, but this must not be construed as a license to reduce metalloids by the utilization of a basic process.

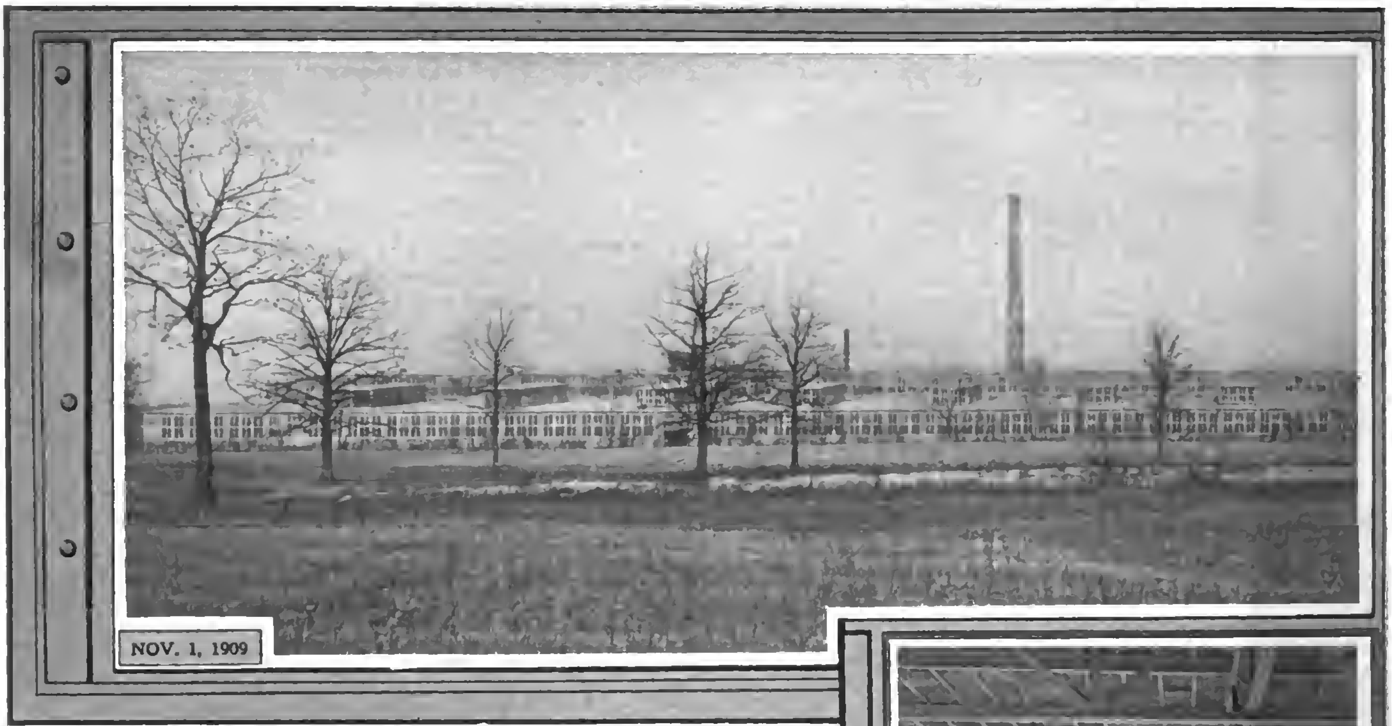
Harboard showed, among other things, that steel by the basic process, will not sustain under shock condition to nearly the same extent as will acid steel. Taking the metalloids by chemical analysis then, is not conclusive evidence of quality from this point of view, because the metalloids may be the same in inferior as in superior steel, depending only upon the process employed. (D) refers to manganese and silicon, assuming that copper and arsenic are but a mere trace.

The manganese and silicon contents will differ from the respective products, partly due to process, and, to some extent, with carbon, presence of metalloids, and alloy in elements. It will not be feasible then to discuss the presence of these elements more than to point out that they are suitably regulated under the several conditions of manufacture.

ALLOY STEEL LOW IN CARBON

The presence of chromium nickel, vanadium, tungsten, or other alloying elements, does not seem to alter the main fact, i. e., that carbon must be closely held. Experience in connection with the utilization of alloy steel is relatively limited, and the automobile has been at the bottom of this activity, more perhaps than the influence of any other art, not forgetting that armor plate and projectiles were previously (and are now) alloy steel products. There is a considerable difference between the alloy structural steel as used in automobiles and the material which obtains in the production of armor plate and projectiles.

The very difference between the composition of a projectile



and that of an alloy steel-side frame, as used in automobiles, will best illustrate one of the points to be here made. The projectile must be intensely hard, and yet it is expected to disrupt into fragments at the propitious time. The automobile side frame must be strong, but it is not expected to fracture if it is subjected to a load greater than it can sustain. The projectile is high in carbon, and if it is a chrome product, it will be very high in chromium also. The automobile frame will be very low in carbon, and if chromium is present, it too will be relatively low.

KINETIC ABILITY IS SOUGHT AFTER

In pressed steel work, as it obtains in the automobile zone of activity, every effort is made to induce kinetic qualities and to bring the elastic limit of the material as near to the tensile strength as possible without depressing elongation, as it is measured in a given length, say, eight inches in flat plates. The behavior of the material has to be considered as it relates to heating, drawing, pressing, or otherwise forming, and if the steel is to be worked up whole, it must have qualities to correspond, whereas, if it is to be worked under high heat this question must be taken into account as well. The quality of any piece of steel may be initially good and be ruined, in heating, due to a mal-temperature.

A considerable percentage of material, as it is used in automobiles, is probably in accord with the A. L. A. M. specifications, which, for side frames, may be stated as follows, on the opposite page:

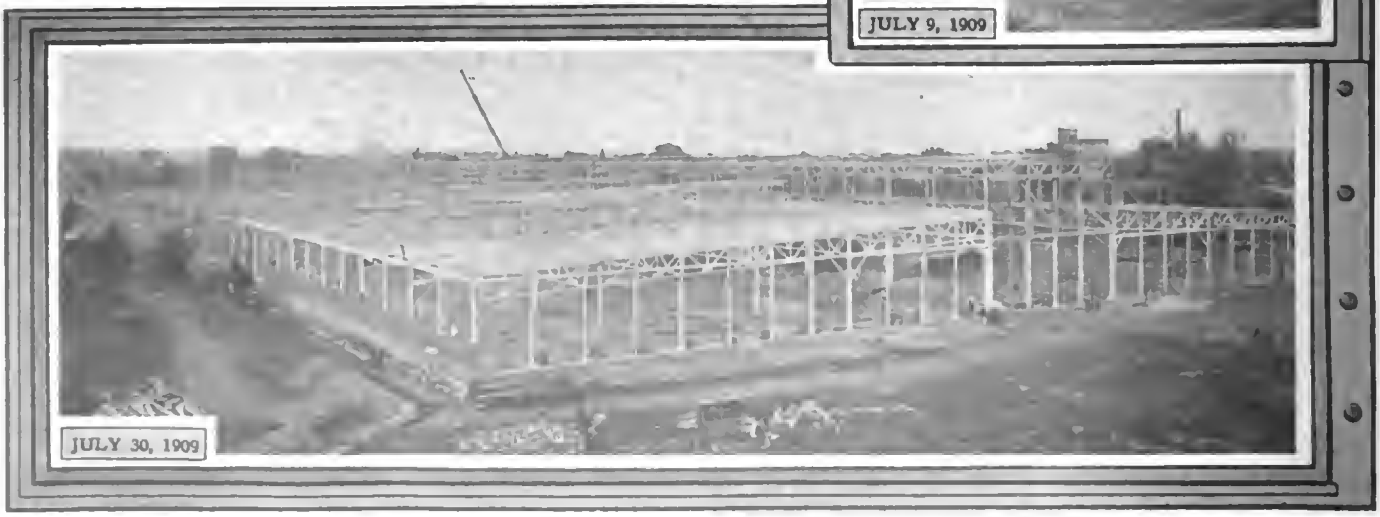


Fig. 3—New A. O. Smith plant, at Milwaukee, Wis., devoted to the

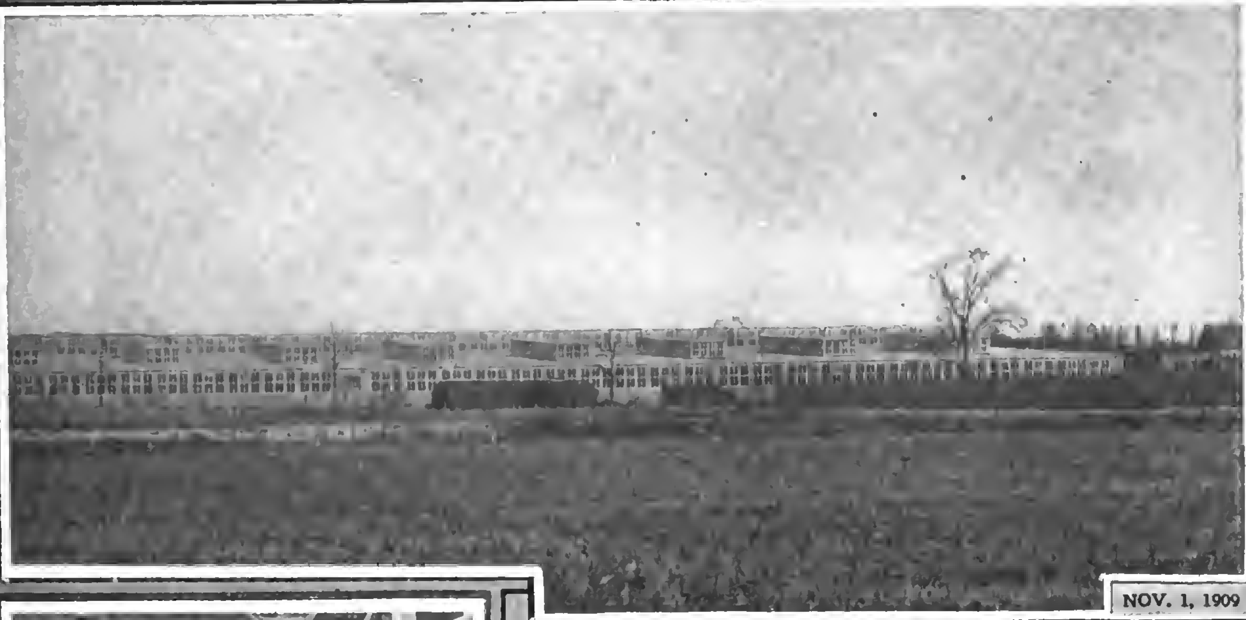

NOV. 1, 1909

NOV. 5, 1909

ALLOY STEEL FOR PRESSED FRAMES

Chemical Composition

Chromium, 0.50 to 1.00.
Nickel, 1.50 to 2.00.
Carbon, 0.20 to 0.30.
Manganese, 0.40 to 0.60.
Sulphur, 0.04 maximum.
Phosphorus, 0.04 maximum.

Physical Properties

Tensile strength in pounds per square inch, 80,000.
Elastic limit in pounds per square inch, 45,000.
Elongation per cent. in two inches, 20.
Reduction of area per cent, 40.
Physical condition, annealed.

The same steel, when subjected to the treating process, will perform as follows:

Physical Properties

Tensile strength in pounds per square inch, 150,000.
Elastic limit in pounds per square inch, 100,000.
Elongation per cent. in two inches, 8.
Reduction of area, per cent., 35.

Frames of this material are hot pressed, and in the heat treating process are first quenched in oil, after which they are partly annealed, the idea being

NOV. 19, 1909

NOV. 15, 1909

production of pressed steel, transmissions, steering gear, etc.

Fig. 4—Pressed steel brake drum, as used on the Cole 30, with a flat steel band in constricting relation

to fetch up the elongation to the point as given, as a minimum value. If the quality of the steel is up to specifications, physically and chemically, when in the annealed state, it should perform as noted when it is properly heat treated.

Many of the best examples of chassis frames, as they occur in automobiles, are made of this class of material, and here the strength is adequate for every possible need, although it has been found that the use of material of this character does not warrant diminishing the weight of the section employed, because it has not been shown that chassis frames of the customary channel section and weight per unit length, when made of Bessemer plate, were sufficiently strong to serve under certain conditions. The introduction of alloy steel, then, was not for the purpose of reducing weight, but it was with the intention of bringing up the strength to meet the most severe requirement. This view is not generally well understood.

SILICO-MANGANESE STEEL FOR FRAMES

Chemical Composition

Carbon, 25 to 35 points.
Manganese, 1.50 to 2.00.
Silicon, 0.75 to 1.00.
Sulphur, 0.035 maximum.
Phosphorus, 0.035 maximum.

Physical Properties

Tensile strength in pounds per square inch, 120,000.
Elastic limit in pounds per square inch, 80,000.
Elongation, per cent., in two inches, 15.
Reduction of area in per cent., 40.
Condition of test proof, annealed.

This steel, when quenched in oil and partly annealed, should test as follows:

Physical Properties

Tensile strength in pounds per square inch, 160,000.
Elastic limit in pounds per square inch, 120,000.
Elongation, per cent., in two inches, 10.
Reduction of area in per cent., 30.

This steel as a type is much used in chassis frames and is frequently employed for springs. In the frame stock as it comes from abroad the carbon is somewhat lower, possibly 10 points, and the silicon is frequently considerably lower, whereas the manganese is held at about 1.60. At all events, this material ranks relatively high and many automobile engineers prefer it to the alloy steel or side frames as hereinbefore mentioned.

TYPES OF CARBON STEEL MUCH USED

Cold-pressed side and lateral members are generally of carbon steel, and generally the carbon content in this type of steel, for this class of work, runs well below 20 points, and 10 points carbon seems to be the prevailing limit. In some of the very excellent examples of carbon steel-side frames government specification boiler plate is used, and experience rather goes to show that this material, when used in sufficient presence, is entirely satisfactory for the purpose.

Government specification boiler plate, besides having carbon approximating 8 points, is an acid open-hearth product, with sulphur and phosphorus below .04, with well-regulated silicon and manganese. The tensile strength is not remarkably high, but the elastic limit approximates 55,000 pounds per square inch, and the elongation, in 8 inches, is better than 24 per cent. A specimen of this steel will bend over and flatten down to 180 degrees without showing any sign of fracture, and a silky structure exists.

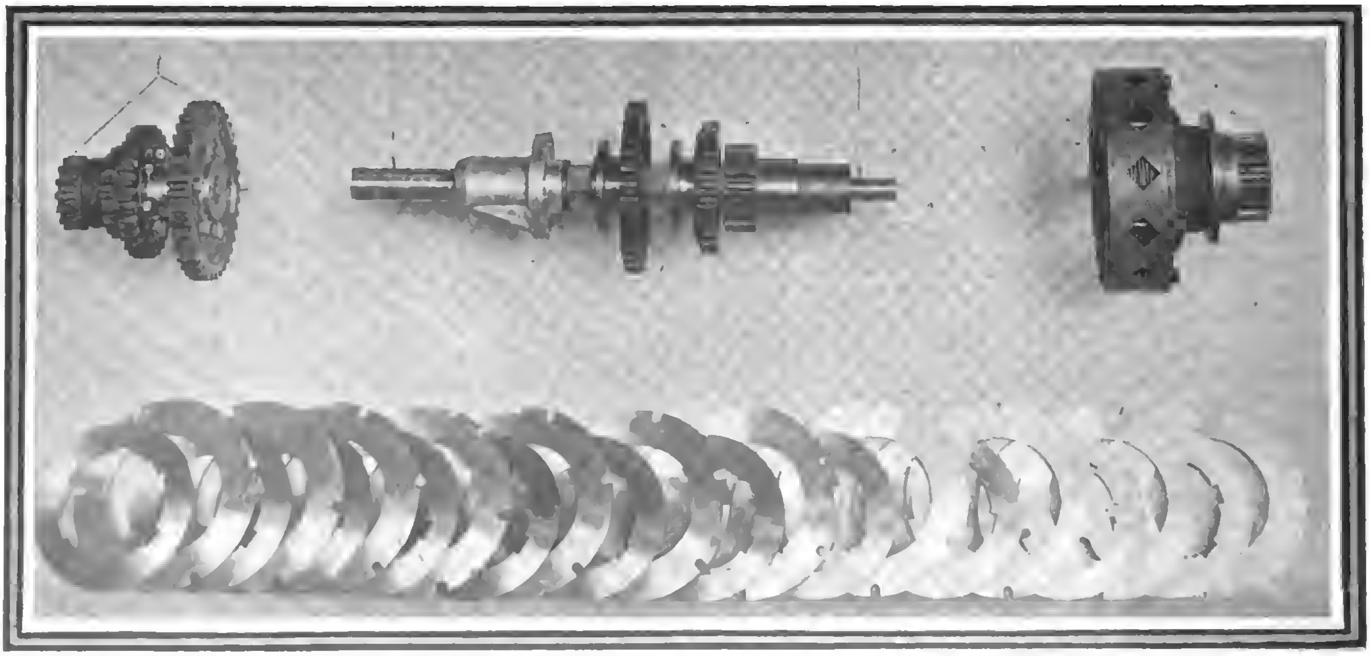

Fig. 5—Discs of stamped steel, as used in the clutch of the unit power plant in Demotcars

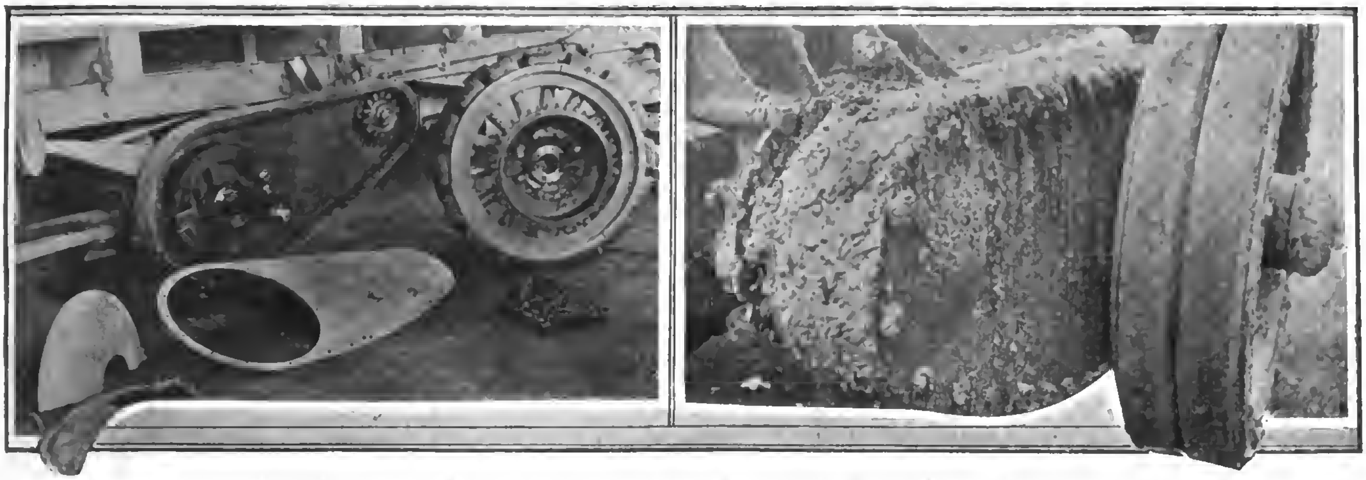

Fig. 6—Pressed steel chain boot, dissembled and in service, as used on Alden-Sampson trucks

In some of the earlier efforts Bessemer plate of a very ordinary grade was cold pressed into side and cross members, and frequently fracture was brought about by a 90-degree bend at a 3-8-inch radius of a 3-16 thickness of plate. This class of material failed in service, and frequently the failures were disastrous. It was probably the original basis for a considerable effort in the direction of universal joints, inasmuch that in the earlier types of automobiles, the respective units were mounted upon the chassis frame and an attempt was made to join these units into power relation without introducing flexible members.

Chassis frames of this character deflected under the load and the rigid relations of the units, which made up the power and transmission system, led to early trouble in the life of these cars in service. Designers desiring to get away from this trouble formed the habit of introducing universal joints, but in the meantime the incentive was there for improvements in chassis frame work, and in the long run it was found that no chassis frame, however made, could be regarded as sufficiently rigid to serve as a machinery platform with several machinery units in rigid relation.

UNIVERSAL JOINTS DESIRABLE IN ANY EVENT

The later introduction of special grades of steel in the chassis members eliminated troubles in the chassis itself, but tests soon showed that there was a certain amount of deflection under stress, due to road conditions and to the very flexibility which was courted by the utilization of fine grades of material. Under the circumstances it was found desirable to retain universal joints, the principle of the three-point suspension, and all the other methods which would permit the machinery units to operate with freedom, despite deformations due to shock brought about by high speed and considerable road undulations.

Excepting for a few examples of wood chassis frames, as in the Franklin (which is laminated) and in the Brush, not forgetting the armor type of wooden frame as used in the Panhard-Levassor, chassis members are almost invariably of the channel section and relatively deep, involving the flanging. Considering channel sections, there are classifications as follows:

(A) Straight side members.
(B) Narrowed in front.
(C) With a rear kick-up.
(D) With a rear kick-up narrowed in front.
(E) Underslung.
(F) Underslung narrowed in front.
(G) The several types with subframes.

Straight side members (A) were formerly much in vogue, but owing to the increase in diameter and sections of tires which are now used, it is extremely difficult to realize a sufficient canting angle of the steering road wheels, without having the chassis members closed in considerably more than usual.

With side frames, which are straight on the top edge, they are frequently narrowed (B), in order to afford an adequate canting angle of the road wheels, and in such frames with a view to offsetting the weakening effect at the narrowing point, the flanges are made somewhat wider and crossarms are placed to support the cranking moment.

Frames (C) with a rear kick-up (drop frames) are so made in order to bring the running board on a line with the curb and to have the height of the step from the running board to the side entrance that which is convenient. It is also claimed that the center of gravity is lower in these types of cars, but it is highly improbable that the difference is very great, because the power plant and transmission system will be a distance from the ground which is dictated by the diameter of the flywheel, considering the desired road clearance. To illustrate this point, it is only necessary to say that the axis of rotation of the power members will be 18 inches from the ground if a 16-inch diameter flywheel is used, and if the road clearance is 10 inches. This clearance requirement, considering the diameter of the flywheel as used in any given case, comes very near to fixing the center of gravity independently of the type of chassis frame employed. The condition (D), which calls for a narrowing at the front-side frame with a kick-up in the rear, obtains in nearly every case, although there are one or two examples to the contrary.

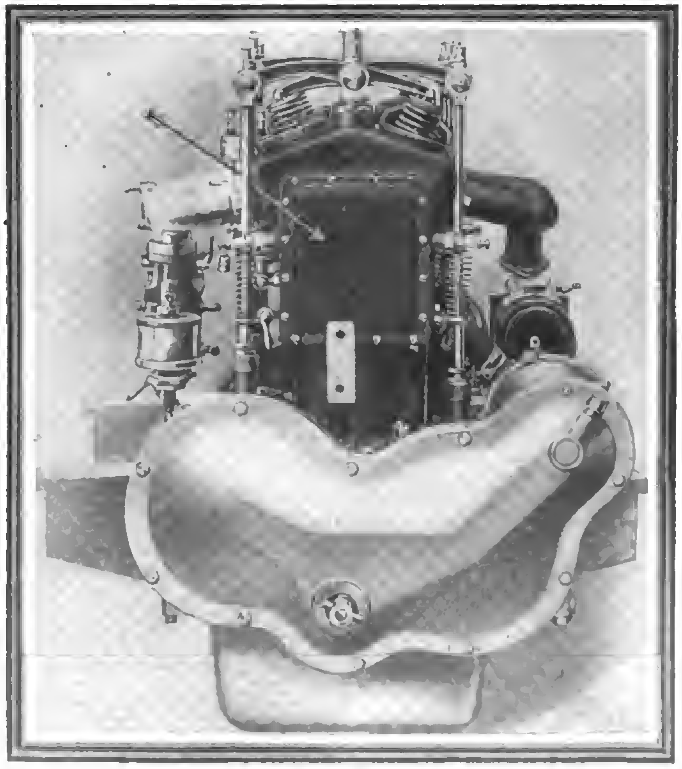

Fig. 7—Stoddard-Dayton motor, with pressed steel covers over the openings of the cylinder water jackets

Underslung frames (F) are narrowed in front, and, as utilized in connection with American cars, such as the American Tourist and other types by the same makers, take into account the use of large diameter road wheels, thus permitting the chassis frame to pass below the axle and allowing of ample vertical clearance besides the necessary ground clearance. So it is that the general appearance and performance of these cars is commendable. This type of frame was originally brought out for racing work and, barring the influence of a body, it induces a lower center of gravity, while the large diameter road wheels makes for easy riding qualities.

Subframes (G) are used in a considerable number of examples and it has always been claimed by a certain school of designers that it is a particular advantage to place the machinery equipment on its own independent subframe. The length (span) of the motor support arms is considerably reduced when the subframe is employed, and, since the arms are almost invariably of cast aluminum, it is claimed to be an advantage to have them relatively short. Since the subframe does not have to interpret the stresses, which play on the side frames through the springs, there is just a chance that this same subframe acts as a more stable machinery platfrom than does the side frame.

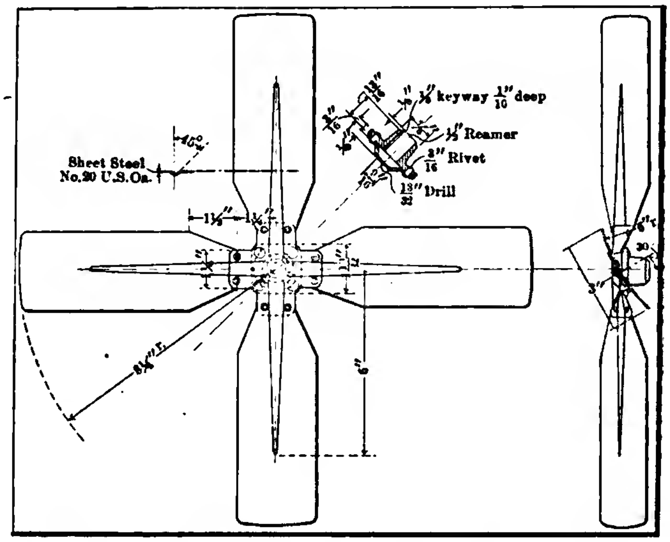

Fig. 8—Premier fan, with four blades of pressed steel, ribbed and beaded for strength

IN THE MANUFACTURE OF CHASSIS FRAMES

Work of this character is now conducted in a large way in plants especially fitted out for the purpose, and special heats of steel of a required composition for each type of material are ordered in such vast quantities that quality is very readily obtained on a basis of proven quality.

The material comes to the pressed steel mills in flat sheets of the required thickness, specified as to width, and sufficient in length to turn out the members to be made with very little waste, frequently without any trimming at all. If the work is to be done cold, which is a matter depending upon shape and the quality of the material to be used, the sheets are cut to approximately the right area, and through the use of suitably formed dies, which are fixed in the presses, the sheets are pressed into the required shape, generally in one operation, although some of the intricate cross-member sheets have to go through two or three operations and in many cases hot.

If the material is alloy steel, either with chromium nickel or vanadium, the work must be done hot, in which event the sheets, after they are trimmed to the right size, are brought up to the desired heat in a furnace and then passed to the dies in the press when the final operation of pressing is conducted—generally in a single operation. From the press the members go to the heat treatment room where they are raised to a correcting temperature, then quenched in oil, and subsequently annealed in order to increase the elongation and bring up the other physical properties to conform to the original specifications, unless, under conditions of great skill, better results are evolved.

When the work is done cold, as it is with carbon steel, instead of oil quenching and annealing, the members are corrected by a simple annealing process, excepting in the cases of superior grades of specification carbon steel.

When the side bars and cross members are heat treated or otherwise completed in the absence of a heat-treated operation, they are then trimmed and put into final shape for assembling, which includes making the holes for rivets in some one of the ways as follows:

(A) Punching.
(B) Punching and reaming.
(C) Drilling.
(D) Drilling and reaming.

In this work special machine tools are used, among which pneumatic riveting equipment occupies the prominent place. The rivets are invariably very low in carbon for the content, and of a grade of material which will stand much heating abuse without showing deterioration. In hot riveting, as in the Cadillac and numerous other examples, advantage is taken of the shrinking of rivets when they cool. This pulls

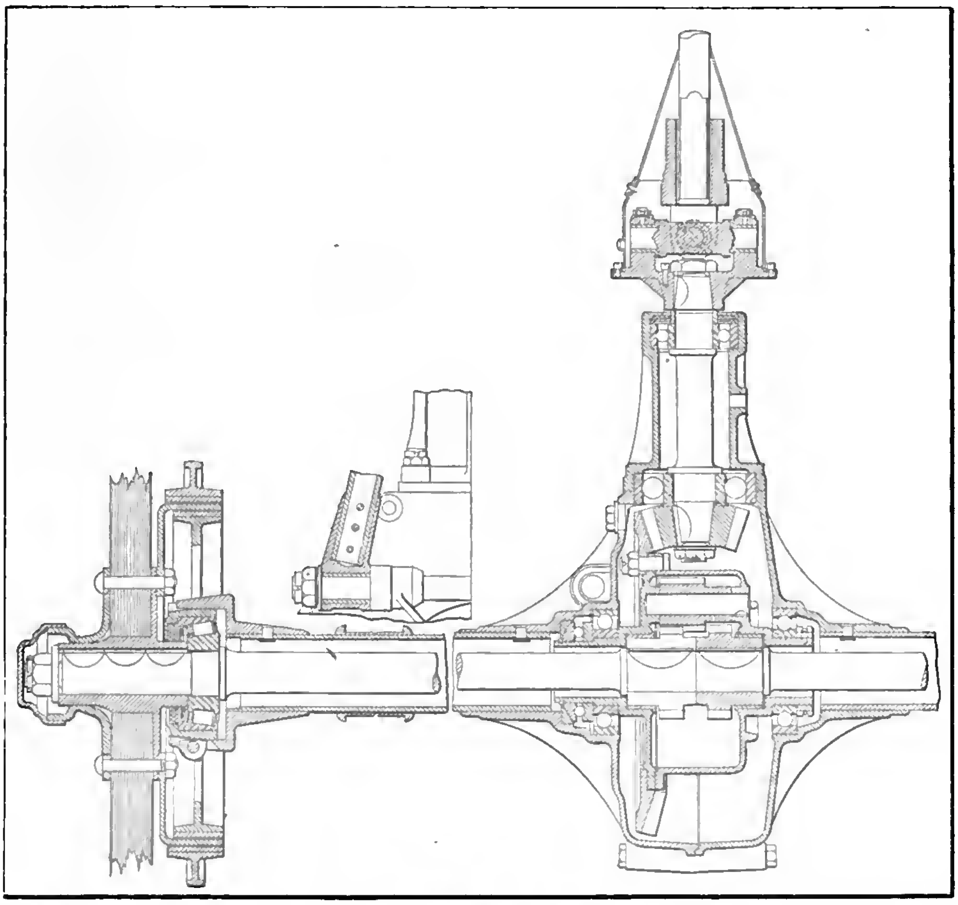

Fig. 9—Drawn steel brake drum and housings for universal joints, as used in Pierce-Arrow live rear axles

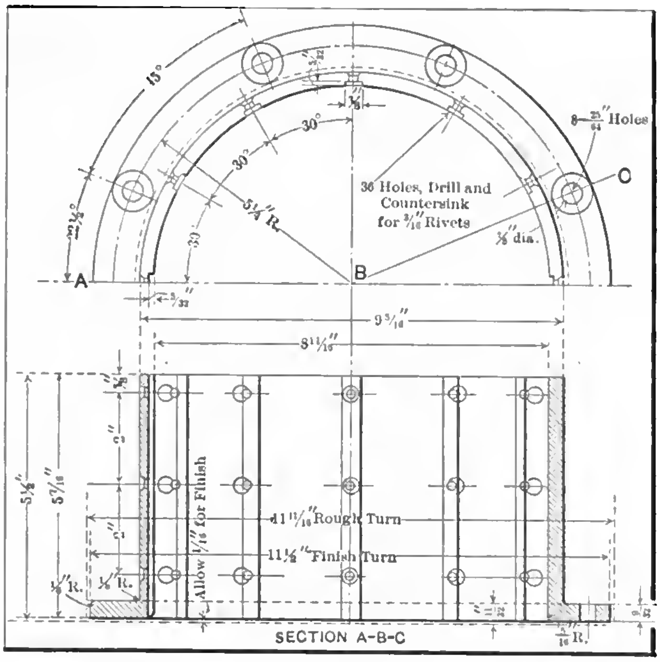

Fig. 10—Packard clutch casing of drawn steel housing the 1910 type of dry disc clutch

the plates into tight relation, thus preventing a tendency on the part of the members to work.

Cold riveting is very much in vogue, the rivets being of the same stock as when hot work is done, but with pneumatic tools it is possible to head up the rivets, considering good clamping during the performance, so that the members are brought closely together, and much pressure is exerted. It would seem, under the circumstances, as if riveting may be done by either of the methods, always with excellent results, provided the side bars and cross members are properly fitted, securely clamped and skilled labor performs the riveting operations.

WIRE WHEELS REPRESENT PRESSED AND DRAWN STEEL WORK

In wire wheel work the hubs (complete) are of drawn steel, the material being an excellent grade of acid open-hearth steel from a blend of Lancashire with Swedish ores, referring to the English wheel work, because in England wire wheels are considerably used. True, in England, second growth hickory is not available in quantity sufficient to allow of its use to the wide extent to which it is utilized in this country. It is believed that the enthusiasts who are booming wire wheels by calling attention to their wide adoption in England fail to appreciate the true reason.

The relative advantages of wire and wood when reference is had to wheel building is likely to be in favor of wood in the long run, and history, if it is worth anything at all, reflects credit upon wood in this class of work. At all events, following within the prescribed limits of this story, pressed steel is utilized now more than ever in hub, flange, cap, and even in the construction of the cup and cone bearing work, not to mention the almost universal adoption of drawn steel brake drums, rims for tires, and the parts which go into live rear axles at several points, this much, indeed, even if the whole axle housing is not of drawn steel, as it proves to be in such products as are turned out by the Timken Roller Bearing Axle Company and some others.

Pressed steel brake drums have many advantages, among which lightness is very noticeable indeed, but utility must have a resting place in the system if lightness is to take rank as an advantage. In many of the earlier types of automobiles the drums were cast from bronze, and after a few weeks' service they "spun" into a conical shape, it being the case that the brake-shoes acted exactly as does a tool in the hands of a workman who in the act of spinning metal applies pressure to a rotating sheet of brass, and gradually the metal eases away from the pressure, taking on such fanciful shapes as the workman may desire. The cast brass or bronze brake drums acted in the same way, and bronze, however good for other purposes, failed to give satisfaction in this class of service.

Drawn steel brake drums do extremely well in this service; they do not spin out; the rigidity of the metal is enough to absorb this action, and the close grain of the drawn steel is decidedly advantageous, since the surface afforded is well defined and very satisfactory as a friction surface, over which the friction lining of the brake shoes are enabled to run without being damaged, whereas for the coefficient of friction it is high enough for the purpose when the shoe-linings are of suitable materials, as follows:

(A) Parsons manganese bronze with cork inserts.
(B) Pressed steel shoes with copper facings and cork inserts.
(C) Steel casting shoes with copper facings and cork inserts.
(D) Pressed steel shoes with asbestos fabric facings.
(E) Steel casting shoes with asbestos fabric facings.

The coefficient of friction when the shoes are faced, if the facing is of the above or equally good materials, will range be-

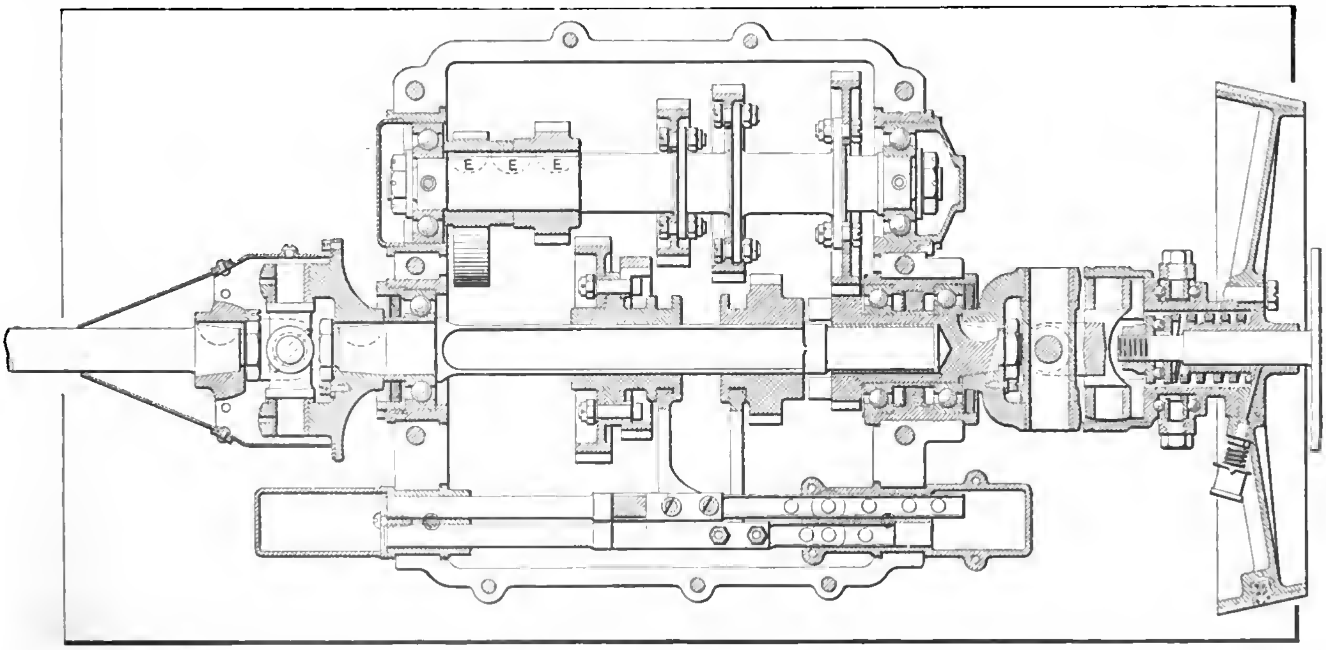

Fig. 11—Pierce-Arrow transmission gear and clutch assembly, with pressed steel housings over joints

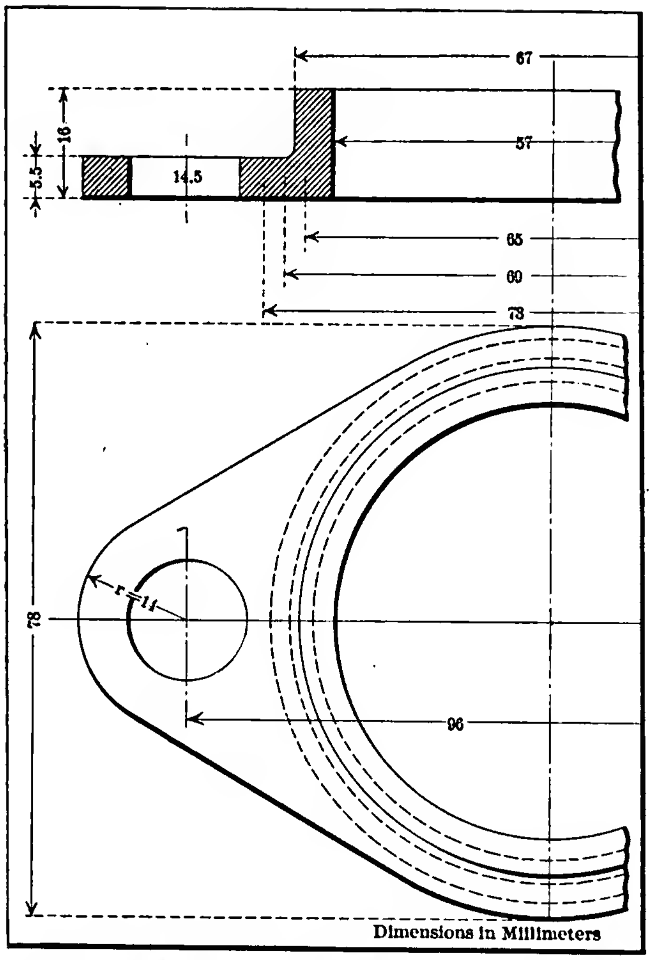

Fig. 12—Pressed steel flange for use with inlet and exhaust manifolds of motors

tween 0.20 and 0.30, nor does it seem to make much difference if oil is allowed to spread over the surfaces under certain conditions.

For illustration: In Premier cars the shoes are provided with cork inserts, and it is the usual practice there to apply grease to the drum faces, experience proving that the results are even better than they would be otherwise. The surface available for Premier brakes is something over 500 square inches, and it seems to be a property of cork to work quite as well with lubrication as without it. With such a large surface over which to spread the pressure, the brakes take hold softly but with great promptness, while the cork, being in sufficient presence, scrapes the grease from the pressure surfaces just as a rubber scraper removes water from a plate glass when the workman is cleaning windows.

Considering brakes: In the Marmon cars the drums are very wide, there being two sets of brakes side by side, and these drums being of pressed steel, of good diameter and suitably shaped, afford a large surface for the brake shoes. Nor do the drums show a noteworthy tendency to flare out, as they would were they of bronze.

Steel castings are used to some extent in brake drum making, but it is scarcely to be expected that the cost of the drums will be so low as when drawn steel is selected. The steel castings work very well indeed, although it has not been found in side chain drives, when the sprocket teeth are cut out of the steel castings, that they are not sound in every case. The enlargement which must be formed on the periphery of the casting to allow for cutting the teeth for the chain is very prone to cause trouble, owing to shrinking phenomena during the process of cooling of the castings, excepting in establishments of great competence, in which this class of work is dealt with continuously.

Brake drums in the best examples of the day arc from 12 to 16 inches in diameter, made of drawn steel, and are either integral with the hubs or flanged and bolted to the hub-flange proper, in which work the same bolts which are used to clamp the wood at the miter act as the flanging bolts for the drums. In shaft drive cars, and in view of the absence of sprocket teeth, steel castings serve very well indeed, and they frequently offer special advantages, it being the case that the design is such as to indicate their use. The steel castings are a little more rigid than drawn steel; the carbon content is much higher in the metal, and in view of this the hardness of the metal is greater. Some of the steel foundries make a specialty of this class of work, among which Isaac Johnson & Company, New York City; Lebanon Steel Casting Company, Lebanon, Pa; Thomas Prosser & Sons, New York City; Henry Hess, Philadelphia, Pa., and others, may be mentioned.

RAMBLER CUP AND CONE BALL BEARINGS

Cup and cone ball bearings are pressed from high-carbon plate, or they are case-hardened after being pressed from a suitable grade of cementing steel in which the carbon is very low, possibly as low as eight points. In the Rambler plant at Kenosha this work is conducted on a considerable scale, the facilities there being adequate for every need, and this is one of the plants which, primarily devoted to the making of automobiles, also

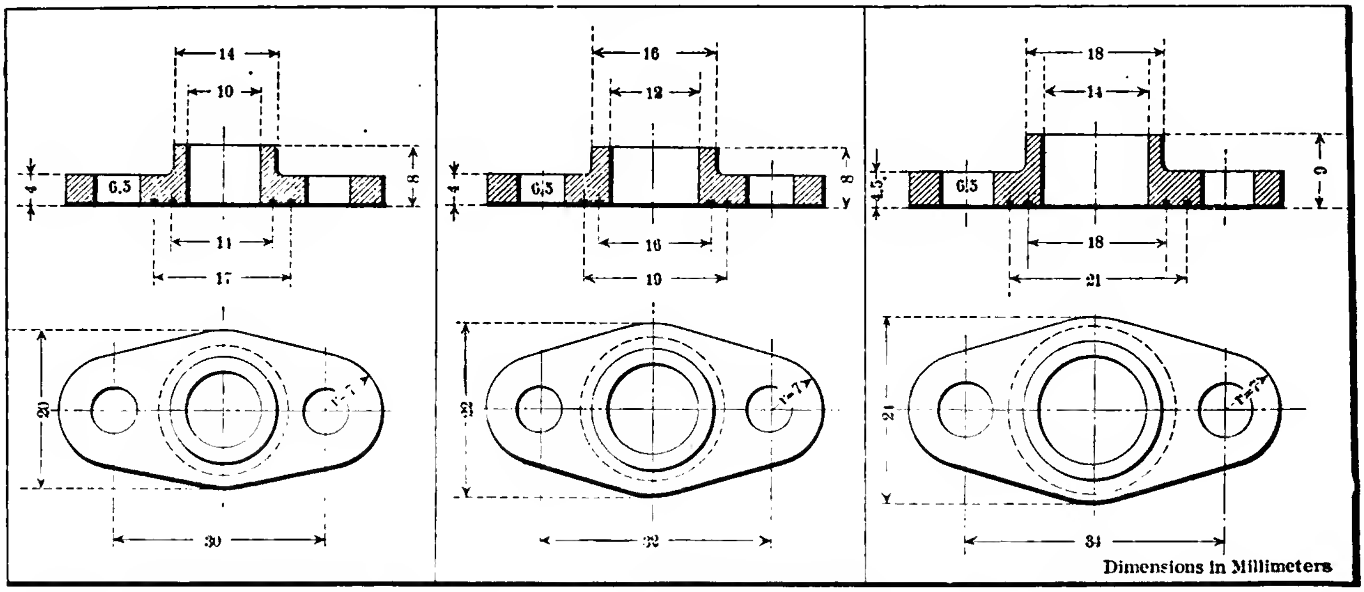

Fig. 13—Pressed steel flanges for use on motors in connection with water and gasoline piping reducing weight and adding quality

turns out all the anti-friction bearings used. The cup and cone bearings, of which there are a few excellent examples in Rambler cars, are also examples of pressed steel work. They are made from sheets of cementing steel, which are first reduced to the right blanking size, then pressed into the desired shape to produce cups or cones, after which they are heat treated.

In the heat treatment the cups and cones are first packed in hardening powder, which is largely ground bone, and the boxes of packed caps and cones are then placed in the cementing furnaces, raised to a cementing heat and allowed to "stew" for a length of time sufficient to grow a depth of dense carbon which will be sufficient for the needs. This growth of carbon will be a full thirty-second of an inch before the boxes will be removed from the cementing furnaces, and when they are withdrawn the mass of cups and cones are quenched in a bath for the purpose, thus rendering them nearly as hard as diamonds.

After cementation, the carbon in the shell is about 110 points, whereas the carbon in the core remains that of the original analysis of the metal, which is, say, ten points. After quenching, the parts are tempered to impart dynamic qualities. They are then ready to go to the grinding department to be finished. After grinding, the cups and cones are almost exact to size; the shell is highly polished all over the surface, and the hardness is that of the hardest steel balls, while the depth of the hard shell is 1-32 inch approximately. Under the hard shell is the relatively soft core; the shell rests on this core just as a frozen lake, so-called, has a sheet of hard ice over a cushion of water. The ice is stronger for the elastic support, it being impossible to deform it at a local point, as pressure is applied the ice bends, but the bend is spread out over a considerable area, and the extreme fiber strain is minimized.

PRESSED STEEL IN TIMKEN ROLLER BEARINGS

That pressed steel is limited to its application to cup and cone ball bearings is not to be held as true. It is employed in Timken roller bearings for the purpose of separating the rollers, the spacing member being a stamping in one piece from mild steel, and of a shape to be admired. In several of the examples of roller bearings, for that matter, the end spacers are of pressed steel, they being in the shape of washers.

REAR AXLE HOUSINGS NOW OF PRESSED STEEL

When the Ford car first came out the rear axle looked rather light, considering the type. In those days all live rear axles were of cast housing members engaging Shelby steel tubing. A closer examination of the Ford axles disclosed the construction—that of a drawn steel tube, which in appearance was a good imitation of a blunderbus of Colonial days. The tube started near the road wheels with the usual tube diameter, and as it approached to the differential gear system it was flared out to a sufficient radius to pass over, bulb-like, thus forming a housing for the differential gear and bevel drive.

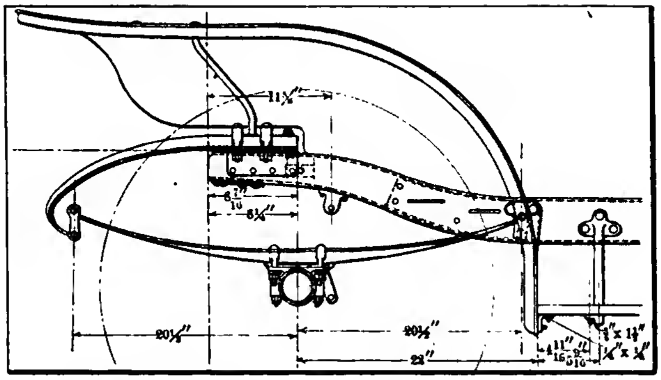

Fig. 14—Rear end of frame of Pierce-Arrow 6-36 Runabout, showing fastenings of 3-4 elliptic scroll springs

This idea of Ford's possessed the advantage of great strength; the material used was highly kinetic, and the weight complete was all that it should be. Prior to this innovation of Ford's it was proven in side chain work that rear axles should not be heavy, and in racing, as it thus obtained, in which I-section axles were used with side-chain drives, designers reduced the weight of rear axles of 90-horsepower cars down to as low as 36 pounds.

This construction proved to be good, and the Fiat people,

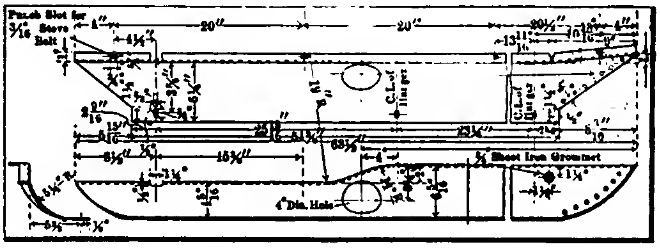

Fig. 15—Chalmers-Detroit mud shield, reaching from chassis frame to fenders

taking kindly to the idea, utilized the scheme, making some deviations from that as shown by Henry Ford. The drawn steel scheme, like every good construction, survived, and last year the Timken type of drawn steel axle was used on many automobiles, in which type the bell-shaped halves terminate in such a manner as to allow of the removal of the differential gear system, including the bevel drive. As a unit they nested within the confines of the drawn steel shell. This type of axle, like the Ford, has proven to be a diamond of the first water, and the Standard Welding Company, Cleveland, Ohio, make a specialty of the drawn steel as it is used in this class of work. As a matter of fact, one of the best attractions in the E. M. F. cars when they were launched on an unsuspecting public was this type of live

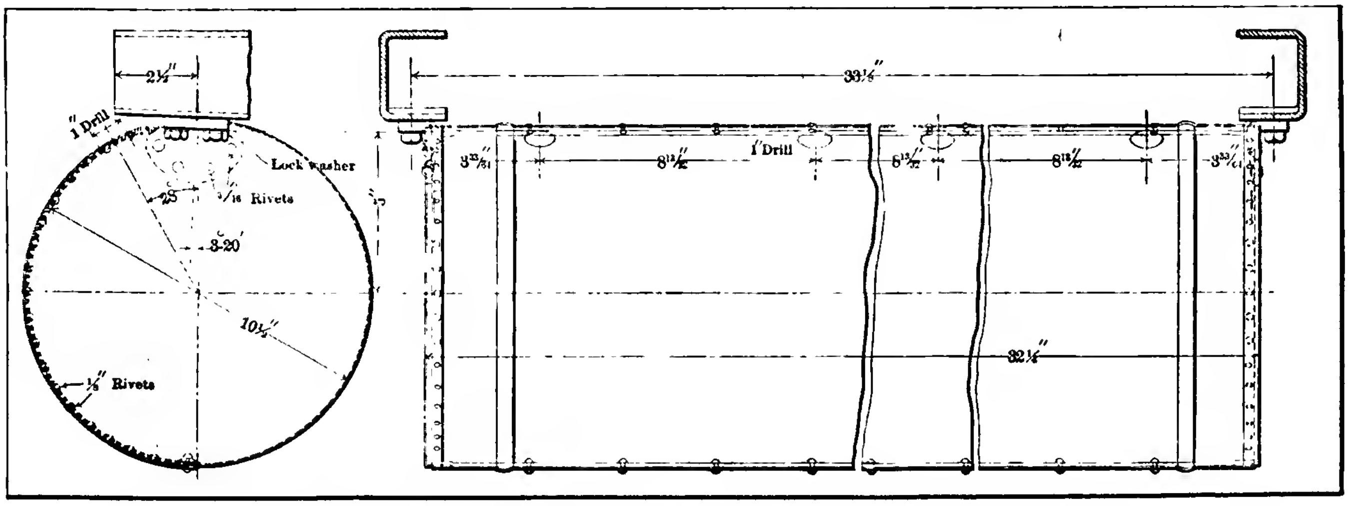

Fig. 16—American Simplex muffler shield, which protects the muffler in its position at the rear of the chassis

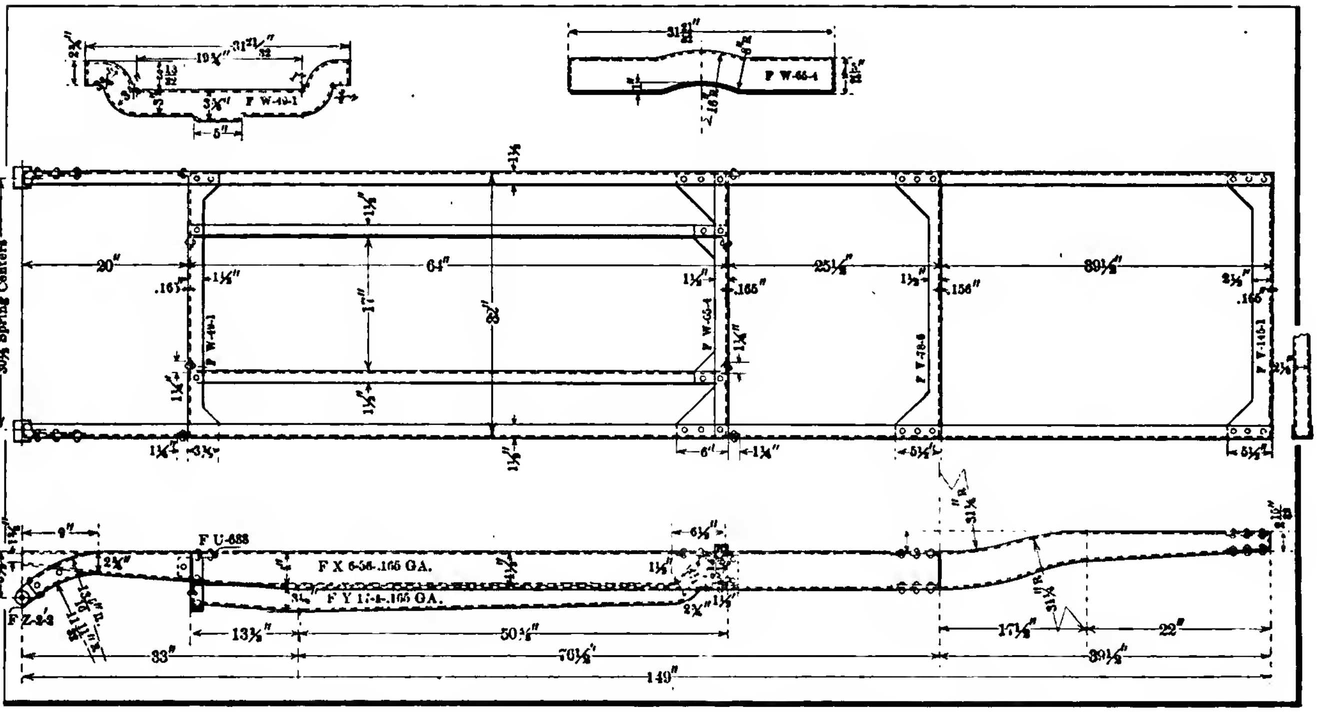

Fig. 17—Example of chassis frame with straight sides, a kick-up at the rear, and a subframe for the power plant made at the A. O. Smith plant

rear axle, and it proved to be one of the permanent features in the E. M. F., adding materially to its value.

DISTANCE RODS OF PRESSED STEEL

Another advanced investigator, Edward R. Hewitt, even before he formed the Hewitt Motor Company, took kindly to pressed steel, and in the long run the distance rods in the Hewitt trucks were of pressed steel. Moreover, they worked out to the entire satisfaction of users. It is better to put it this way, since designers may be satisfied without convincing users. In the Hewitt truck work the distance rods are of pressed steel, flanged and tapered, with neutral metal blanked out, and at the chassis frame end the female of a turnbuckle is riveted on; the other end is flanged to a bearing member, which in turn engages the rear axle in the right relation.

In some of the shaft-drive cars the radius rods are of pressed steel, one end of which members is flanged to the axle housing.

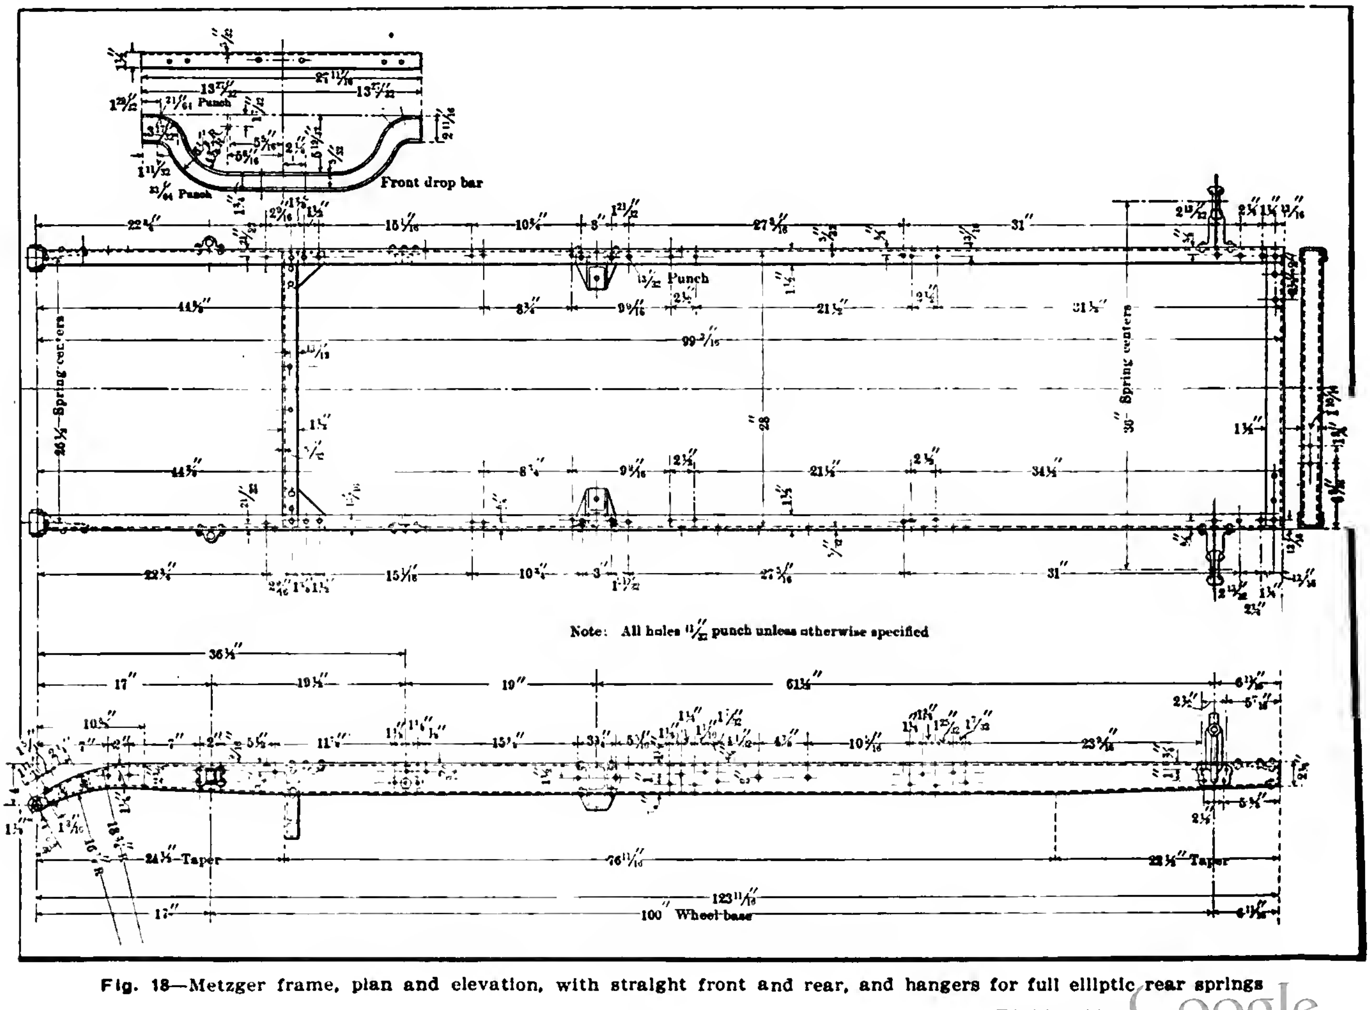

Fig. 18—Metzger frame, plan and elevation, with straight front and rear, and hangers for full elliptic rear springs

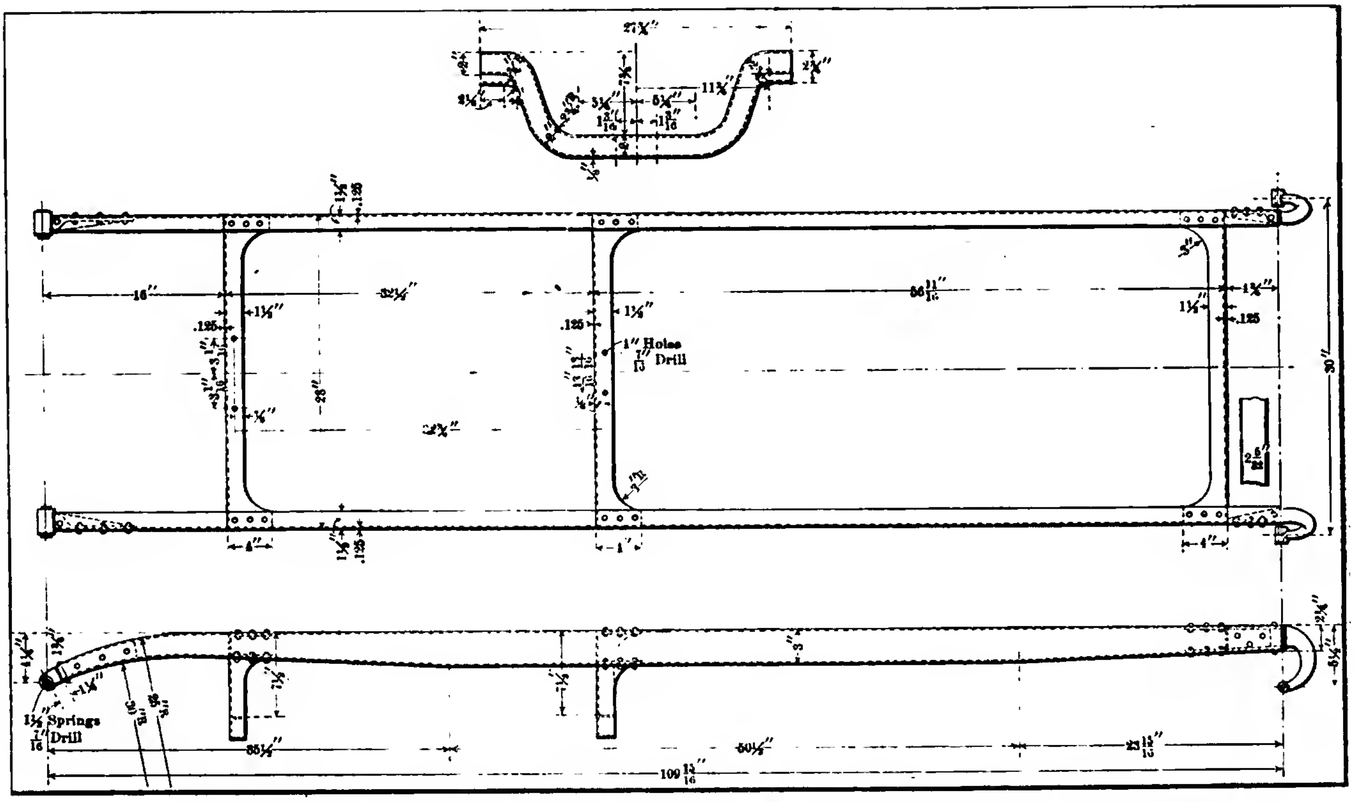

Fig. 19—Demot frame in plan and elevation, with straight front and rear, for semi-elliptic springs, and deep cross-bars

and the other end terminates at the universal joint, in suitable relation with the cross-member there placed, to take the torsion and thrust. This class of work has the virtue of being light; the strength of the material is in the plane of the work, and the general appearance is that of bridge building; bridges compel respect; they outlast man.

Housings for universal joints, which were formerly of castings, are now of drawn steel, and they offer advantages in several ways, among which are lightness, strength and neatness. Then there are covers for the bearings of transmission gears, they being formed in dies from mild steel, and when finished afford all that the situation indicated, besides having the virtue of being lighter, stronger, and at a far less cost than that of cast brass.

MOTORS HAVE PRESSED AND DRAWN STEEL

When water jackets have covers over them, the covers are sometimes of cast material, such as aluminum and bronze, but the examples of this class of construction, employing pressed steel, are growing. The steel work is, of course, lighter; the material used is much more stable than castings, and the finished motors look much neater. In some motors the crankbox has handholes for the purpose of inspection. They offer the further facility of adjustment of bearings if the occasion requires. The covers, while they were in former times of cast material, are now in some fine examples of pressed steel.

Motor cases, for the top half, either of cast gray iron or aluminum (the iron being now much used), in some of the good examples have pressed or drawn steel for the lower pan. Ford cars came out with this construction a couple of years ago, and while it was then recognized that Henry Ford had forced the hand of the pressed steel makers, it is nevertheless true that the idea was an advanced one, and after events proved that it was founded on good practice.

It is not now uncommon to observe that the lower half of motor cases are made in this way, and since the bearings for crankshafts are supported from the upper half, there is nothing

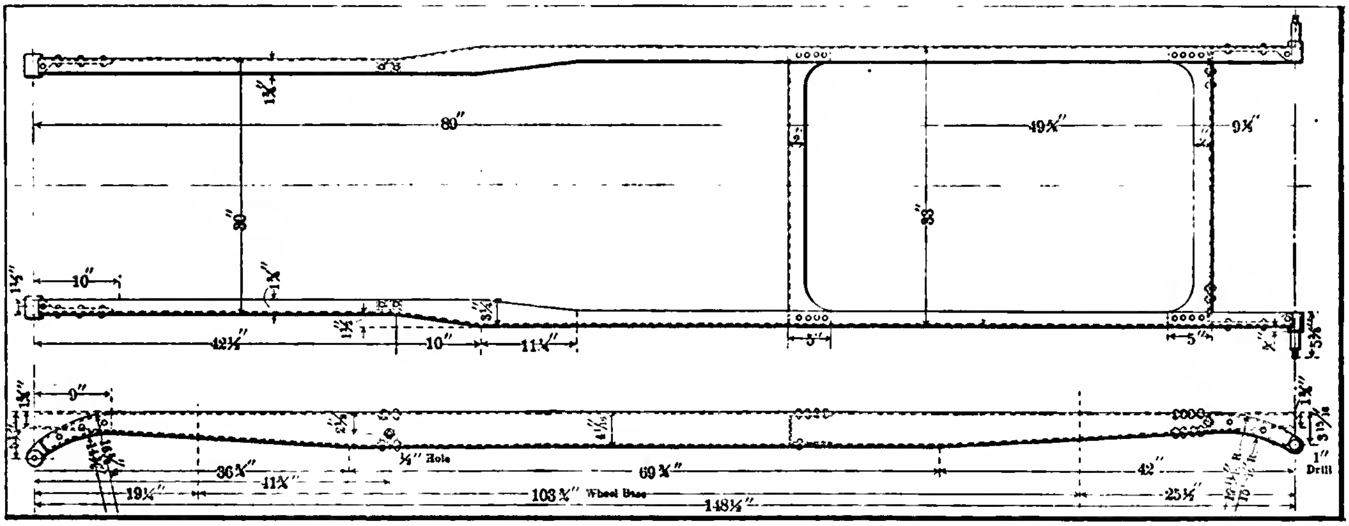

Fig. 20—Plan and elevation of Knox frame with narrowed front, straight rear and hangers for semi-elliptic springs

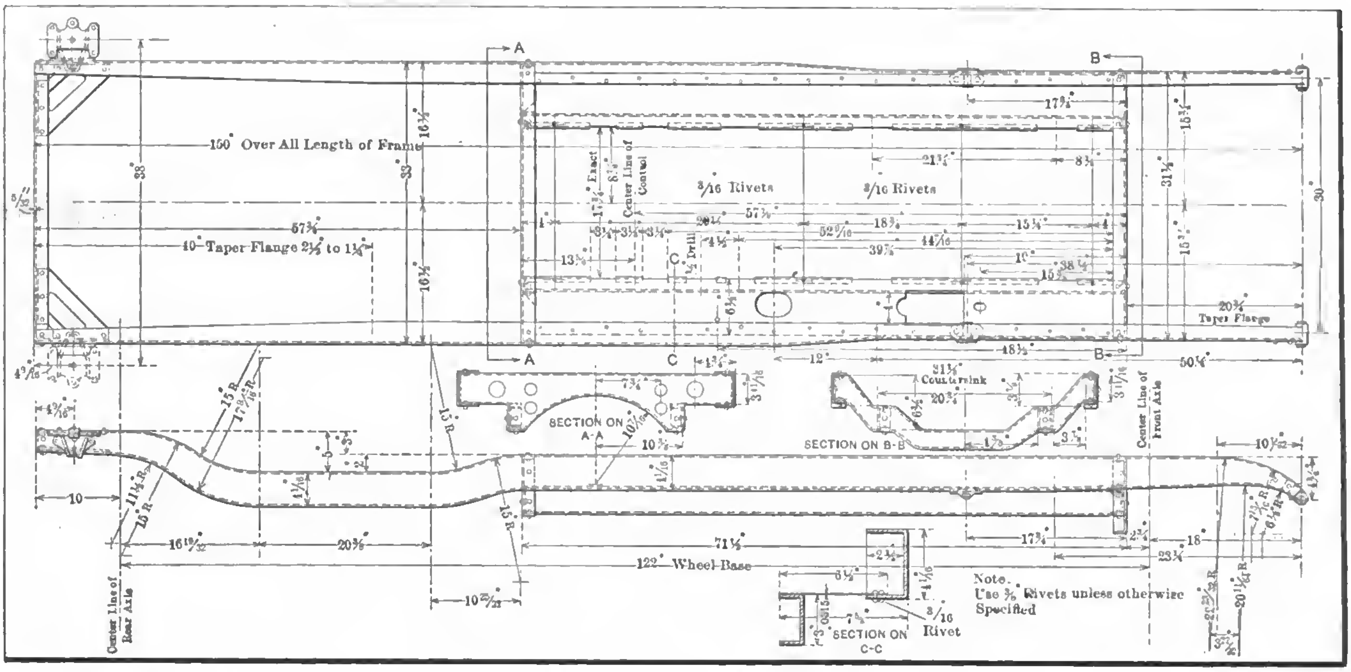

Fig. 21—Chalmers-Detroit frame in plan and elevation, with double drop rear and narrowed in front

for the lower half to support but its own weight and the lubricating oil that makes the foundation for splash lubrication. These pans, if such they may be called, are pressed hot in dies, and while it is something of a job, requiring several operations, the cost is reasonable and the weight of a motor is reduced to a minimum.

NOISE RESIDES IN BELL-LIKE MEMBERS

How to employ thin, bell-like members, and at the same time abort noise, is one of the first-rate problems of designers, simply because automobiles which are noisy will not be taken to kindly. When pressed steel is used:

(A) For the under half of motor cases;
(B) Covers for handholes in motor cases;
(C) Covers for housings of halftime gears;
(D) Plates over openings of water jackets;
(E) Housings for flywheels.

The metal being thin, of very rigid steel, and capable of making a considerable sound, must be so applied that this sound will be damped. Some of the designers resort to the expedient of applying a sheet of (thin) lead all over the inner faces of the covers, and in this way all noise is eliminated. To a considerable extent, if a packing is applied at the joints, noise is done away with, and if the plates are zinc-coated they are relatively still. That this problem is still to be coped with to some extent may be taken for granted, although in the Ford and other examples of lower halves of crankcases there is no trouble, owing to the damping effect of the lubricating oil which rests therein, it serving as a noise-killer as well as for lubrication. It is very likely that an electroplating of lead on one face of the plates would have the effect desired, referring to other pressed steel parts than the lower half of the crankcase, and the plating of lead, while it would act just as does a sheet of the same material, would be more cheaply applied, and less of it would have to be used, so that the added weight would not have to be tolerated to so great an extent.

OTHER PRESSED STEEL MOTOR REFINEMENTS

In Pierce-Arrow automobiles, and in some other makes as well, baffle plates made of pressed steel are placed at the bottom of the stoke in the cylinders, it being the idea to eliminate excesses of splash, and since the connecting rods play in a slot in the plates, and a restricted room is afforded for oil to be sucked by into the combustion chamber. This, as well as serving in the capacity

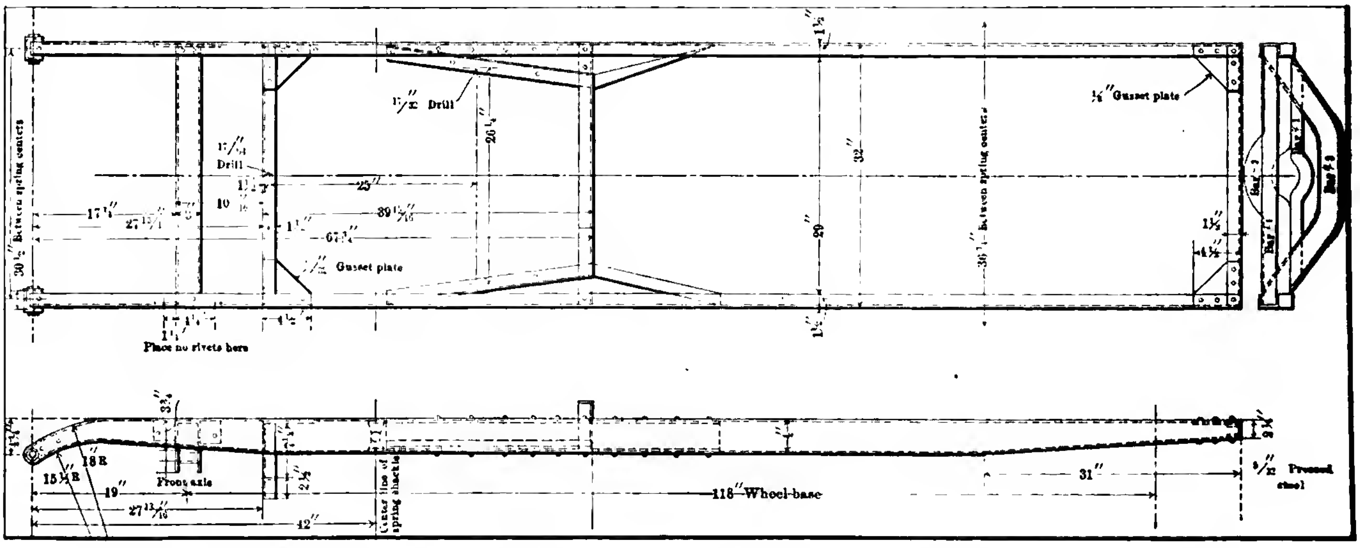

Fig. 22—Inter-State frame in plan and elevation, with four cross members, and side bars straight in front and rear

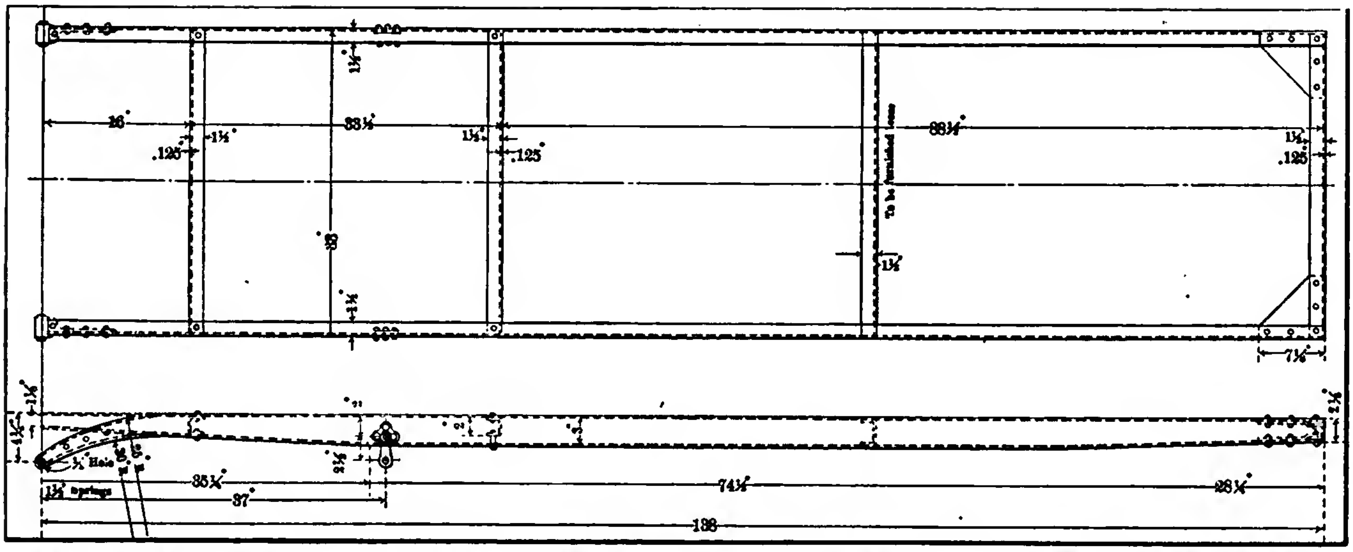

Fig. 23—Schacht frame in plan and elevation, showing straight front and rear, and four stout cross members well disposed

of a lubricating trouble preventer, makes for lubricating economy, because a considerable amount of lubricating oil will migrate by the pistons if it is allowed to perch on the walls of the cylinders, and carbon trouble will present itself.

Moon automobiles, as made by the Moon Motor Car Company, St. Louis, Mo., offer still another application of pressed steel in connection with its lubricating system. In this example, which has the added virtue of working extremely well, the lubrication to the crankshaft bearings is controlled by plates (which look like saucers) so placed on the ends of the main bearings that the lubricating oil, as it is forced through the main bearings and out, dribbles down over the surfaces of these pressed steel plates and is whisked off by the throws as they travel around, thus landing the oil on to the crankpin bearings, where it enters. That a state of positive and profuse lubrication is the result has been adequately proven by many cars in service.

National cars, in connection with the National system of lubrication for the motors, have a false bottom in the motor case, the same being formed in dies from steel, with a flange which engages a ledge around the aluminum case and a packing of piano felt is placed between the faces; this packing serves the dual purpose of making a tight joint and aborting noise.

This false bottom is provided with openings at eqnidistant points from the extremities, which openings are flanged upward and the height of the flanging measures the depth of the lubricating oil, which is held in the false bottom for use in the splash system of lubrication. The true bottom in the National is formed in the lower half of the crankcase proper, and a pump is there placed, its function being to raise the lubricating oil up into the system through its proper passageways, and it is this oil, on its way back to the basement of the crankcase, which catches in the false bottom, serves for splash purposes, and the excess runs down through the flanged openings to the sea of oil below It is filtered and screened in transit.

A DIVERSITY OF PRESSED STEEL MEMBERS

Some magnetos are provided with a leather hood, the function of the same being to ward off water and the silt of the road, which in bad going enters through the radiator. In many excellent examples instead of leather pressed or drawn steel is used and it has the especial virtue of fitting down over a packed face, thus rendering the magneto immune from attacks of dirty water, and, with proper quick detachable fastenings, it is allowable to quickly remove the cover and get at the magneto.

Battery boxes are now almost invariably made of pressed or drawn steel, and besides being neat in appearance, they are strong, water tight, and are particularly suited to the work

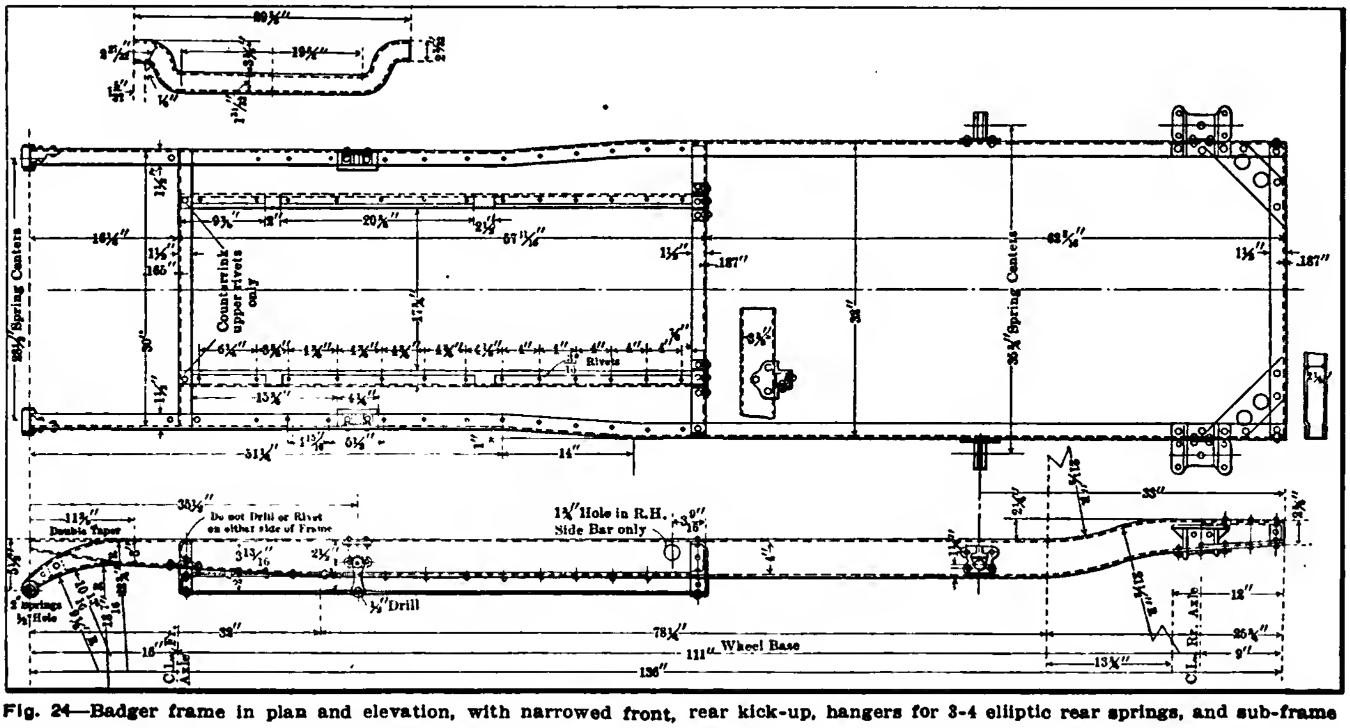

Fig. 24—Badger frame in plan and elevation, with narrowed front, rear kick-up, hangers for 3-4 elliptic rear springs, and sub-frame

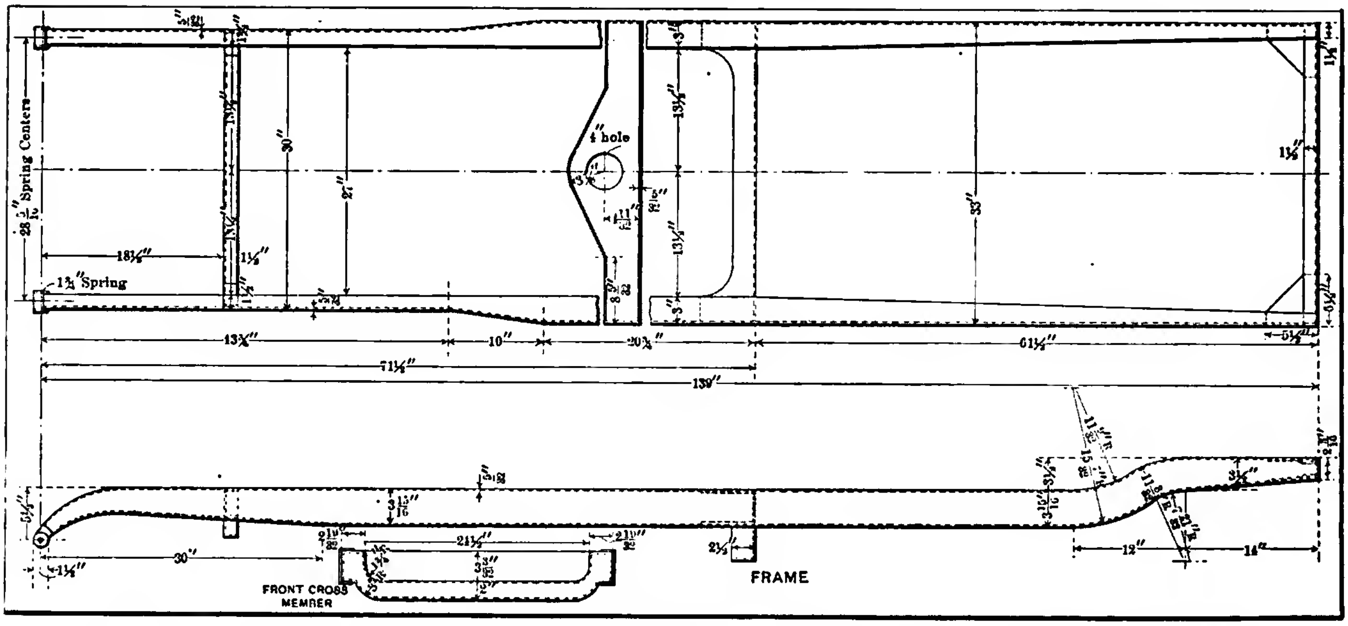

Fig. 25—Moon 30 frame in plan and elevation, showing straight front, rear kick-up, drop cross members, and stability

These boxes are provided for the dry batteries and in connection with the Patterson system of battery connections as made and sold by Stanley & Patterson, New York City, there is every evidence of refinement adequately associated with service.

Gasoline tanks of drawn steel coated with zinc (galvanized) are now in quite common use, and, being made with hemispherical heads with a single lap-joint at or near the midposition around the girth, they are strong, even though the weight of metal used is relatively light. These tanks are made in divers sizes, are provided with all connections as (a) inlet, (b) outlet, (c) filler, (d) for pressure, and when desired a measuring device will be provided with them, this having the utility of showing how much gasoline is in the tank. These tanks are held in stock at supply houses. Charles E. Miller, for illustration, invariably keeps a supply of the several sizes in his several stores, and will fit to the tanks the measuring instruments before shipment.

Tool boxes are quite generally of pressed or drawn steel, and in many cars the battery and tool box are of precisely the same general appearance, both being provided with locks. These boxes are seamless, made of a good weight of metal, and if securely placed on the running board they cannot be entered by a sneak thief, excepting at the expense of more labor than a person of this caliber will willingly contract for.

Pressed steel dash work is much in vogue, it being used in all automobiles excepting the ones which cling to the mahogany dash, and a few of those which go out with an overhang. In this latter instance the dash portion is of wood in some cases. This pressed steel work is very serviceable and the appearance is satisfactory as a rule, although in some of the earlier examples it did not compare favorably with mahogany work from the point of view of appearance, which has its influence.

Steering wheel spiders to some extent are made of pressed steel, this material having originally been brought out in the B. L. M. cars. The general appearance of the spiders so made was a little against them because they looked light to purchasers, they, to some extent, failing to appreciate the difference in strength which exists between pressed steel and cast aluminum.

Windshields, especially the framing (sash), are made in such a way as to accommodate a packing between the engaging members and the glass, and while some of the material used in the

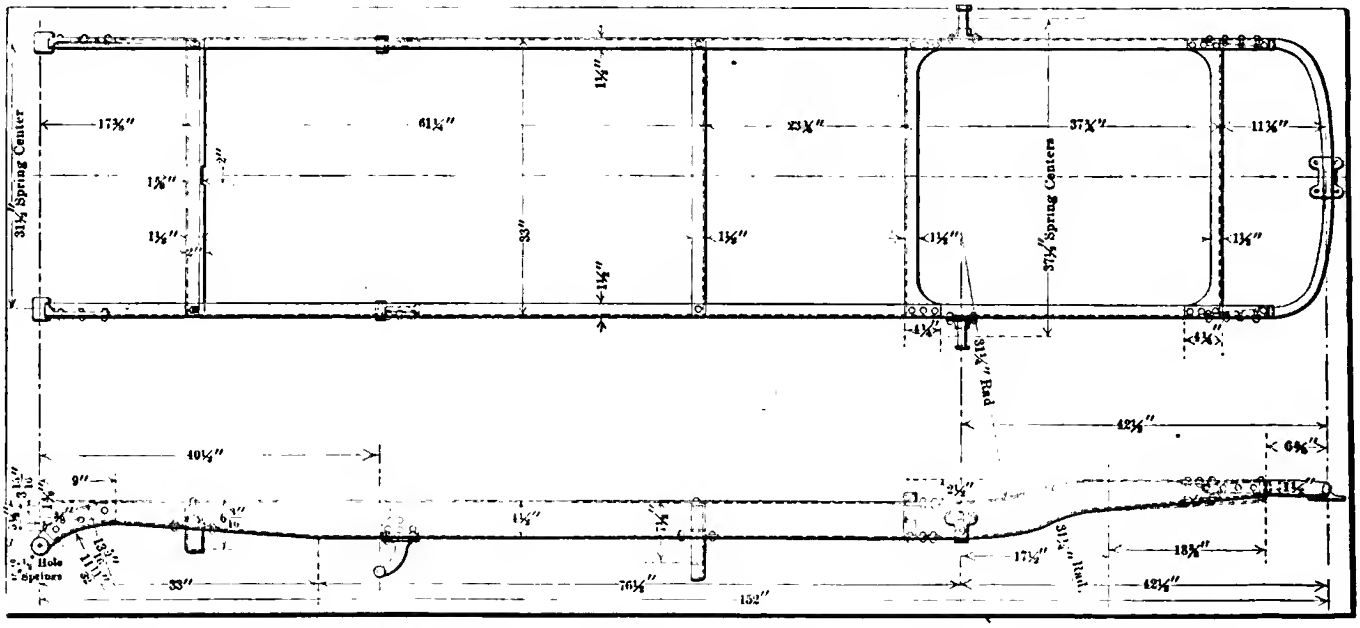

Fig. 26—Corbin frame in plan and elevation, with straight front, rear kick-up and supports for platform springs

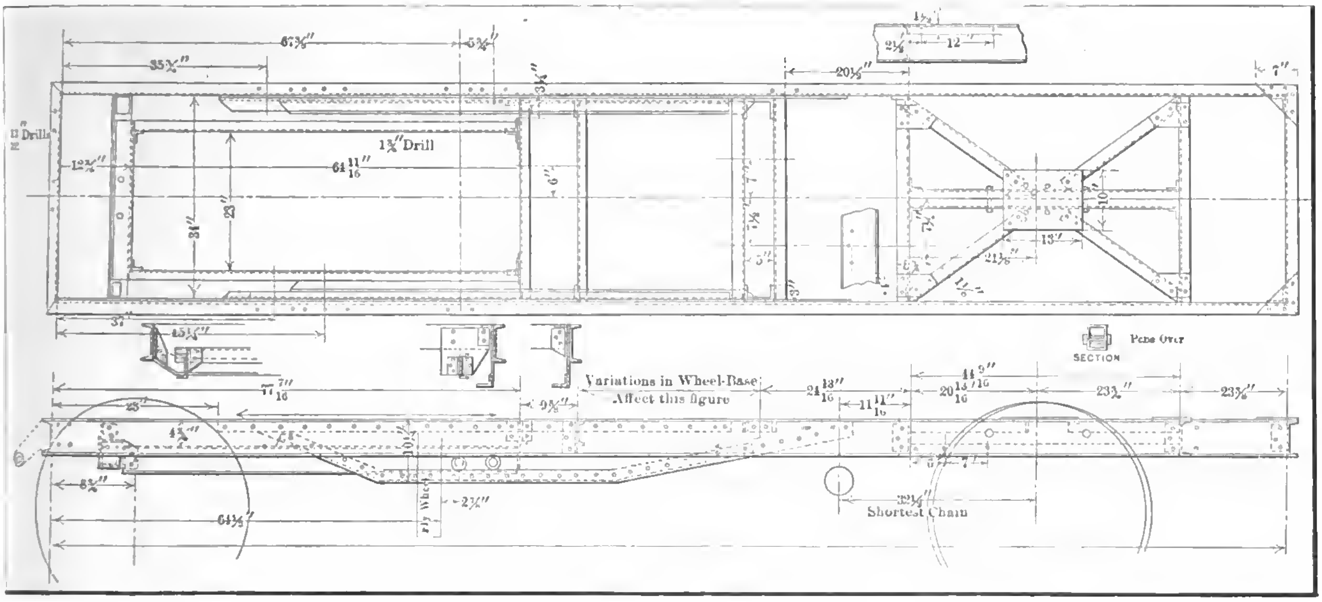

Fig. 27—Alden Sampson frame in plan and elevation,, channel section with flanges out, designed for heavy trucking service

sash work may class as other than pressed steel the most of it is either pressed, rolled or stamped. It is the aim of makers of windshields to get away from the use of brass castings to the greatest possible extent, and plated steel offers the widest opportunity. Some excellent examples of windshields were shown on the cars of this year's vintage.

Lamps, to some extent, are of drawn steel. Then there are parts of the lamp-shells which are pressed, although to be sure brass and copper stampings or sheet brass dominates this field. As an extreme example of pressed steel work, reference will be made to the steel plates used in the making of the elements of the Edison battery.

SOD APRONS AND MUD GUARDS OF PRESSED STEEL

Sod aprons, so called (under pans for motors) are made of sheet steel and in the best examples they are formed in dies. There is still some room for improvement in this line of work, notably in the methods employed for fastening the aprons in place, for if they are not securely fastened they will fall off, or noise will greet the ear of the owner of the car in any such event. If the fastenings are secure, but difficult to undo, the time required in which to examine the under side of the car, or make a repair, will be excessive in all probability.

Mudguards in nearly all of the recent examples are formed of steel. Aluminum is still in vogue to some extent, but steel answers every requirement, is more lasting, taking it on the whole, in view of the mudguards which now extend down to the chassis frame, steel is suitable metal, and for a good shape it is necessary to employ dies in the process, so that this work takes rank as pressed steel, although a press of the conventional sort may not be used in the process.

Running-boards are now almost invariably of pressed steel, the stock being relatively heavy in pounds per square foot, but to make the running-boards light as well as rigid, they are punched out, leaving about 50 per cent. of the total weight of the original metal. These boards are rendered strong by having flanging at the two edges, and they are also properly shaped to neatly engage the mudguards, to which they are bolted. The running-boards are properly bolted to brackets, which are also of pressed steel, and in this undertaking, it may be as well to say, it is a distinct advance over the older method of forging brackets out of iron, in which forgings welds were necessary, and they did not always hold securely. It is also true of the newer pressed steel brackets that they very materially add to the general appearance of the cars, and are much lighter.

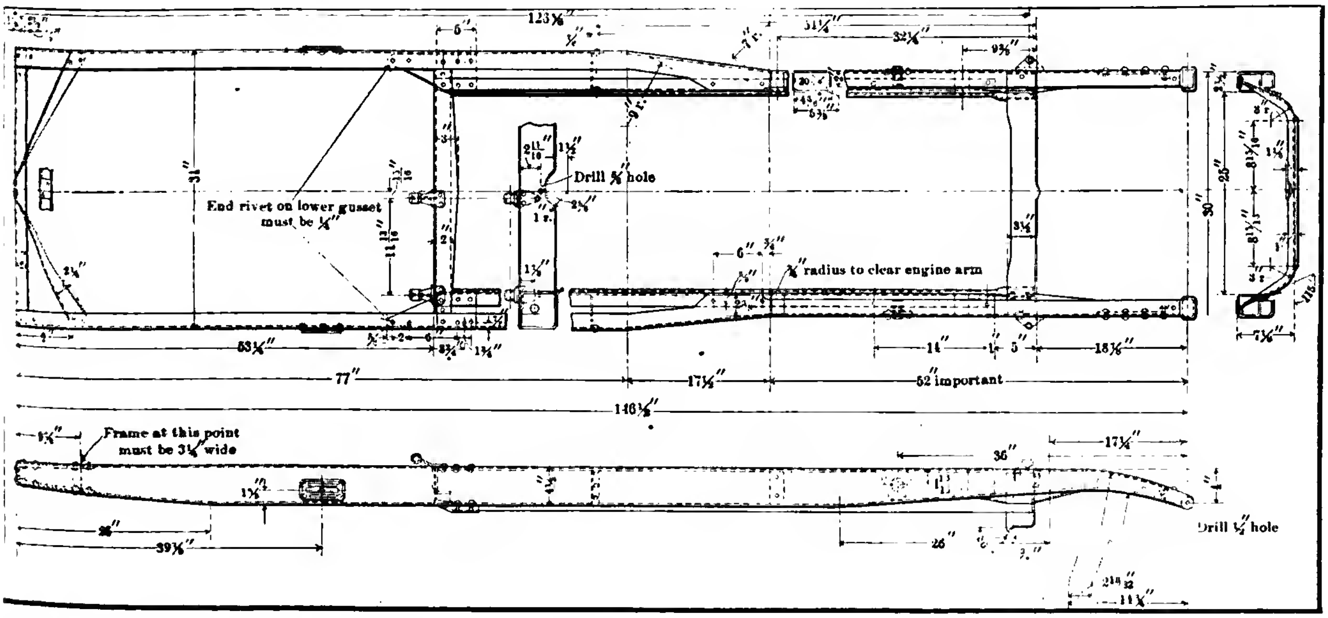

Fig. 28—Premier frame in plan and elevation, with narrowed front, for semi-elliptic rear springs, and extra means of support at offset

STOVE BOLT FASTENINGS OUT OF FASHION

In many of the earlier examples of cars, when tinsmiths were held responsible for the proper fastening of the mudguards, it was not uncommon to observe that the work was done on a basis which obtains in fitting up a kitchen range, with this exception: it was not so good, due to lack of familiarity of the range-fitters with automobiles. This stove-bolt idea clung to automobile work with a good deal of tenacity and it is a great gain to be rid of it.

MUDGUARDS ARE JAPANNED FOR PERMANENT FINISH

With the increased use of sheet steel in connection with the production of mudguards and like parts, the question of a permanent finish had to be coped with, and in such cars as the Cadillac, Rambler, Premier and others the parts are japanned in any desired color, and after the japan is baked on it takes a high finish, besides having the necessary virtue of being permanent.

EXPERIENCE IS FULLY TAKEN ADVANTAGE OF

That pressed steel has materially reduced the repair accounts of the owners of automobiles is one of the matters that can readily be taken for granted. Were failures properly tabulated and compared, it would probably be found that fully 50 per cent of all troubles are in connection with the injudicious use of castings, whereas, in connection with pressed steel, it is not far from the truth to avow that there are few, if any, failures come from the use of this excellent material when it is judiciously applied. Even when it is subject of an unfair amount of work it is far more likely to survive than will be true of any other material, due, in some measure, to shape.

Pressed steel is superseding drop forgings to a far greater extent than would be supposed. With modern facilities for making dies, and the relatively large presses now in use, the process lends facility to many undertakings, and, to a considerable extent, even drop forgings are being displaced by them. In a certain measure pressed steel is superior to even drop forgings, due to the better condition of the material after the process is completed, even when the work is carelessly done.

When parts come from the forge in the drop process they are in a poor state, and, unless they are subjected to a correcting process, it is even possible to say of them that they are not fit to use. There is no process which can be devised that will lend itself without any failures, and, as is generally well understood, heat-treating work is not simple, and failure is courted to some extent every time a bulk of steel is brought up to a temperature above its critical point without due regard.

In a certain degree this is true of pressed steel; it too should be annealed after it is formed. The dangers involved are, in magnitude, relatively slight, owing to the shape of the metal and to the amount of work previously expended upon it to bring it into the flat state.

Before concluding it is desired to state that the dates on the views of the A. O. Smith plant, as shown in Fig. 8, tell of the speed made in the erecting of this plant, and, as to its size, it is over 1000 feet long and has a foot in width for every day in the year (approximately), representing, in a sense, the growth of the accessory industry and magnitude of building operations.

TYPES OF POWER PLANTS

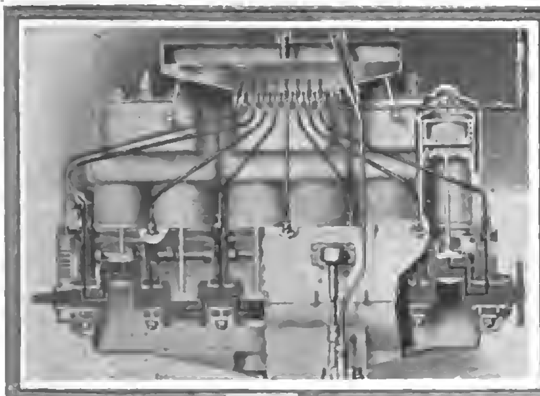

FIG. I

Section of Pierce "six" motor, showing crankshaft, half-time gears, twin cylinders, and method of oiling

ELECTRICS were the first to come into vogue, and while the electrical undertaking, considering it as a whole, may represent a very considerable effort, during which divers ideas were tried out and some of them found wanting, still commercially the principle remains, and in its refined state, as it is presented today, electrical vehicles serve with great distinction in a definite field of usefulness. In discussing types of power plants as they are utilized in automobiles generally, it would be to cover the subject but poorly were the electric situation ignored. In view of restricted space, there being so many points to cover in reviewing the exhibitions under the auspices of the A. L. A. M. at the Garden, it will be necessary to limit illustrating and discussion so that the electrical situation is reduced to a single display merely to afford it the recognition to which it is due, which illustration (Fig. 2) is of a Waverly power plant as it is placed under the body of a Waverly electric vehicle.

LONG STROKE MOTOR IN GOOD PRESENCE

It is in gasoline work that the greatest strides were made, and it would take many pages of space, with hundreds of illustrations, to adequately indicate the extent of activity in this field. If the electrical power plant ranks first in the line of development, it is true in gasoline work that the "six" comes at the end.

The title illustration, which is of a Pierce-Arrow, presents evidences of the refinements in this class of power plants, and this refinement is very general in all the products. The condition is reflected in the fact that the "sixes" are confined to the higher priced automobiles. At the Garden these plants were present in

Cars costing from $1,500 to $2,500..................	5
Cars costing $2,500 to $4,000.......................	12
Cars costing $4,000 or more........................	40

In the "sixes" there are few indications of innovations, it being common practice to adhere to well authenticated plans, with cylinders cast in pairs, lubrication by special definite pumping methods in addition to splash systems, and ignition by means of a magneto in every instance, and always attended by a coil and battery which is used in cranking, noting exception that Winton has an automatic starter.

The long stroke has taken a hold in this class of work, and in the Thomas Model "M," which is a 4 1-4 x 5 1-2 bore and stroke, respectively, for illustration, this idea is regarded as of excellent virtue. This long stroke advantage, instead of being confined to a few cars, is very generally maintained, the Winton, for instance, being a 4 1-2 x 5; Mitchell Model S, 4 1-4 x 5; Premier 6-60, 4 1-2 x 5 1-4; Lozier-Briarcliff model, 4 5-8 x 5 1-2; Pierce-Arrow 36-horsepower, 4 x 4 3-4; Pierce-Arrow 66-horsepower, 5 1-4 x 5 1-2; Matheson 50-horsepower, 4 1-2 x 5; Alco 60-horsepower, 120 x 140 (milimeters), bore and stroke respectively.

It will be observed that the length of the stroke, as compared with the bore, does not represent a large percentage, but the extent of agreement in relation to the long stroke is fairly reflected in these figures. With a view to showing the other side of the story, attention is called to the Knox Model S, which is 5 x 4 3-4; Oldsmobile "Limited," 4 3-4 x 4 3-4; Franklin Model H, 4 1-4 x 4; Stevens-Duryea Model XXX, 4 3-4 x 4 1-2, bore and stroke respectively. Taking the motors as they actually obtain, and considering the designs on both sides of the long stroke question, the situation favors the conclusion that departure from the square cylinder, in which the bore equals the stroke, is but slight in favor of the short stroke, and just enough to notice in the direction of the long stroke. There are fine examples of automobiles on both sides of this question, and they have all been on the road doing good work long enough to inspire confidence.

This question of bore and stroke, as it relates to the six, is substantially reflected in about the same way down through the "fours," and possibly into the "twos," but there is a distinct change when it comes to one-cylinder cars, of which the Garden, however, presented none at all, so that this phase of the subject will not have to be discussed here.

VARIOUS TYPES OF FOUR-CYLINDER MOTORS

Valves in the head seemed to favor a high-weight efficiency, and the excellence of performance in other respects commanded the attention of some recognized designers. Fig. 3, of a Stoddard-Dayton, shows one of the very competent engineering methods by which this type of motor is consummated. There are other good examples of valve-in-the-head motors—for instance, the Moon, Model 45, and others. In the Stoddard-Dayton, as illustrated, it will be observed that the valves may be quickly removed, and that ample means are at hand for assembling to tightness, because the cage is so fashioned as to compensate for heat changes. The carbureter on this motor is a multiple nozzle type, connected through a well-designed manifold, and the motor is said to operate with rare flexibility. The cylinders are cast in pairs, which is quite a common practice.

The Premier Model 30 motor, as shown in Fig. 4, is offered as an example of a four-cylinder motor with T-headed cylinders. The motor is shown on a working stand, turned 90 degrees, with the under half removed, exposing the crankshaft, showing that it runs on three bearings and that the lower halves of the journal

boxes are bolted to the top half of the case. This practice is regarded as thoroughly good in every way, and is utilized to quite some extent in representative motor work. The cylinders are shown detached below, cast in pairs. Fig. 5, which illustrates a National four-cylinder motor, shows by way of distinguishing features that the magneto is flexibly assembled, there being a double universal joint between it and the shaft which drives it.

Fig. 6, of an Excelsior four-cylinder motor, is of the L-type of cylinders, with the magneto driven from a gear which meshes directly with the half-time gears. A double Oldham joint gives flexibility of the mounting.

Fig. 7, of the Metzger motor, which is a relatively new product, differs from all the others shown, and represents a new feature of construction which will be watched with much interest. The four cylinders, which are L-type, are cast integral with the other half of the crank box, all of gray iron, and the round tank which nests in the mid-position is for lubricating oil. It is of a commodious size, and so situated as to collect heat units from the cylinders nearby. The motor has the virtue of being very completely enclosed with relatively few parts, and the commodious flywheel adds materially to its ability by way of flexibility and the facility of operating at a very low speed.

INDIVIDUAL CYLINDERS ARE IN EXCELLENT PRESENCE

In the Rambler plant at Kenosha, Wis., the power plants for all models are designed with individual cylinders, as shown in Fig. 9, and the crank box is the possessor of a distinct innovation, which cannot be disregarded in the search after quality.

FIG. 13

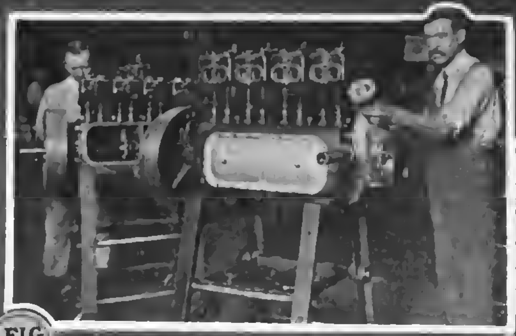

FIG. 9

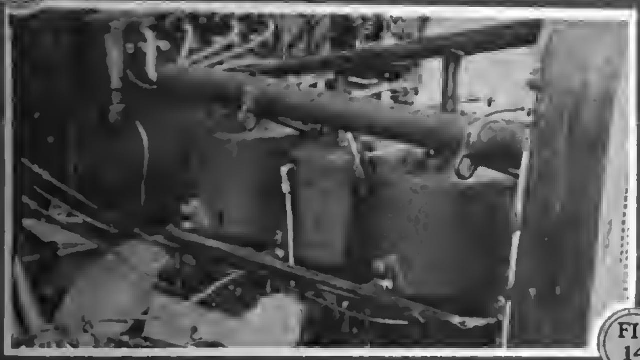

FIG. 14

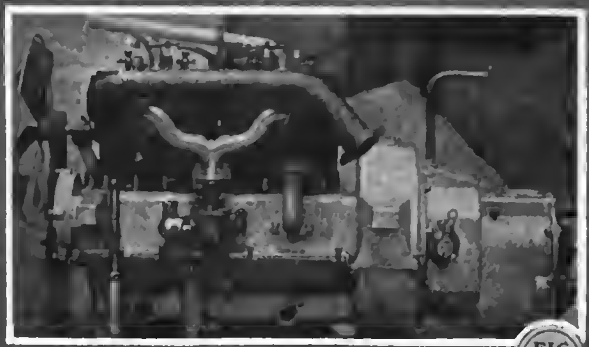

FIG. 10

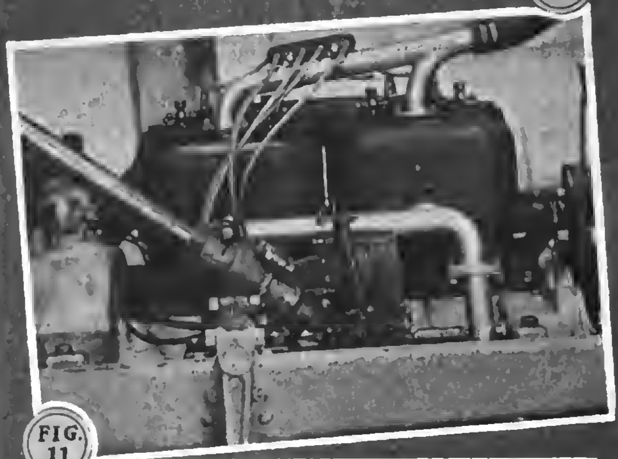

FIG. 11

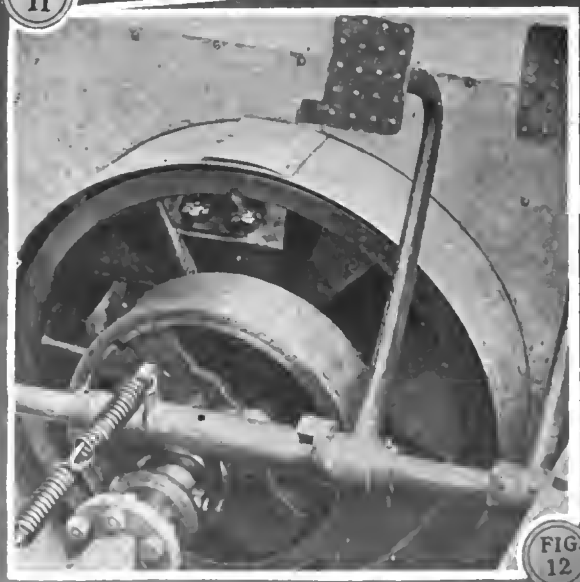

FIG. 12

Fig. 9—Rambler motor with individual T-type cylinders and undivided crankcase, using one camshaft

Fig. 10—Patterson 30 motor, showing individual power plant, enclosed clutch and transmission, and Schebler carbureter

Fig. 11—Cole 30 power plant, unit type, with four cylinders cast in pairs, and enclosed clutch and transmission

Fig. 12—Moon power plant, showing fan in flywheel, expanding band clutch, and means of control

Fig. 13—Alden-Sampson power plant, showing half-time gears, positively driven fan, and refinements

This crank box is made without being split on the horizontal center, and a large handhole which is placed on the working side permits of inspecting and adjusting ball bearings on the crankshaft and connecting rods at will. The further advantage which is present in this design lies in the fact that the thrust on the pistons due to gas work comes on the solid section of the crank box, rather than upon holding bolts, which would be true were the box made in two halves. This example presents evidences of a distinct school of design.

UNIT TYPES OF POWER PLANTS VERY PREVALENT

The Patterson 30, as shown in Fig. 10, is an excellent example of the unit type of power plant, as it is being exploited in a considerable percentage of the relatively low-powered automobiles as they were shown this year. In nearly all these examples the cylinders were cast *en bloc*, and while the Chalmers 30 has a sufficiently husky power plant to show that this type of construction is by no ways limited, the fact remains that it is much favored in the relatively small cars.

Departing from the block cylinder feature, it will be possible to point out that the unit type of power plant is utilized to excellent advantage in connection with other cylinder designs—as in the Stevens-Duryea power plants. Fig. 11, of a Cole 30, is an illustration of a unit type of power plant with the cylinders cast in pairs and thermo-syphon cooling. Fig. 12, showing the flywheel end of the Moon car, illustrates one way of propelling air through the radiator in front, over the surfaces to be cooled and out under the car. In this example the fan blades in the flywheel are so designed as to draw all the air which can be efficiently utilized even in the absence of a disc fan back of the radiator.

HOW CARBURETER PROBLEMS ARE SOLVED

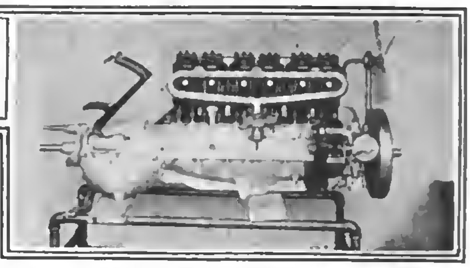

Fig. 1—Anhut motor, showing application of Stromberg carbureter

SINCE Daimler's time, the vaporization of liquid fuels has been a big problem, which, as time passed and the supply became poorer and poorer, increased in difficulty of solution. In the meantime, as the fuel became worse and worse, designers made much progress, and would have made more had the fuel remained uniform. However, with the present day fuel, poor as it is, the present day designers have arrived at a nearperfect condition of vaporization. Following a number of important moves toward and away from several specific designs or, more correctly, principles, a general type has been evolved from which all carbureters differ slightly, but from which no one carbureter differs in its entirety.

For the present season, few manufacturers show marked or radical changes, the alterations which make the 1910 product different from the 1909 devices being confined to details of small consequence, and in some cases, of microscopic size. One noticeable change which the year has brought forth, and which might have been reflected by the infinitesimal changes in the actual product, is the action of many prominent manufacturers in buying instead of making their own. This throws the business into the hands of the carbureter specialists. In any list of prominent details, which now show widespread adoption, the first to be mentioned would undoubtedly be the venturi tube, while much attention is being given to multiple nozzles, auxiliary air valves, and improved ease of starting.

Wheeler & Schebler—In the Schebler carbureter, made by Wheeler & Schebler, Indianapolis, Ind., and prominently exhibited at both shows, the venturi shape of strangling tube is not quite as apparent as on some other makes, but the general idea of the venturi tube is carried out, the shape being straight below the nozzle level, narrowed into a small neck just at the nozzle tip, and expanded above in approved form. The concentric float is used on all models as is also the auxiliary air valve. The latter may, however, be had in about any position desired, either vertical or horizontal being regularly supplied, while other angles may be had upon special orders. The design of this is the same in all cases, being a poppet type of valve with a long central sleeve which slides upon a central shaft.

For starting purposes, provision is made to allow of holding the float down, so that gasoline will continue to flow, while, at the same time, the suction will not be strong enough to open the auxiliary air valve. The throttle used differs in detail, being of the butterfly type on Model L, and of the flat, cutoff type in Models E and others.

Stromberg Motor Devices Company—This Chicago concern makes two principle types of carbureters, which, in a word, differ but in the location of the float and minor details. Model A has the float in a chamber separate from the vaporizing chamber, and connected to it by means of a horizontal passage. In Model B, on the other hand, the float is concentric with the vaporizing chamber, and the gasoline flows into the latter through a number of small passages sloping downward, toward a common center, the foot of the standpipe. In both types, the main air enters around the outside of the standpipe, passing upward, through the vaporizing chamber, which is of a slightly modified venturi shape. This modification takes the form of rounding all of the surfaces, so that they present a spherical surface rather than a plain conical one.

In both, too, the auxiliary air is constructed similarly, with the same form of adjustment, and similarly located with regard to the vaporizing chamber, that is offset is a horizontal plane. This auxiliary air inlet has a cone-seated poppet valve, very similar to ordinary engine valves, which valve works against a pair of light springs, both being adjustable. A locking means for each one is provided to retain the proper adjustment, once it is obtained. Fig. 3 shows a section through each one of the two models, designated A and B.

Byrne-Kingston & Company—At this booth is shown the Kingston carbureter, which is of the concentric float, venturi tube type. Around the latter, the main air also enters, the passage for it being concentric with the standpipe. To this air passage, the air is led up from the side by a long pipe shaped like a double elbow. In both Schebler and Stromberg, the needle works from below, from which point it is adjusted for either more or less fuel, but in the Kingston, the needle works down from above, so that it is adjusted from there, just the opposite to the other two. The makers claim that this gives a more accessible adjustment. At the top, too, is found the throttle, which is of the butterfly type, with limits of motion. The passage of the air to the inlet pipe describes a passage of the shape of a channel, that is to say, with two turns, and two only.

Allen Fire Department Supply Company—Chief among the distinguishing features of the Allen carbureter, made by this Providence firm, is the throttle. This differs from the conventional in that it is neither of the butterfly, nor of the piston type, these being the two ordinary ones. It consists of a long slide, semi-circular in section, the flat upper surface forming the diameter of the circle. In the other direction, this is pierced by a circular hole, corresponding to the circular pipe to the engine. By sliding the throttle along on its ways, the hole in it may be made to register with the inlet pipe hole, which corre-

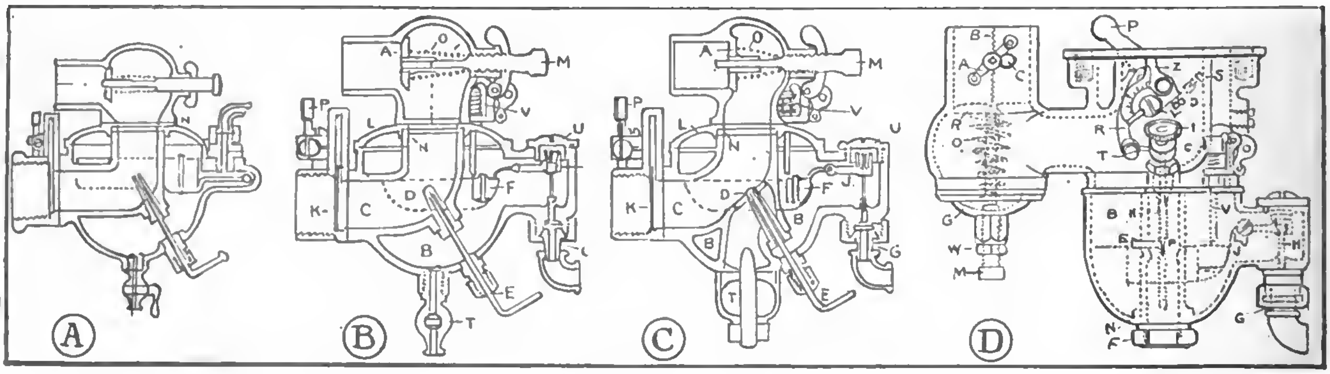

Fig. 2—Schebler carbureters A, B, C, and D, in section

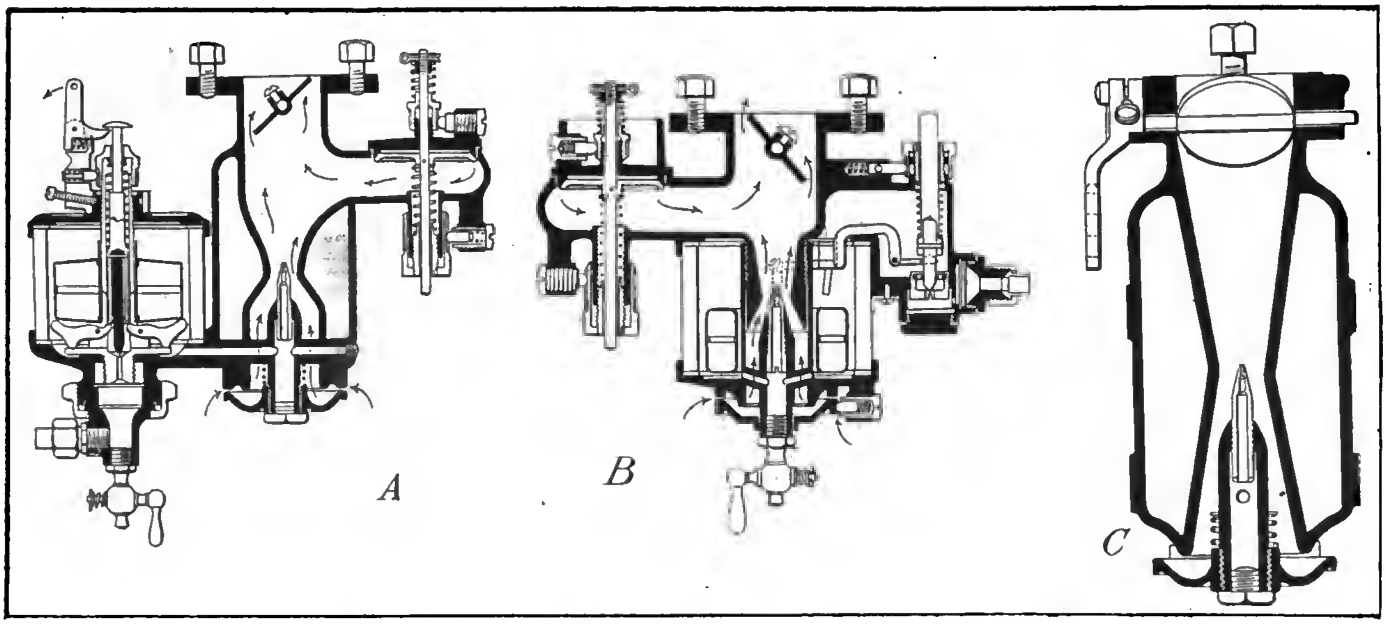

Fig. 3—Sections through Stromberg carbureters A and B. C is a venturi tube of different section

sponds to a wide-open throttle. Other positions on each side of this give partially open throttle, according to the position.

To limit the movement, the slide carries at one end a headless set screw, which at the extreme of the movement in that direction hits against the body of the carbureter base, thus limiting the movement that way. By screwing this set screw in or out, the movement is either increased or decreased. At the other end, a screw with a wide flat head which the slide hits against, limits the movement. This, too, is movable, to change the adjustment. The float is concentric with the vaporizing chamber, but the entrance of the fuel is decidedly out of the ordinary.

Instead of entering directly, the gasoline flows into a small vertical standpipe, from which it overflows at the top, as the needle, entering there at an angle, allows. The vaporizing chamber is a straight tube, the air entering at the bottom, passing straight through to the inlet pipe, picking up the gasoline spray in its passage.

Siro Carbureter Company—In external appearance the Siro carbureter, made by the company of the same name, located at Springfield, Mass., looks like the letter U with a circular attachment at the bottom of the letter. The two uprights of the letter are formed by the air inlet and the pipe to the engine, while the circular base attachment is the float chamber. The engine outlet may, however, be made horizontal instead of vertical, in which case the shape becomes more that of a letter L. The float is of spun copper, made in two pieces, carefully soldered, and thoroughly tested to find leaks. The arrangement of the throttle and the mechanically operated air inlet is such that they operate together, that is, when the throttle valve is being opened, the auxiliary air valve is also opening and in the same proportion. The needle is also connected to the throttle and air proportioner, so that any movement of the others will result in a corresponding opening or closing of the gasoline inflow. Despite the interconnection of these three parts, each one may be adjusted separately from the others, so as to obtain the correct air and fuel proportions.

Watres Manufacturing Company—The Duryea carbureter, made and shown by this company, is somewhat on the U shape also, being of what is known as the "puddle" type. The air enters at one end of a curved tube, forming a very flat U, into the center and bottom of which the gasoline enters, and normally lies in a puddle. The air, with the entrained gasoline in finely divided form, flows out at the other end, through the butterfly throttle to the engine inlet pipe. The float is concentric with the central portion of the carbureter body. That is, it is as near concentric as its H shape would allow.

The needle valve is interconnected with the throttle, allowing gasoline to enter according to the opening of the throttle, which in turn varies with the demands of the engine. The needle has a rather unusual spring controlling device, this consisting of a

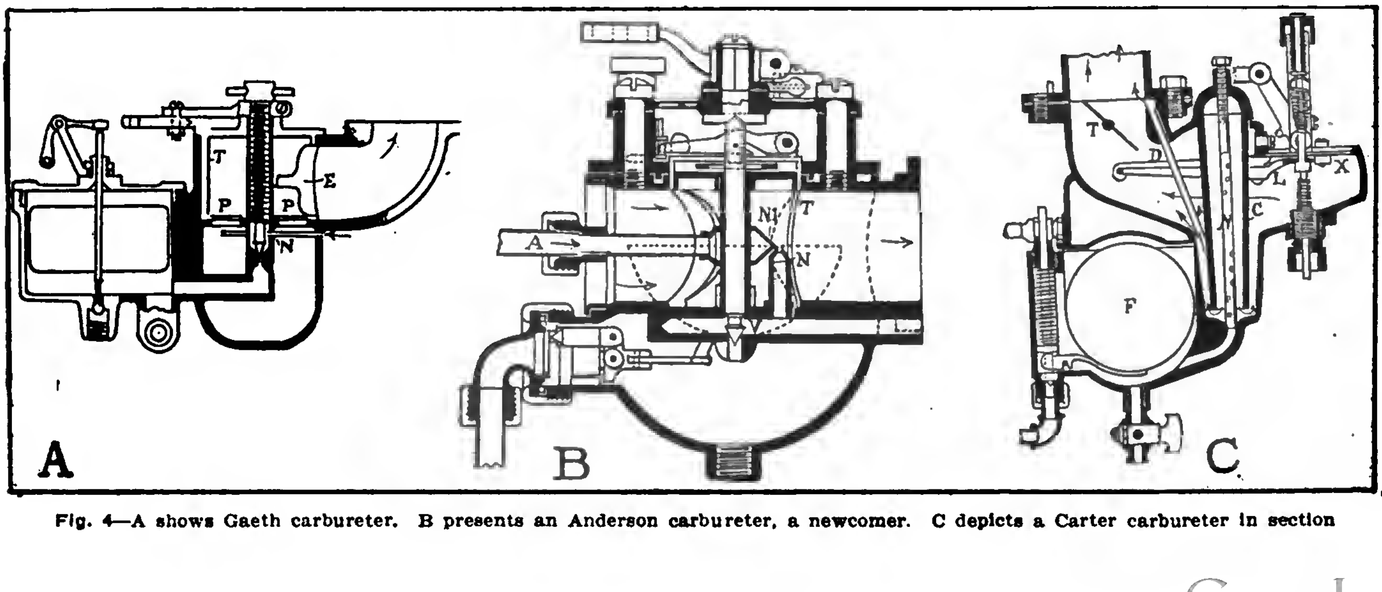

Fig. 4—A shows Gaeth carbureter. B presents an Anderson carbureter, a newcomer. C depicts a Carter carbureter in section

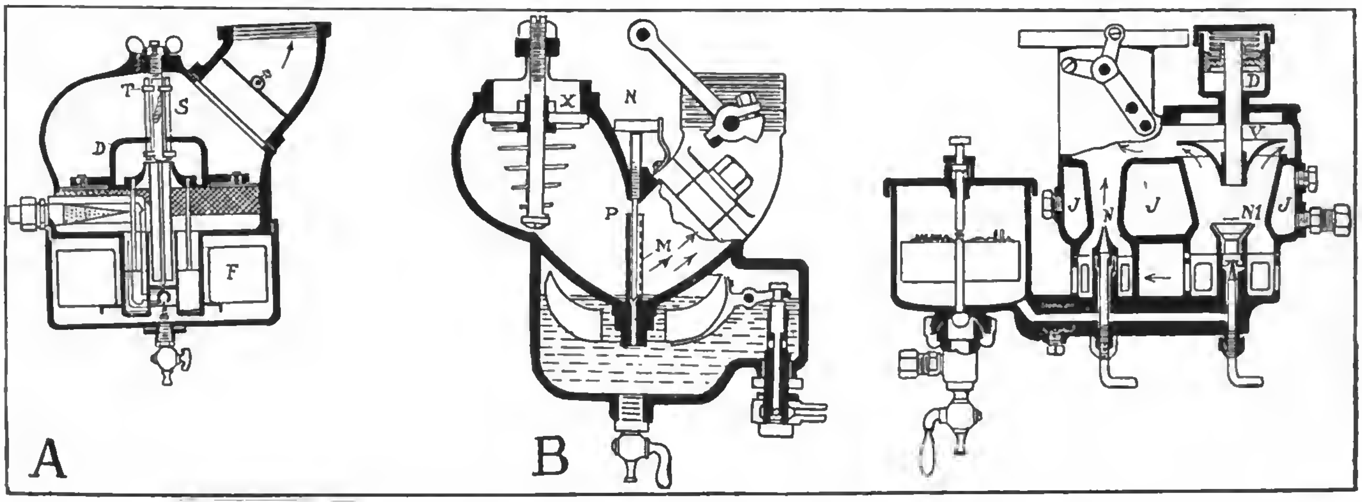

Fig. 5—A is a Duryea vaporizer. B presents the Bennett carbureter. C depicts a Willet carbureter in section

twisted shaft, which is embraced, so to speak, by a pair of parallel arms set so closely together as to move with the turning of the shaft. These arms are pivoted at the top to the end of the spring, so that the motion of the former is opposed by the latter.

Wilcox-Bennett Company—As Fig. 5 shows, the Bennett carbureter, made by this Minneapolis firm, is of the puddle type, the fuel entering at the bottom of a figure U formed by the air inlet and outlet. The nozzle presents some unusual ideas, being not only different, but the point upon which the action is based.

It is a rather high standpipe, with a two-diameter central hole, bored with a series of smaller holes of equal size, one above the other, reaching from the base, close to the bottom of the U, up to the top of the standpipe. Within this the needle valve stem occupies the larger hole, terminating in the needle point and seat at the bottom, where the smaller diameter commences.

Now, as the motor demand is small, the gasoline flows up to say the first hole only. But, with increased demand from the cylinders, more fuel is sucked up, and passes out through several holes, this action continuing until at the full limit of the motor's suction, all of the holes are spouting gasoline out into the vaporizing chamber. A butterfly throttle is used, a semi-concentric float, and a flat-seated air valve, there being no auxiliary air.

Willet Engine & Carbureter Company—Although developed primarily for the two-cycle engine manufactured by this Buffalo firm, this carbureter is placed on the market, and in four-cycle service has been fully as successful as in the two-cycle work, if not more so. This, as shown in Fig. 5, is really two carbureters in one. There is a float chamber which supplies both through a horizontal passage, while each vaporizing chamber has its own air inlet, these being fixed in area by the makers. For ordinary work, at low and medium speeds, the single jet of the first carbureter is the only one to work, the air entering around the base and passing straight upward to the engine.

As the suction increases, however, the piston or cover for the second carbureter is drawn upward by it, thus allowing the second carbureter to get into action. In this there are four nozzles, radiating from the center supply pipe, and all four supply fuel once the vaporizing chamber is put into action. In this, also, the air enters around the base, passes straight upward, then makes one turn into a horizontal passage, connecting it to the main inlet opening, at which latter point the gases from the second vaporizer makes a second turn and join the gases from the first.

Otto Sales Company—This firm imports the Economy carbureter, which is produced in Switzerland by the makers of the Saurer truck, also imported by this firm. The unusual success of the commercial cars fitted with this vaporizing device, winning as they have every contest in which they were entered, has called particular attention to this make and its salient points. It might be described broadly as a multiple jet, clack throttle, non-concentric float type. There are two jets, alike in all respects, set side by side, and fed with fuel through a common horizontal pipe from the float chamber. The clack or flap throttle is pivoted in the center of the vaporizing chamber just above the nozzles. This construction and location allow of the throttle lying over to either side, in which case only the nozzle left uncovered is feeding fuel. With a marked increase in the suction, the flap valve will be pulled up into a central position, when both nozzles will supply fuel. Lest the throttle move quickly back and forth, with consequent uneven action of the engine, a dampening dash pot is provided on the exterior projection of the throttle lever.

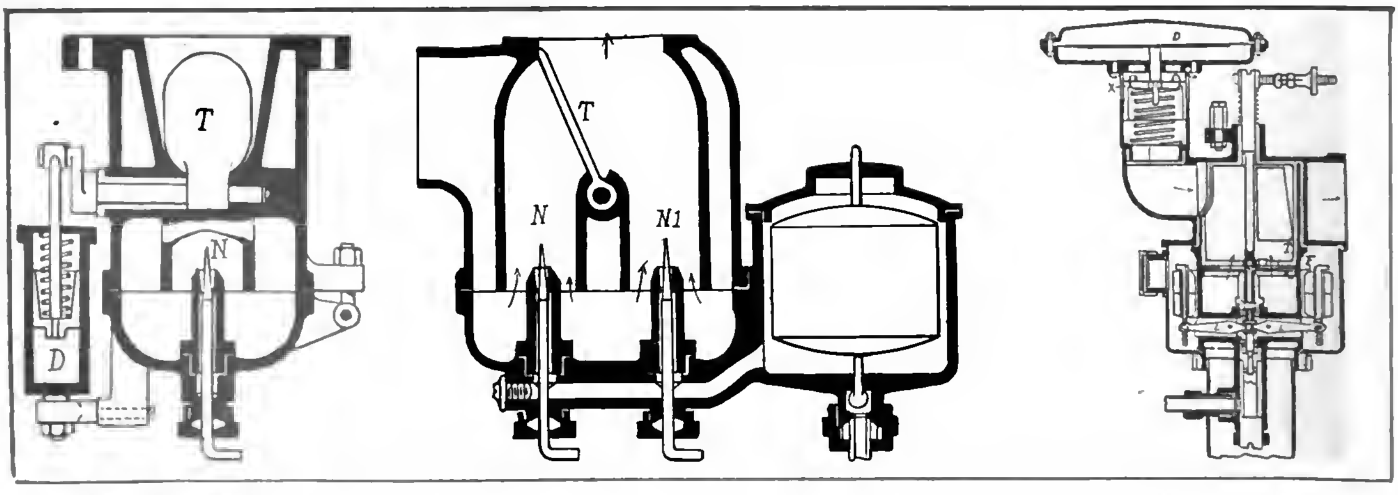

Fig. 6—A and B are sections in two planes of the Economy, a European carbureter. C presents a section through the Chadwick

IN THE FIELD OF ACETYLENE GAS LIGHTING

FAMILIARIZED by many years of service, the acetylene headlight holds its own in the affections of the veteran automobilist, in spite of the wonderful increase in popularity of the various electric forms. Therefore, although the lamp makers almost unanimously show electric lamps, either for combination with the older form or for the exclusive use of the magic current, they do not abate the prominence of the acetylene types. The 1910 lamps show many improvements over the earlier forms. Most of these, it is true, are in external appearance, for the time-tried principles have not been touched. Yet in these days when satisfactory performance is taken almost for granted, appearance is often the only guide.

The most remarkable single feature is the universal adoption of means for reducing the glare of the lamp for city driving. This has been made imperative in many places by traffic ordinances, and many automobilists have been driven to the makeshifts of whitewashing the inside of the door, or pasting brown paper over the glass. Although they secure the results, these are clumsy methods, and the new anti-glare devices, in their many forms, will meet with a hearty reception.

Atwood-Castle Company—Three styles of headlights and a searchlight summarize the acetylene-using product of this company for 1910. In their exterior appearance the feature which immediately attracts the eye is the use of diamond-shaped holes in the upper ventilating hood. These holes, emphasized by moldings stamped in the metal, give the lamps a distinctive touch by which they may easily be recognized on the road.

The first of the styles of headlights may, for purposes of comparison with the others, be designated as the standard. It is of pleasing proportions and neat in appearance. The second will be found more adapted to particular types of cars, being compact, large in diameter and short in length. The third is a popular-priced model. The searchlight has an adjustable gas tip, by means of which the flame may be concentrated directly in the focus of the mirror, for long-distance work, or diffused to give a maximum illumination at close range. All the lamps are constructed of extra heavy gauge material, with all screws placed on the interior, giving a smooth exterior surface for cleaning. Bausch & Lomb and Atwood-Castle short-focus Mangin mirror lenses are used on all models.

Badger Brass Mfg. Co.—The latest development in acetylene lamps for city driving is the "Solar Raydeflector." This is simply a movable gas jet, by means of which the flame may be brought in or out of focus as desired. Normally, of course, the flame is in focus, but for city driving, or when meeting horses on a country road, the jets can be raised slightly. This causes the rays which ordinarily form the long-distance beam to be projected downward so as to strike the road just in front of the car. The only light which continues to be projected directly forward is the direct light from the jet, which does not dazzle any more than that of an ordinary gas jet.

On another Solar product the same result is accomplished in a different way by the use of the Besnard eclipsing system, which is incorporated in the "Solarclipse" headlights. The eclipsing mechanism consists simply of a round, blackened disc on the end of a pivoted arm. The disc can be swung at will down behind the gas jet, between the jet and the parabolic reflector. The effect of this is to cut off the long-distance beam, for although the disc is comparatively small it is close enough to the flame to intercept all the light rays which otherwise would strike the mirror. On looking into one of these lamps with the disc down, only the acetylene flame can be seen against a black background.

The "torpedo type" is another recent development. Like the style of body from which it takes its name, it is very simple in appearance. The body and flare are of a single piece of extra heavy hrass. The door is set deep in the front end, the glass being recessed in such a manner that the front reflector, which is formed by part of the door frame, is outside.

R. E. Dietz Company—Novelties are few on the Dietz stand. This company made up its mind several years ago as to the line it desired to carry, and has found no occasion to change. The only important development has been the weeding out of useless patterns and the concentration of all energies on a few which were found to best meet the demands and needs of the public. The Dietz "Majestic" style is a flare-front design of the type which experience has shown to be the most popular.

The makers of the Dietz line have always laid stress on the strength and solidity of their product. Dietz lamps are said to be considerably heavier than others of the same size, and the extra weight is due to the use of heavy gauge sheet brass and brass castings throughout. Thus, although hardly adapted to act as buffers in the case of a collision, as lamps are frequently called upon to do, the Dietz lamps still will not be damaged by the minor mishaps which will always occur.

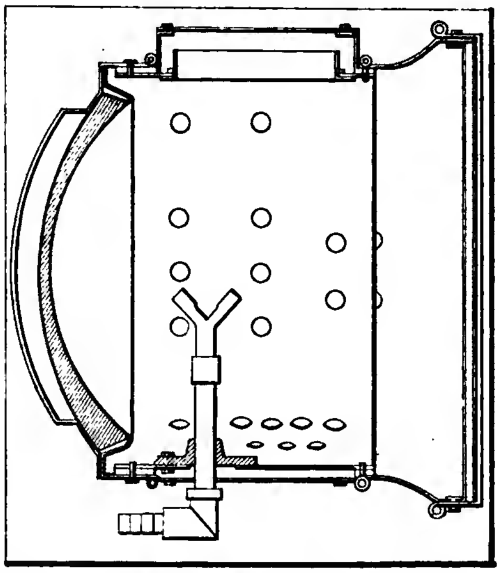

Fig. 1—Section of a Rushmore searchlight type presenting evidences of strength and utility

Edmunds & Jones Mfg. Co.—The E. & J. acetylene headlights are continued in their 1909 forms practically unchanged; they are distinguished by a rather unusual length, which gives them a rakish appearance. The flare fronts are integral with the cylindrical bodies, and the surface as a whole is smooth and easily cleaned. The few parts are strongly riveted together.

Few automobilists have escaped being annoyed by watery gas, even with the best generators. The least excess of water in the generator feed will cause sputtering and uneven action in the lamps, and often will put them out altogether. To overcome this objection to the use of acetylene with generators, the E. & J. Company has brought out a "condensation cup," which is expected to do away with this annoyance. The condensation naturally collects in the lowest part of the tubing connecting the generator with the lamps. The condensation cup is a brass receptacle, to be screwed to the under side of the running-board and provided with a petcock at the bottom. It is connected in the system in such a way that all the gas passes through it. Owing to its position, the cup is much the lowest part of the tubing system, and all the water collects in it.

Gray & Davis—The feature of this exhibit is the new "patent leather" finish, which is the logical outcome of the reaction against excess brass work on other parts of the car. The

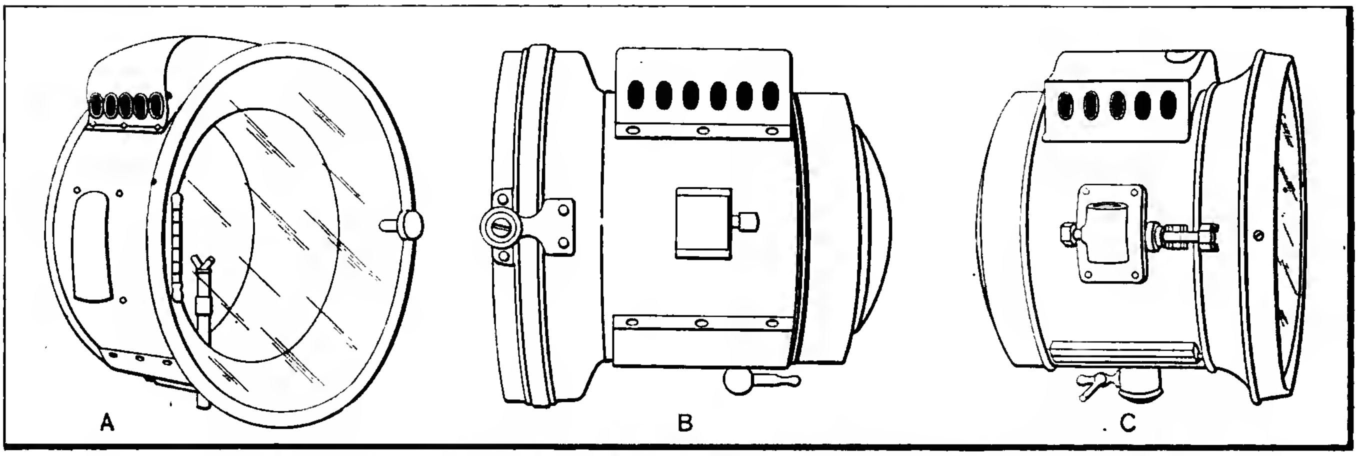

Fig. 2—A presents a Solar lamp; B portrays an E. & J. headlight; C depicts a Dietz type of headlight; all acetylene

"patent leather" gives a metallic lacquer-like lustre, impervious both to heat and moisture. It is made in several combinations with brass and nickel, as well as in the all-black style. The black bodies with the door rims in brass or nickel give an effect that is found especially pleasing, and it is likely that many cars will be seen equipped with these lamps during the coming season. The finish does not need to be polished, and requires no especial care.

The "close coupled" is the latest style in gas headlights, and is particularly adapted to harmonize with the type of body to which it owes its name. The body of the lamp is drawn from sheet brass, and is all one piece up to the door. The brass is carefully selected and annealed. The hood is also in one piece. The mirror and glass front are secured by concealed screws, allowing easy replacing if necessary. The lens mirrors are made of the best imported white glass, carefully annealed, ground and silvered to give the best results. In shape the "close coupled" is unusually short, and the hood runs into the front flare in a distinctive fashion.

Apart from its looks, this type is said to have distinct structural and optical advantages over the longer forms. There is less space horizontally, and therefore no useless currents of air to make the flame flicker. On the other hand, there is more air vertically, where it is needed to carry off the heat, and there is always a sufficient volume of air inside the lamp to give a healthy white flame.

C. M. Hall Company—The headlights of this company are another example of one-piece construction. The bodies are 20-gauge sheet brass, to secure the maximum strength and solidity. The feature of the exhibit is the lamp called the "New Yorker," because it is especially adapted to comply with the traffic regulations of that city. It has a combination gas and electric burner, the gas jet and the electric bulb being arranged on the ends of a Y-shaped brass casting. The "Y" is pivoted at the bottom of the lamp, so that by means of its exterior projection it can be swung to bring either the jet or the bulb into the focus of the mirror.

Rushmore Dynamo Works—The most important development in the 1910 line of this company is the adoption as standard of the "multiplex" door. This door consists of a number of vertical lens strips, the front sides of which are ground to a convex curvature. The effect of these lenses is to spread the light out in a horizontal plane. When the beam from the lamp is cast on a wall the illuminated area takes the form of an ellipse with the longer axis horizontal. All the light is thus thrown on the ground, without wasting any on the sky or the front axle of the car. It has a further tendency to project in the right direction, the light coming directly from the front of the jet.

These lamps will greatly increase the security and peace of mind of pedestrians who happen to meet cars to which they are attached, as the light is kept low down and below the level of the eyes of a person standing within dazzling distance of the lamp. Another advantage is that they overcome flickering, even at high speeds. Their popularity is already so great that it has been found necessary at the Rushmore factory to install additional machinery for grinding the multiplex lenses.

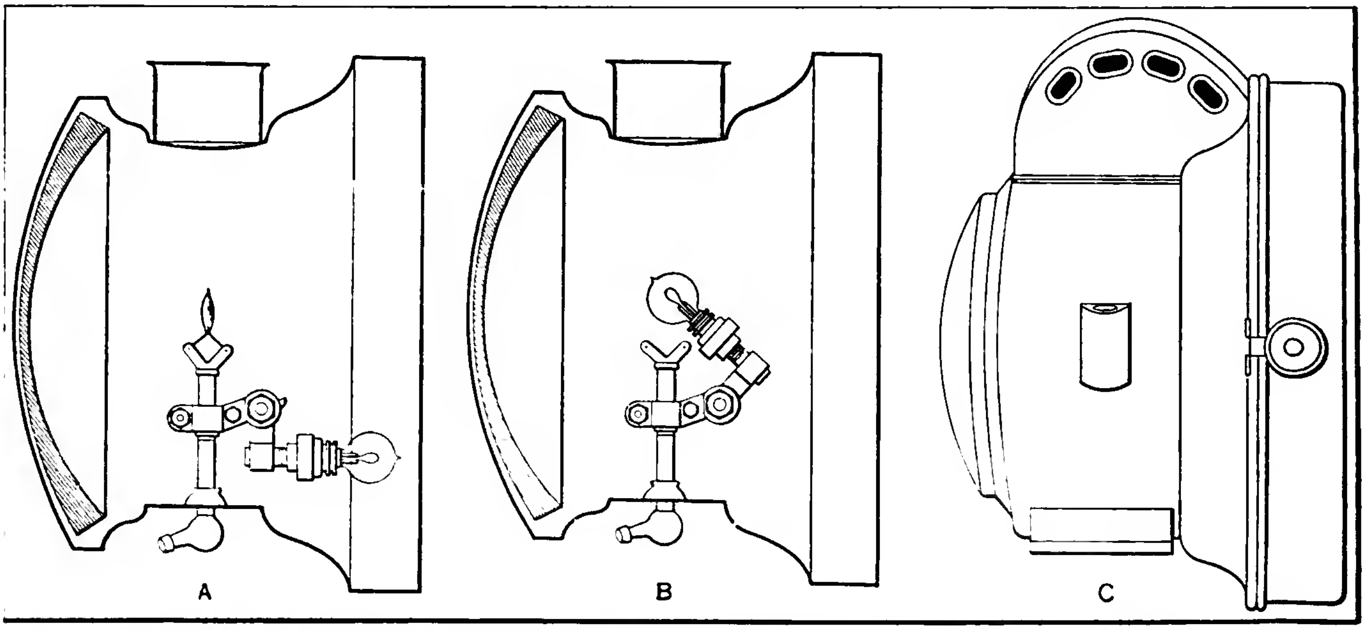

Fig. 3—A depicts a Gray & Davis lamp adjusted for acetylene; B portrays the same lamp ready for electric lighting, and C shows the exterior of the same lamp

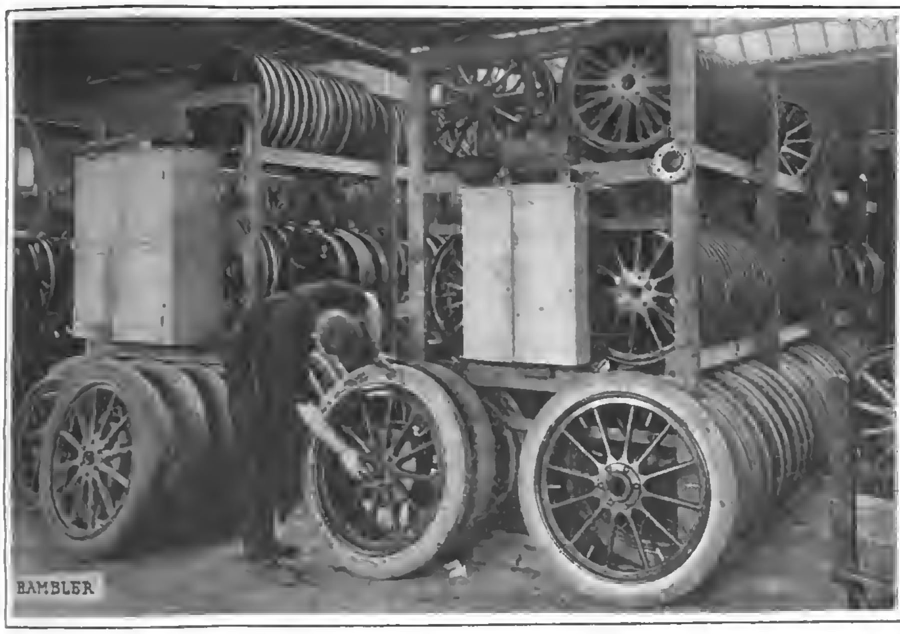

WHEELS, RIMS AND TIRES

AUTOING under pleasurable conditions or on a basis of profit depends more upon tires, perhaps, than upon any other division of the units which comprise cars. Pneumatic tires, while they swallow up road inequalities if they are small, have a further use in that they cushion shock when the inequalities surmount to and assume the proportions of obstructions. In addition to the duties as above indicated, pneumatic tires possess traction far in excess of the tractive ability of steel tires.

In recent times, the tendency has been in the direction of increasing diameter and section of tires in relation to the weight put upon them. It has been determined that the tires should be capable of sustaining the whole load when they are normally inflated, under conditions which will show but slight deformation of the tire section at the point of road contact. If, when a tire is inflated, it still shows a considerable deformation, it is then assured that the tire is not large enough for the work it will have to do, and the life of the same will be relatively short. Life in a tire is almost independent of the quality of the same, if the size selected is below the needs of the occasion. In other words, the difference in life between the best tire made and the most inferior product obtainable will be but slight in the presence of excess flexure.

There is one other lesson to be learned from this: autoists must keep their tires fully inflated; they must pump up to some definite right pressure. This cannot be done haphazard in the absence of a gauge for use in determining the pressure, and be sure that the condition will be right. The ordinary way is to pump (using a flimsy pretext for a pump) until the pumper is tired, give the tire a kick, say it is all right, and let it go. Under these conditions tire life will be short.

WISDOM OF SELECTION ADEQUATELY PORTRAYED

Notwithstanding the considerable cost to makers of automobiles, which is incurred in the adaptation of relatively large tires to their cars, they have elected to suffer a loss of profit in the interest of stability, preferring to deliver satisfaction with automobiles on the ground that satisfied customers expand sales out of all proportion to the cost of selling.

The exhibits this year included a wide variety of anti-skids, non-skids, and other ingenious treads which serve as a protection to the carcass. In the construction of the tires, machine processes are finding a wide use, but the fabric is probably not different from that which has obtained for several years. This fabric comprises from six to ten plies of cotton duck, which is said to be a sea island cotton, and it is "frictioned" before it is laid up. The number of plies vary from six with probably 14-ounce duck, to ten with probably 8-ounce duck. The inner ply is frictioned on one side only in order that the tube will not adhere to the inner surface. The process of frictioning is conducted with a view to coating the duck with a layer of rubber, and this frictioning is done on both sides of the respective plies, excepting the inner ply as before stated. There are a wide variety of details which might be discussed profitably, as they relate to the manufacture of tires, but these are matters which are capably disposed of in the plants of the makers, and there are but two interesting points beyond, i.e., (*a*) the selection of sufficiently large tires for the work to be done, (*b*) the proper inflation of the tires in service.

Hartford Rubber Works—As a non-skid leader, the wire-grip anti-skid tires of this make are attracting a good deal of notice, and the regular line of Dunlop clinchers and quick detachable tires are holding the conspicuous position to which they are entitled in view of the service rendered, autoists having taken kindly to them from the start.

Swinehart Rubber Company—The well-known solid tires of this make, in the regular Swinehart shape, are sustaining the Swinehart reputation, and at the exhibit the clincher truck tires and demountable rims occupied a position of prominence, while the cellular tires for taxicabs, touring cars, and light delivery wagons, represented the Swinehart idea in these fields of commercial activity.

Dayton Rubber Manufacturing Company—The Dayton airless tire is shown this year substantially as before, with the exception that detail structural changes have been made as experience seems to have dictated, particularly in relation to the treads which best serve, considering the respective duties to which these tires are assigned. For 1910 the Dayton line will include a double grip non-skid tire, which shows a flat corrugated tread, with diagonal depressions about one inch apart.

Republic Rubber Company — Referring to Fig. 4 B, the staggard tread is the special feature of Republic tires, and it will be remembered that the Republic company was one of the first to introduce these forms of non-skid treads. It is claimed for this particular shape of the non-skid portions that they are efficient in resisting

Fig. 1—Depicts Firestone tire for non-skid work

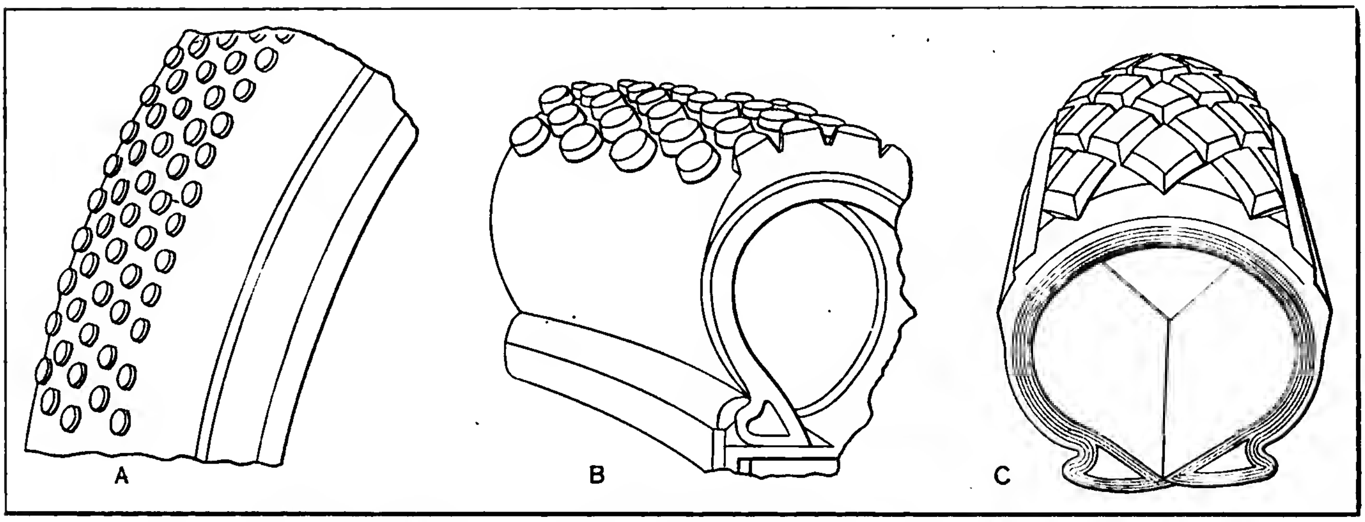

Fig. 2—(A) Shows the Calman non-skid, (B) Presents the Diamond non-skid, (C) Depicts the Ajax non-skid

skidding, but that they do not consume power to anything like the extent which obtains under certain conditions. The elongated oval stud offers a wide surface in the lateral plane, and at the same time permits the tire to swallow road inequalities without introducing a considerable amount of fabric resistance.

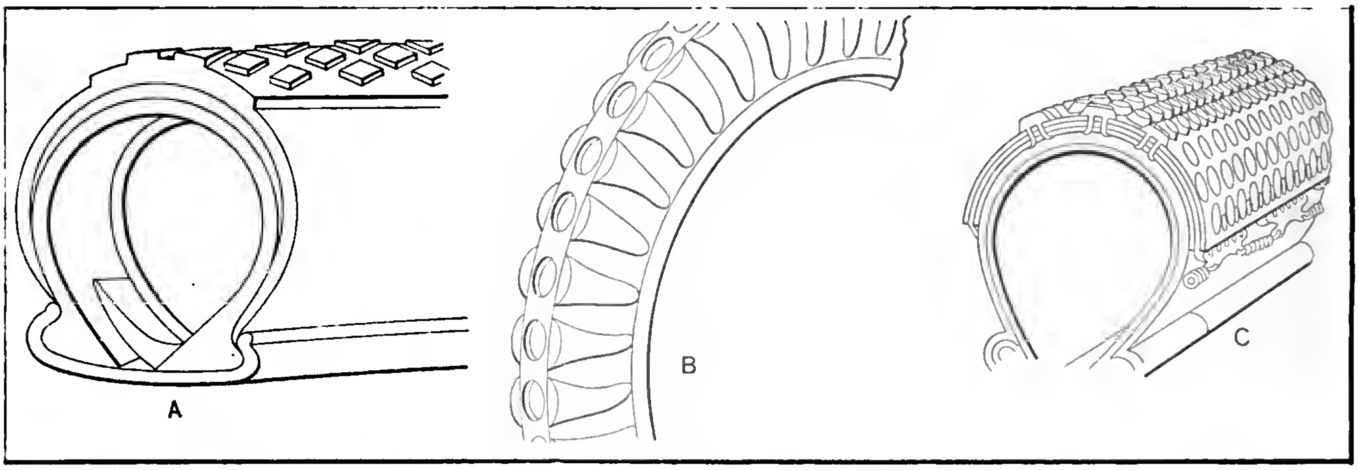

Fig. 3—(A) Indicates the Empire non-skid, (B) Shows the Kempshall non-skid, (C) Presents the Woodworth adjustable tread

Rutherford Rubber Company—This is the concern which makes Sterling tires and tubes. The company claims that it employed a special pre-cure of the rubber adjacent to the bead, and that this process has the virtue of resisting rim cutting to so marked a degree that tire depreciation from this quarter is eliminated. The company also manufactures solid tires for carriages, which are made of a tough interwoven knotty mass of rubber. The Sterling inner tube is distinguished by its blue color.

G & J Tire Company—This line comprises clincher, Dunlop, and quick-detachable casings, and a line of inner tubes which are now so well known among autoists of discrimination as not to demand lauding. Both the round and Bailey treads are used on the three types which are made by this company, and it will

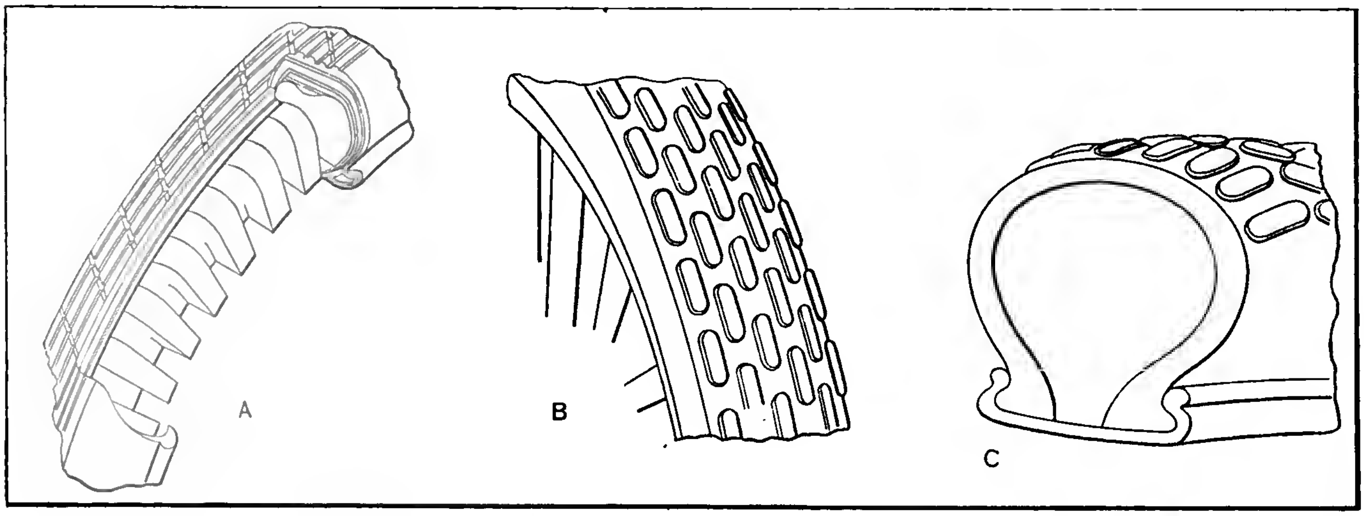

Fig. 4—(A) Depicts the Dayton airless tire, (B) Presents the Republic staggard tread, (C) Shows the Morgan & Wright non-skid

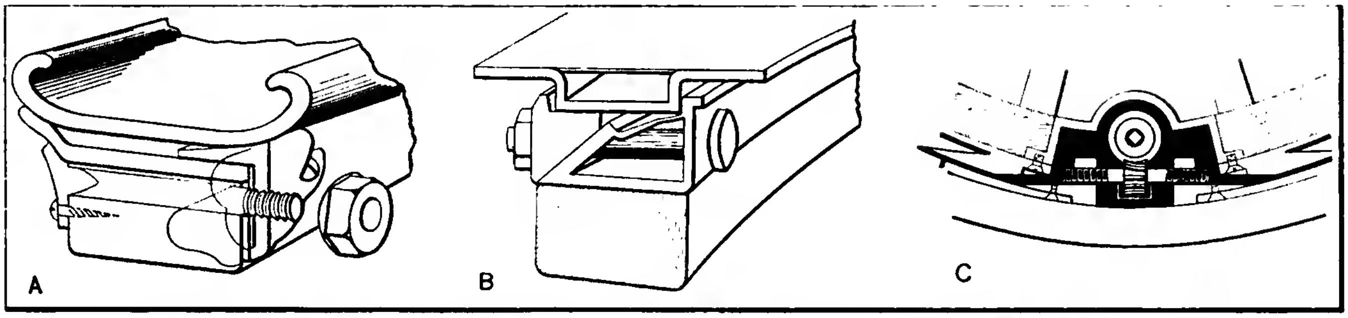

Fig. 5—(A) Is a section of a Diamond demountable rim, (B) Represents a section of a Fisk demountable rim, (C) Depicts the mechanism placed to lock Howard demountable rims

be remembered also that the industry includes a line of motor sundries consisting of tire sleeves, rubber axle bumpers, etc.

Michelin Tire Company—As per the custom of this well-known concern, its exhibit took on the atmosphere of a university, the idea being educational to a marked degree. The Michelin anti-skid tires occupied a prominent place, and they were admired, partly because the anti-skid feature is an integral part of the tire rather than an attachment, the tread proper being made of leather. In the leather tread, three to five rows of steel rivets are incorporated, the steel being mild in its characteristic,

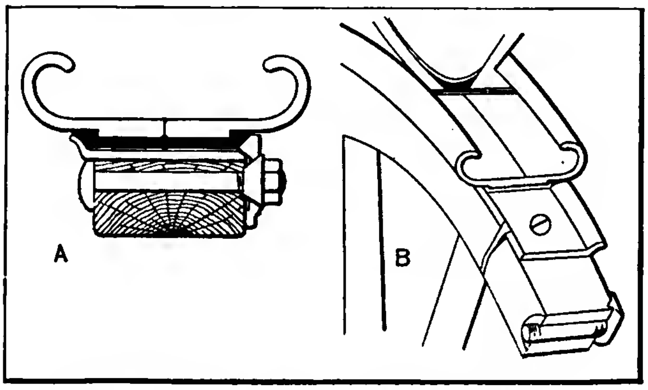

Fig. 6—Nadall combination demountable and detachable rim

hence soft, whereas the novice would expect to find the hardest grade of tool steel, hoping perchance that its hardness would accentuate its wearing qualities. A new idea is the Michelin valve spreader which holds the bead of the envelope firmly.

Pennsylvania Rubber Company—The rubber-wrapped tread and flat tread clincher tires of the Pennsylvania make, showed improvement by way of a tufted wire tread, securely held to the body of the tire by a specially woven fabric impregnated with a compound which the company claims has more than the usual merit, the composition of which is not stated. It is in winter service that these tires show up best, and autosists who ride Pennsylvanias are wont to put forward the pleasing contention that inclemency of weather is no longer a factor in view of the non-skid qualities of these tires.

Empire Tire Company—It is known by the checker tread as shown in Fig. 3 A in which it will be observed that a tread stripped with diamond-like embossed figures holds the position of road contact responsibility, and from indications to be seen it is not an excess when it is said that the result obtained was in keeping with the best requirement.

Goodyear Tire & Rubber Company—In addition to the Bailey non-skid tire, a diamond shape heavy tourist type of tire is also in the Goodrich line, and is made in all the usual sizes. This tire is recommended by its maker for use under the most severe conditions, as in taxicab work, and for big limousines. The Goodrich Universal Q.D. rim is as popular as ever, and was one of the particular attractions at the Goodrich stand.

Diamond Rubber Company—Referring to Fig. 2 B, which shows the Diamond anti-skid, which is a tread of special rubber composition, out of which the anti-skid rivets appear, they being integraled with tread proper. This type of anti-skid tire has made a sufficient name for itself to warrant autoists to depend upon it under the most exacting conditions of service. The Diamond exhibit included its customary wide line of casings and tubes, and it is very likely that the rubber steering wheel exhibited attracted the greatest amount of notice. Besides this steering wheel, the Diamond Rubber Company puts out a line of battery boxes and rubber goods in general.

Ajax-Grieb Rubber Company—The line for this year includes a new Diamond tread tire, as illustrated in Fig. 2 C. It is an all rubber non-skid and guaranteed for 5,000 miles, and attention is particularly called to the design which is shaped to prevent flattening and squeezing into a smooth surface under severe conditions of load. This company offers in addition to this leader, its customary line of smooth and other designs of treads in casings, together with an accompaniment of inner tubes, and it is claimed for Ajax tires that the fabric is selected with particular reference to its mileage guaranteed, and that there are other structural details which will repay investigation.

B. F. Goodrich Company—This company offers this year a variety of sizes of its famous Palmer web tire, which has long been used on electrics, particularly in view of the small tire loss involved, it being the desire of electric vehicle owners to conserve the life of the battery, and obtain the greatest radius of travel per charge. The Goodrich wireless solid tire for motor trucks attracted notice. Then, there is the smooth and Bailey tread Goodrich, and beneath the surface will be found some carefully worked out designs with a view to interchangeability of tires, and other points of more than a little moment, which, to

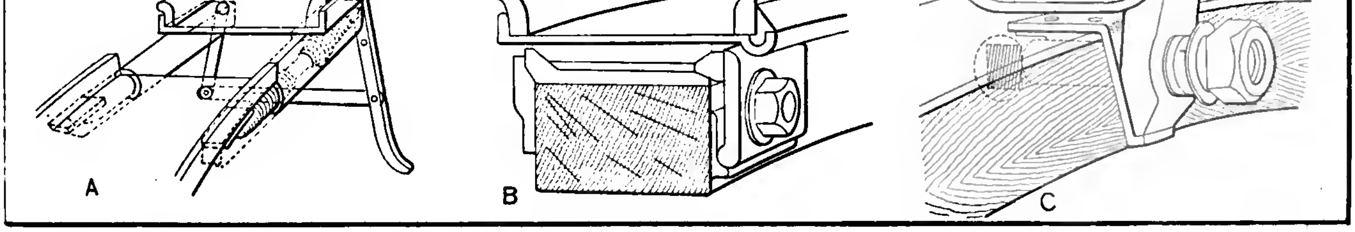

Fig. 7—(A) Shows Goodyear Doolittle demountable rim, (B) Presents the Firestone demountable rim, (C) Offers a section of the Empire demountable rim

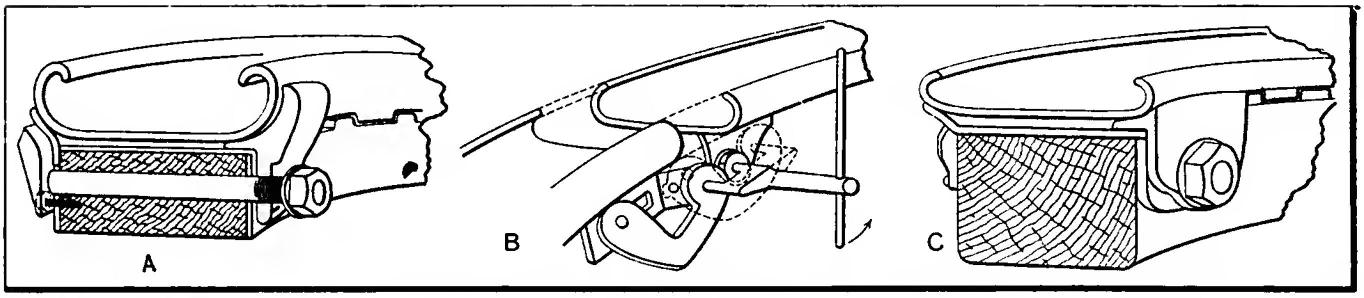

Fig. 8—(A) Is a section of a Michelin demountable rim, (B) Shows method of locking the Universal demountable rim, (C) Offers the Continental demountable rim in section

a considerable extent, are responsible for the Goodrich reputation, which, for uniformity, is well established.

Morgan & Wright—It is called the "Nobby," and looks as shown in C, Fig. 4. It is the new Morgan & Wright non-skid tire. In service this tire has just completed six months, and its trial under the most severe conditions involving what might well be called an abuse test, places it in the front rank of Morgan & Wright achievements. As the illustration clearly sets forth, the rubber projections on the tread are obliquely placed, they being closes the name embossed on the tread diagonally, and the further fact that an efficient non-skid construction resides in the plan. This idea is already well-known to a host of tire users, and the capabilities of Firestone tires are best brought out in severe service. The regular line of Firestones was shown this year, including tubes, regular and odd sizes of casings, and, in fine, everything in tires that prudence dictates. The exhibit held wide interest and the novelty included in having the word "Firestone" on the tread continues to attract.

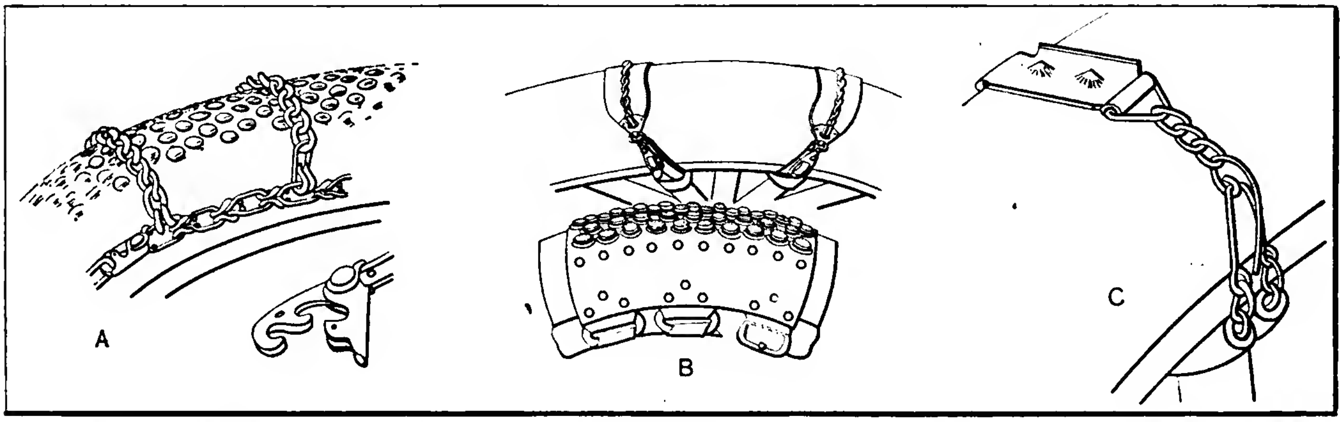

Fig. 9—(A) Portrays a section of the Weed tire chain, (B) Presents the Woodworth boot and chain, (C) Delineates the Travers single chain

of an oval form, and it was one of the main ideas of the company in running its protracted abuse test, to prove that this form and placing of the non-skid projections possesses especial merit. The company's exhibit was complete, including a wide variety of forms of casings, and its well-known line of inner tubes, so aptly displayed as to enable spectators to see at a glance the earmarks of quality.

Firestone Tire & Rubber Company—Referring to Fig. 1, which shows a portion of the tread of the Firestone, and dis-

American Stepney Spare Wheel Company—This line has been expanded to include all regular sizes of wheels as used on automobiles and as a quick-detachable proposition it is looked upon with much favor, especially among users who have tried it out. The Stepney "combination" wheel is the new idea, and by the use of this combination the necessity of carrying more than one wheel is avoided. There are many cars with different diameters of front and rear wheels; the Stepney combination wheel is the answer.

INSTRUMENTS FOR INDICATING DISTANCE

DISTANCES which can be covered and the speeds that are possible of attainment are naturally the strong points of the automobile, and so it happens that the devices which record speed and distance have the first hold on the affections of the automobilist. Apart from the natural pride which the owner and driver take in their machines, the odometer and speedometer are of the utmost usefulness. In many cities magistrates will now take the word of the automobilist as to the reading of a $50 speedometer in preference to the word of a policeman as to the reading of his 50-cent stop watch. Further than this, instruments are now being made which supply automatically an indisputable written record covering every movement of the machine.

For those who adopt the automobile from motives of business economy the odometer is indispensable. All commercial vehicles must be compared on a basis of mileage. The figures, too, give an invaluable check on the outlay for gasoline, lubricating oil and tires. No concern with any pretensions to a decent business organization would attempt to maintain an automobile service, or even a horse service, without keeping an account of the expense per mile. Private owners with a head for figures and statistics are often no less exact.

Auto Improvement Company—No less than fourteen styles and combinations of odometers, speedometers and clocks form the "Ever-Ready" line of this company—not to mention clocks separately and tachometers, equally adapted for use on motor boats and airships. "Ever-Ready" speedometers are operated on the centrifugal principle. They are not affected by climatic conditions, nor are they oversensitive. The hand is claimed to be absolutely steady at any speed from one mile an hour up. In combination with the indicating instrument is used a monocoil steel driving shaft, protected by a brass, steel-lined casing. Each speedometer is given a test of 2,000 miles actual running before it leaves the factory. The speedometers are made with 2 5-8, 3 and 4-inch dials, registering to 50, 60, 70 or 80 miles. They are offered separately, istering to 50, 60, 70 or 80 miles.

Cleveland Speed Indicator Company—This instrument embodies a radical departure from the usual practice in speedometer design. This can perhaps be best explained by saying that it does not indicate the actual speed of the car at any moment, but only the average speed for each one-thirtieth part of a mile. A moment's figuring will reveal, however, that when the car is running 30 miles an hour the averages will be taken over periods of but four seconds each.

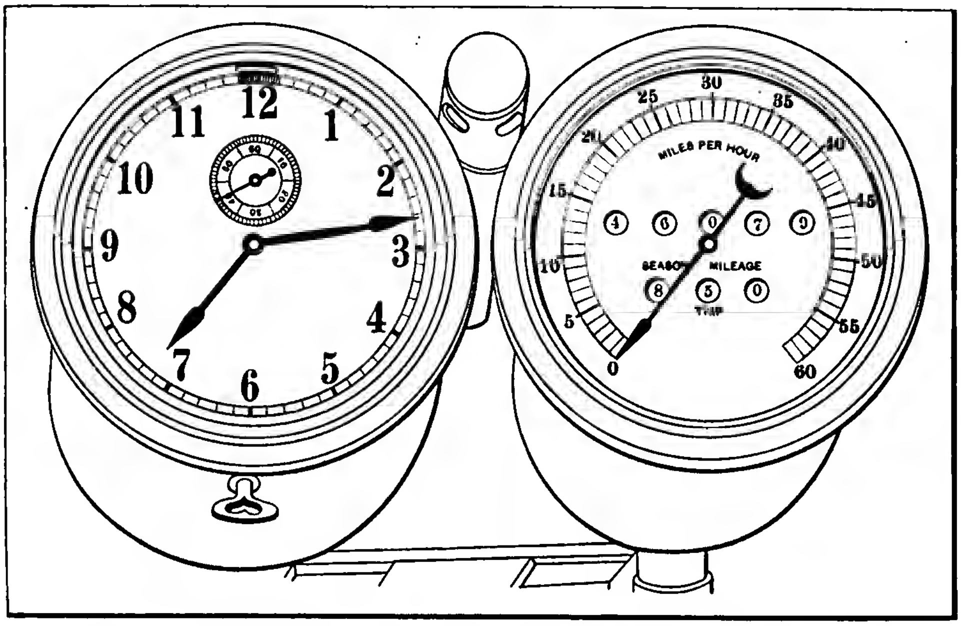

Fig. 1—Stewart multi-polar speedometer with clock giving distance, revolutions and time

Couch & Seely Company—The "Casgrain" speedometer manufactured by this company operates on the principle of liquid friction, and is claimed to have the longest scale of any device on the market. The horizontal cylindrical case of the speedometer contains a concentric cylinder bearing on its circumference the scale figures, and held against rotation by a coil spring. Within this cylinder is a shaft with paddles actuated from the front wheels. The case is filled with a liquid, which

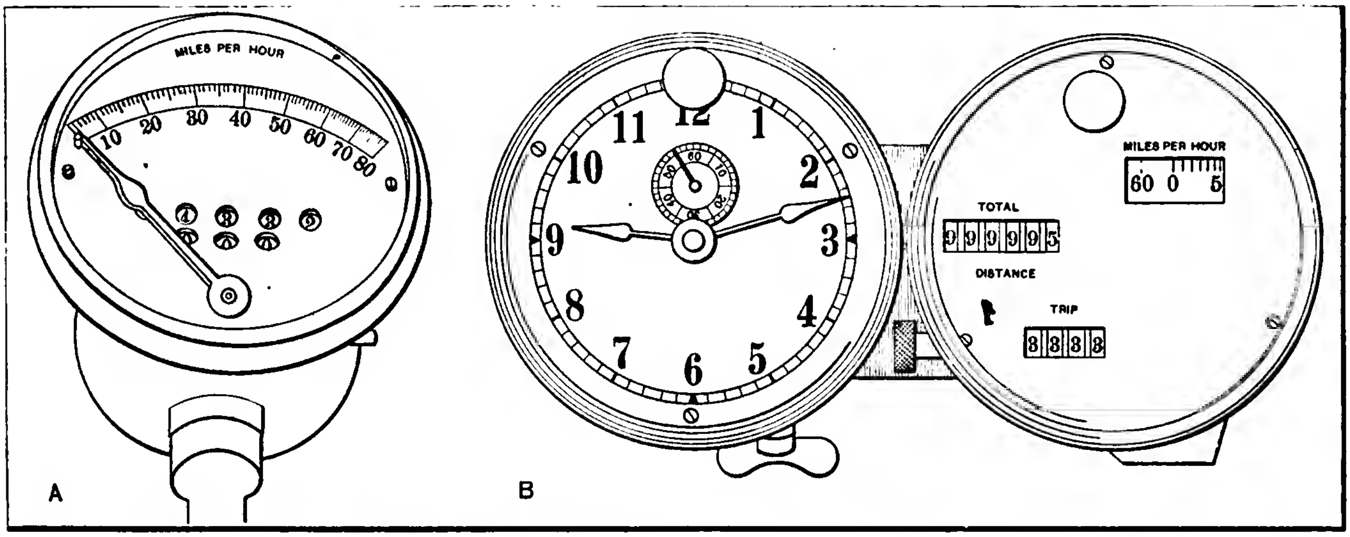

Fig. 2—(A) Presents new Jones speedometer, (B) Shows Warner's magnetic speedometer with clock

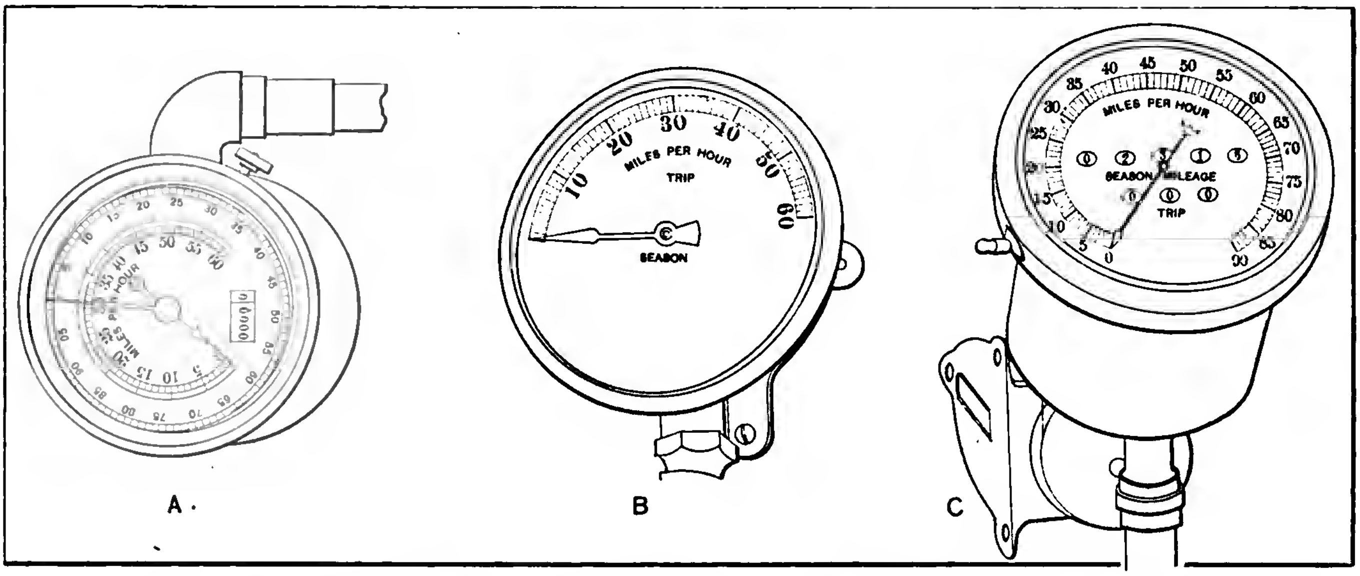

Fig. 3—(A) Offers Hoffecker centrifugal speedometer, (B) Depicts the Autocar speedometer, (C) Presents Stewart Model 19 speedometer

when set in motion by the revolving paddles has a tendency to drag the cylinder carrying the scale around with it. The strength of the drag is naturally in proportion to the speed of the paddle shaft, and the resulting movement of the cylinder causes the scale figures to appear in succession.

Great care has been taken in working out the design. The liquid of course is a non-freezing solution, presumably glycerine, and elaborate productions prevent the possibility of the escape of a single drop of it. The horizontal paddle-shaft is driven by bevel gears, but the drive shaft is made to enter the case considerably above the level of the liquid. Further, the drive shaft is cut with an exterior worm which forces back any liquid which tries to escape up the shaft. The scale is 28 inches long, giving a separate figure for each mile between 1 and 65.

Hoffecker Company—"The steady hand," as featured by this company, is demonstrated in a way which never fails to draw a crowd. One of the speedometers, running at a fairly constant speed, is mounted on a frame moved by a cam action which from time to time gives it a violent jolt. The indicating hand, nevertheless, remains as steady as if only painted on the scale, though moving freely when the speed is varied.

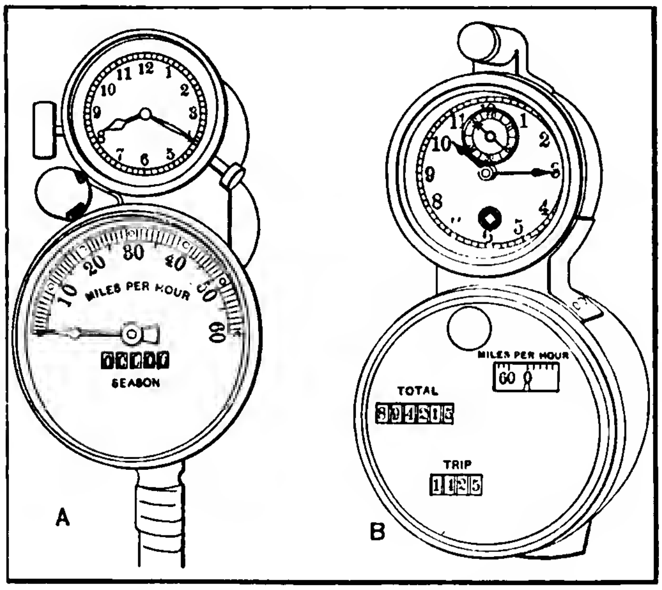

Fig. 5—(A) Illustrates the Ever-Ready reliable Speedometer, (B) Depicts the Warner combination speedometer

As to principle, the Hoffecker is another exponent of the centrifugal type, but incorporates with the usual mechanism a special damping device to check the small variations which arise from jolting of the instrument.

The Hoffecker is made in three sizes, with 3, 3 1-2 and 4-inch dials, scaled to 50, 60 and 90 miles. With the smallest size a separate season and trip odometer of the well-known type is used, but in the larger forms both are incorporated in the body of the instrument, and the trip mileage indicator is of a peculiar form. The mileage is indicated by a hand moving on a scale concentric with that of the speed indicator, either inside or outside of it. The season odometer is of the usual type, with figures showing through a window.

Jones Speedometer Company—The feature of the Jones exhibit which attracts the most attention is the new "Live Map," a sort of animated Blue Book. It consists of a cardboard disc perhaps ten inches in diameter, the rim of which is marked off into sections corresponding to miles on the route which it is desired to follow. Separate discs are used for each route, each disc being for a maximum distance of 100 miles. The route directions are marked off on the rim. The disc is revolved by a connection with the wheels so that points on its circumference pass in turn under a stationary pointer. The pointer always indicates the position of the automobile, and the appropriate directions may be read off the disc.

The device is extremely simple, consisting only of a frame carrying the gearing, with the usual flexible shaft connection, and the removable cardboard disc. The shaft is of sufficient length to permit of the instrument being passed around among the occupants of the car, or it may be hung up on the dash or the seat. About 600 different cards, each representing a maximum of 100 miles, have been prepared by the Touring Club of America, and are listed in the Jones Company's catalog.

Recometre Company—The object of the "Recometre" is to record automatically every movement of the automobile to which it is attached. It contains a tape on which is permanently printed a record of the car, both in motion and at rest, for every minute of the day. If in motion, the distance traveled and the rate of speed are also recorded.

The tape on which the record is made is marked into divisions of about a tenth of an inch, and is unrolled by clock-work at the rate of one division a minute. A line is traced in red ink on the tape by a pen which moves up and down regularly once for every mile the car travels. The result is that a saw-tooth line appears on the tape whenever the car is in motion, and a straight horizontal line as long as the car is at rest. The number of teeth in the saw-tooth lines indicate the number of miles the car has traveled, and the number of minute spaces included in the base of each tooth show the time taken to cover the mile.

The tape, with its record for the past half-hour, is always visible through a glass door in the instrument. It acts as a clock and calendar, for the month, day, hour and minute are pointed out on it by the pen. Each tape lasts one week. The instrument includes a speedometer and a season and trip odometer.

Stewart & Clark Mfg. Co.—The Stewart "Multipolar" speedometer is shown in a number of combinations, both for attachment to the dashboard and for mounting on the special standards introduced by this company. The principle and operation of the instrument differ in no way from the forms already found satisfactory. The principle, of course, is magnetism, the influence of revolving magnets upon a disc held by a spring. The drag upon this disc is in proportion to the speed of the magnets, and the indicating hand is mounted on the upper end of the disc spindle.

The rotor of the instrument driven from the front wheel consists of a ring in which are imbedded four permanent magnets. These are accurately machined from imported tungsten steel, made to special analysis. They are hardened, magnetized, edged and tested before being assembled in the rotor. The central stud on which the rotor revolves is recessed to receive a light spindle on a jewel bearing; the spindle carries a disc of alloy metal having a low resistance, and above this the indicating pointer which appears over the scale. The disc attempts to follow the magnets, but is restrained by a light spring. The indicating elements are extremely light and so have little inertia; the action of the instrument is at once sensitive and steady.

Veeder Mfg. Co.—This company prefers to call its speed indicator a tachometer, although this term is generally accepted as meaning an instrument that reads in revolutions per minute rather than in miles per hour. No matter what name it goes by, the instrument is one of the simplest on the market. The only moving part is a small paddle wheel like that of a centrifugal pump. The casing of the paddle carries a small vertical glass tube, and is filled with a red liquid. When the paddle revolves the liquid is driven more or less completely out of the casing, and is forced to rise in the glass tube. The level to which it rises at once indicates the speed.

Adjustment is possible at any time. As long as the level of the liquid is at zero when the car is at rest, the indications must be correct. If the level should not be at zero, it can be brought to that point by turning a small adjusting nut. Another feature is the use of a double scale, one for high speed and one for low speed. Either of these can be brought into use by means of a valve. One is graduated up to 30 miles an hour, and gives accurate readings at low speed; the other is graduated up to 60 miles an hour for high-speed work. Other combinations can be had as desired.

Warner Instrument Company—Warner "Auto-Meters" are continued in the forms familiar from last season, both in the well-known original shape and in the newer style with a circular face. The mechanism of the two styles are identical. working on the magnetic principle. The indication is by means of a moving cylindrical band, bearing the figures, and a stationary pointer. The band is moved by the magnetic drag from the rotating magnet mounted on the main shaft.

Fig. 6—Jones Live-Map route indicator

The latest development is the new odometer, of which the season and trip faces read to 100,000 and 1,000 miles, respectively, instead of to 10,000 and 100 miles, as is customary. The instrument "de luxe" is a clock and speedometer twin, each with 4 1-2 inch dials, and provided with an electric lighting device by which light is thrown on the interior of the transparent dials. Other forms include the old-style indicator. either separate or with a clock mounted on top, and the new style circular face instrument separate and with superimposed clock. Another feature of the exhibit is the anemometer for aeronautic use, an instrument for measuring the velocity of the wind. When mounted on a aeroplane it is used to indicate the speed at which the machine is passing through the air.

In conclusion, one cannot help remarking on the ingenuity and knowledge of mechanical and physical principles which are displayed, individually and collectively, in the design of the speedometers on exhibition at the various stands. Centrifugal force, magnetism and friction all have their representatives, and in theory all are equally interesting. The working out of the application of the principles, and the arranging of the more or less complicated mechanism within the compass permitted a speedometer, shows mechanical training of a high order. The instruments all appear to be of solid and substantial construction, well balanced and with ample bearing surface.

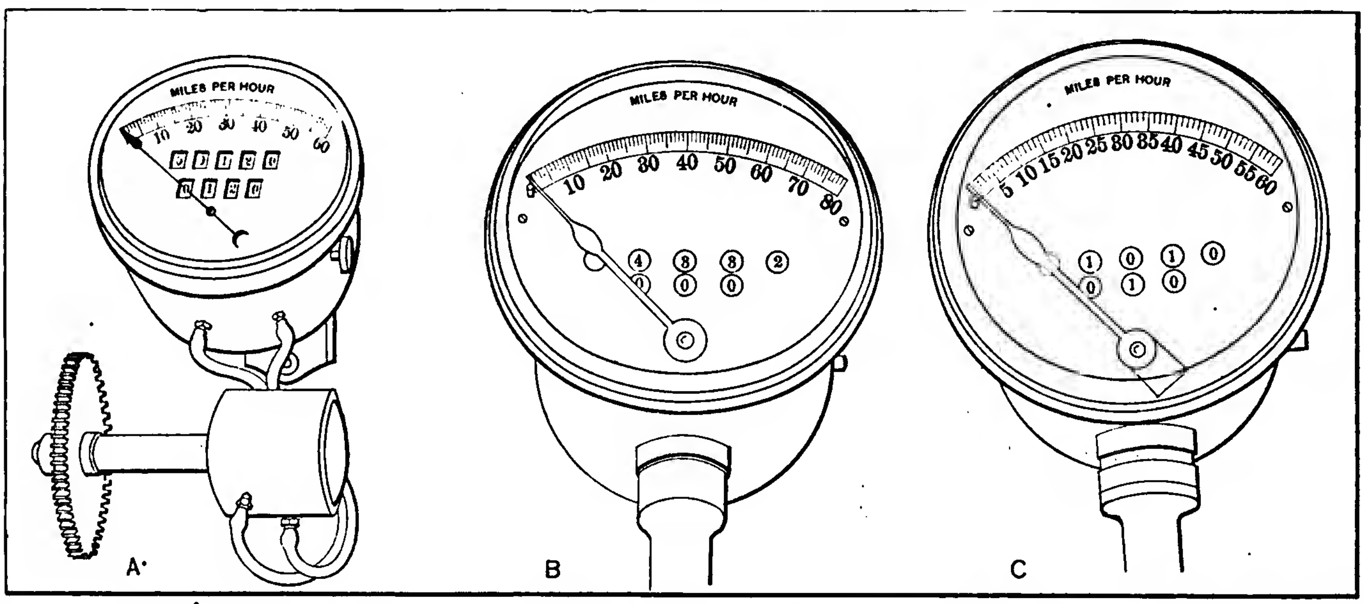

Fig. 4—(A) Offers the new Troy speedometer, (B) Depicts the new Jones speedometer, (C) Presents the Jones Model 19 speedometer

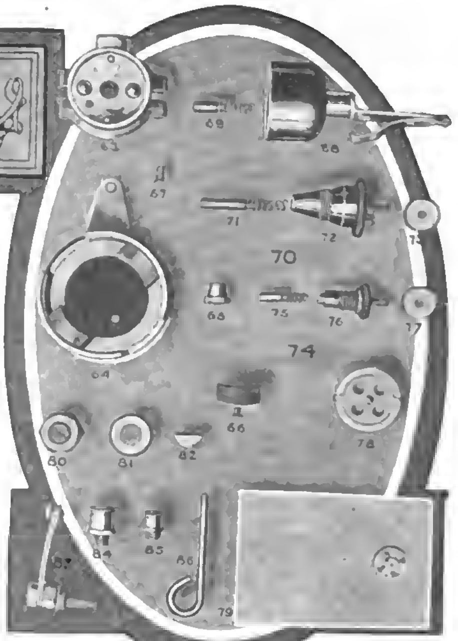
IGNITION METHODS ASSUME DEFINITE FORM



SPARKING equipment as it is to be obtained in the open market may be classified substantially as follows:

(A) High-tension magnetos.
(B) Low-tension magnetos.
(C) Low-tension magnetos with step-up transformers.
(D) High-tension magnetos in dual relation.
(E) Batteries with single coil.
(F) Multi-unit coils.

Battery and coil systems include both storage and dry batteries, and in certain cases (E) a single special coil, in conjunction with a high-tension distributor, is utilized to the exclusion of a multiunit coil. An example of this character of work by Splitdorf will be found in Simplex cars.

Multiunit coils (F) are widely used as supernumerary to magnetos, and these coils are subdivided in turn (a) with master vibrator unit, (b) with a vibrator for each unit; occasional examples of coils without vibrators are to be seen.

Among the ignition systems of competence which are used in automobiles of distinction the following are conspicuous examples:

U & H Master Magneto—Fig. 1 shows the type C B 4 magneto of this make, which is designed for three, four, six and eight-cylinder work, and, according to J. S. Bretz Company, New York, distributor of this magneto, its application is limited to motors with a bore which does not exceed 4 1-2 inches. Other types of U & H magnetos are provided for the several other applications. The illustration is sufficiently comprehensive to limit the need of further discussion, unless to point out that the wire *T*, shown at the interrupter end of the magneto, registers with the timing mechanism, and in the act of timing the whole operation is limited to the simple process of forcing the wire *T* through the registering holes, which may be easily accomplished by rotating the armature until the wire enters.

Pittsfield Spark Coil Company—The magneto as made by this company is depicted in Fig. 2, in which *A* is a section at right angles to the armature shaft and *B* is a section in the plane of the armature shaft cutting its axis. This magneto is of the strictly high-tension type, containing a primary and secondary winding; the windings are stationary.

Witherbee Igniter Company—Referring to Fig. 3 of the Witherbee magneto, *A* is a section at right angles to the armature shaft, and *B* is a section in the plane of the armature shaft cutting its axis. It is claimed for this magneto that it is a generator of current for ignition purposes of such competence that it will work successfully over the wide range represented by merely turning the armature by hand or rotating it at the highest possible speed consistent with motor practice. This product is made at Springfield, Mass.

Remy Electric Company—Referring to *C*, Fig. 3, which is a section of a new Remy magneto (the Remy plant being at Anderson, Ind.), it is shown that the coil is concentric with the armature shaft, flanked by polar extensions, and, taking the section as a whole, it presents an opportunity to study the design and note the character of the work. The Remy company has put out two models for 1910, one of which, type S, is for two, four and six-cylinder cars with high-powered motors.

Splitdorf Laboratory—The 1910 Splitdorf magneto is depicted in section in Fig. 4 A, representing the new low-tension type, with annular type ball bearings at all points, and a very efficient armature winding in a well-designed rotor. The magnetic field comprises six permanent magnets, made of a special grade of magnet steel, properly hardened, and the details throughout are up to the usual Splitdorf standard. The Splitdorf plant is in New York City.

Kokomo Electric Company—The Kingston Magneto as made by this company at Kokomo, Ind., is shown in B. Fig. 4, which is a section through the armature. Annular type ball bearings are used and the mechanical construction throughout is up to a fitting standard. The armature is of the bobbin type, with a high-tension winding, and the condenser is placed concentric with the armature shaft, at the front end.

Apple Electric Company—The Apple, as shown in A Fig. 5; is a direct-current dynamo and differs from a magneto in that the fields are wire-wound rather than with permanent magnets. This type of ignition is used in connection with a battery (storage) and coil. The battery floats on the system, is charged automatically as the demands indicate, and the coil works just in the same way as when a battery, unaided, is employed. This system has done good service for several years, and in many cases electric lights are run off of the dynamo; just now, when electric lighting is on the increase, it should be in brisk demand. A constant speed of the dynamo is brought about through the use of a conical pulley on the dynamo and means (a governor) for sliding the conical faces to regulate speed of the dynamo as the speed of the motor changes.

United Manufacturing Company—With a master vibrator unit, the Connecticut coil, as depicted in Fig. 6 A, represents a system which has taken a high rank among motorists. The box

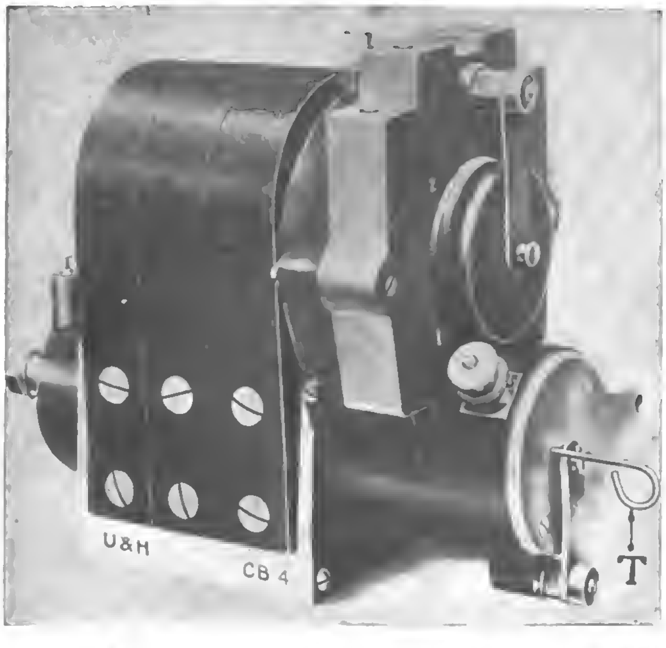


Fig. 1—U & H magneto, showing the timing wire T in the registering holes, this being the only adjustment required

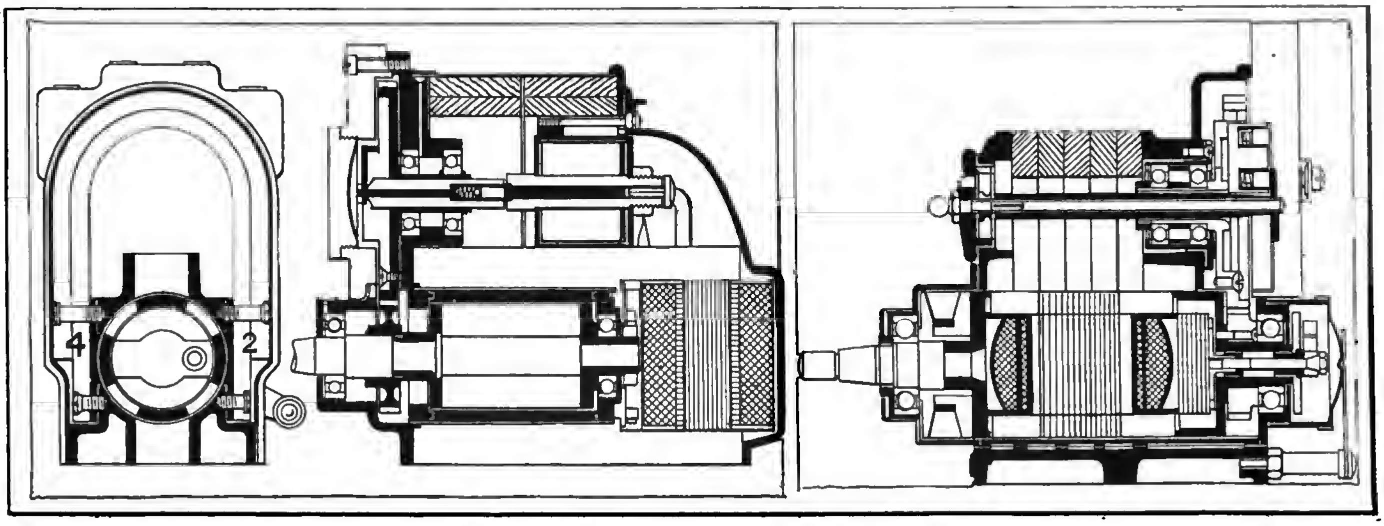

Fig. 2—(A) Section of Pittsfield magneto at right angles to armature shaft. (B) Section of magneto in the plane of the armature shaft. (C) Section of Herz magneto

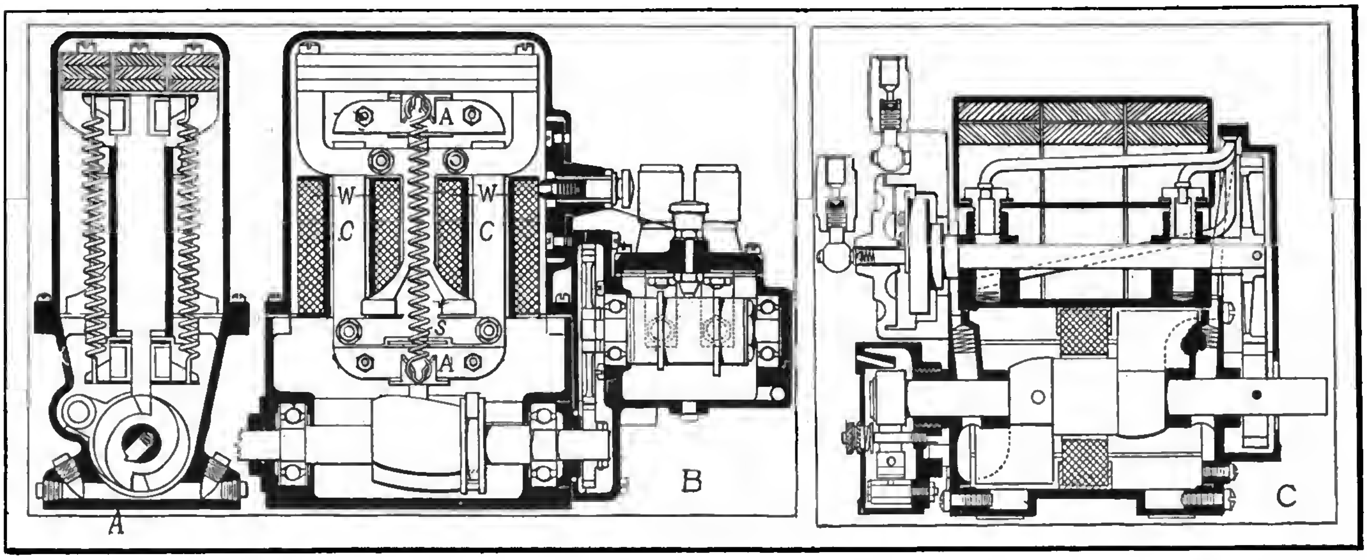

Fig. 3—(A) Section of Witherbee magneto at right angles to armature shaft. (B) Section of magneto in plane of armature shaft. (C) Section of new Remy magneto

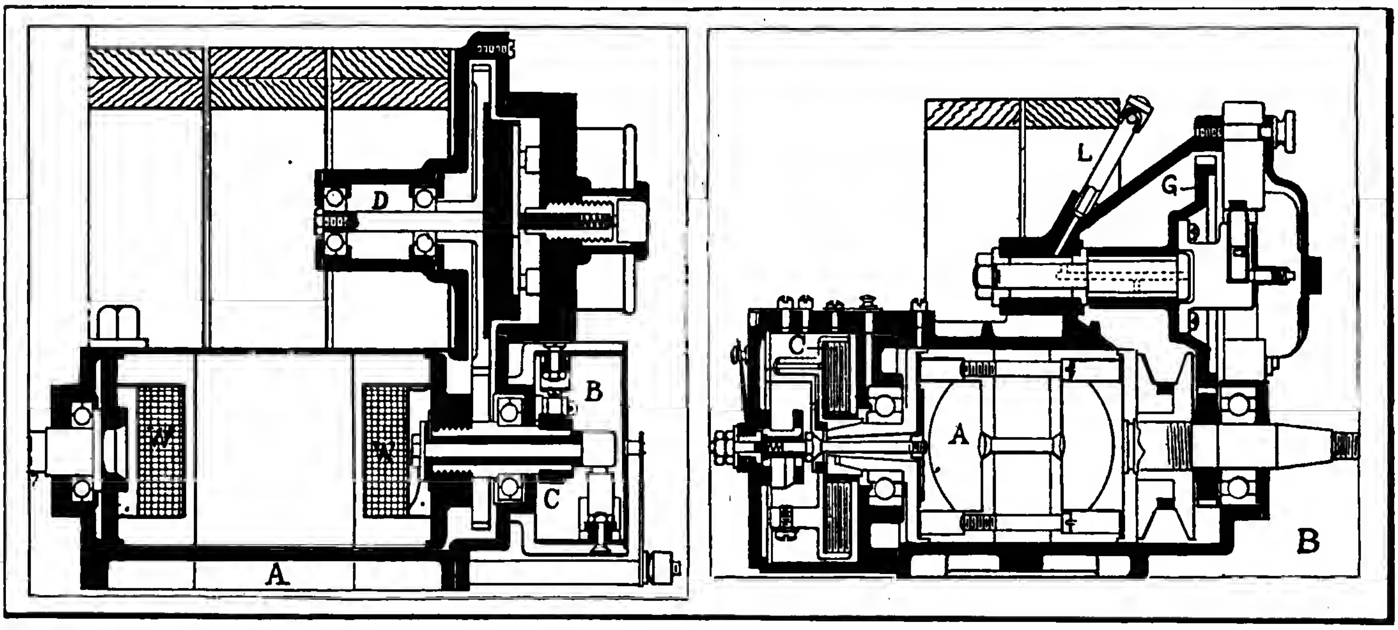

Fig. 4—(A) Section of Splitdorf magneto, showing annular ball bearings for mounting, (B) Section of new Kingston magneto

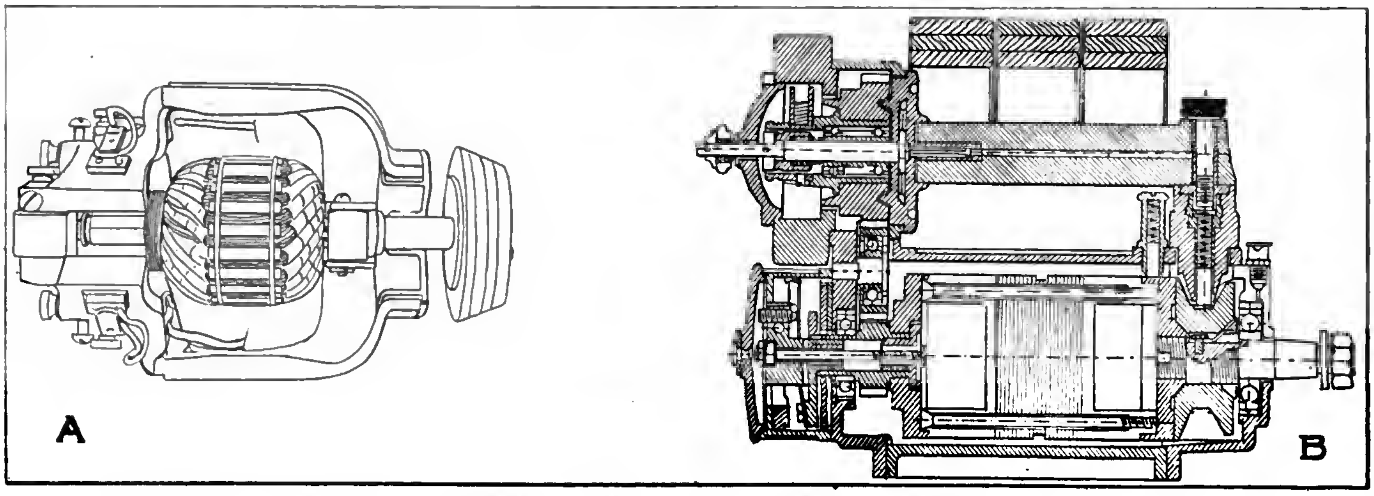

Fig. 5—(A) Apple dynamo in section, the same being used for ignition and lighting. (B) Neimellor magneto in section

holds five units, four of which are coils and the fifth is the master vibrator unit. All adjustments are made on the master vibrator, and, as will be readily appreciated, the spark will be the same in strength and potential difference in all cylinders. This system is used with or without a magneto.

Bosch Magneto Company—This well-known make of magneto is made in all high-tension types, and the illustration, Fig. 7, shows the connections of the "dual" system. In this system the magneto is electrically connected with a step-up transformer and it is optional with the user to run on the magneto or coil. The magneto is so designed that it serves as an interrupter for the battery circuit when the coil is in use, and the latter is equipped with an interrupter to "start on the spark."

Electric Storage Battery Company—Maker of the "Exide" battery; in ignition work it is delivered in two forms; one in the conventional way with the usual number of cells in series enclosed in a polished wooden case, charged complete, ready for service, and the other comprises the regular ignition battery with an emergency battery in the same case. The home of the "Exide" is Philadelphia, Pa.

National Carbon Company—This company makes the well-known dry battery known as the Columbia, and, having experimented along lines to develop the battery for use in ignition work, has brought it up to a high state of perfection; it is made in all regular sizes; headquarters are at Cleveland, Ohio.

Vesta Accumulator Company—This company presented a full line of electric lamps and headlights, as well as batteries for all purposes, as sparking, lighting, etc.

Motsinger Device Company—The direct-current magneto of this make was the novelty and a new machine for primary ignition service attracted more than the usual notice.

Atwater Kent Manufacturing Company—A simplified form of the sparker generator of this make was shown and attracted the usual notice. The Kent idea is one good spark at the right time, and it has been shown that the battery is conserved if the remaining useless sparks are dispensed with. The unisparker was also on hand, it being a simplified form of the spark generator, consisting of a contact maker, distributer, non-vibrating-coil, condenser and switch.

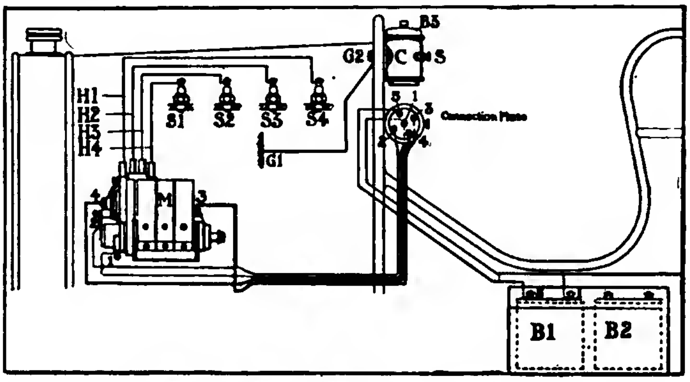

Fig. 7—Bosch dual ignition system in diagrammatic form

Emil Grossman—Of "Redhead" spark plug fame; this grade of spark plug has attracted a considerable amount of notice due to the use of porcelain which stands a high electrostatic strain and is impervious to moisture or lubricating oil. The plugs were shown both wth porcelain and mica, and the "redhead" is branded on every spark plug of this make; it is the Grossman sign of spark plug quality to which patrons subscribe.

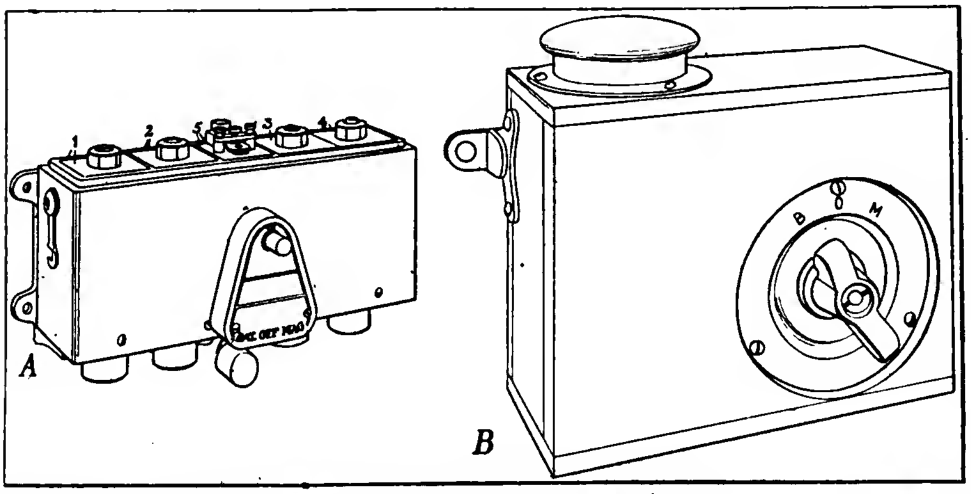

Fig. 6—(A) Connecticut coil system, with unit coils and master vibrator unit. (B) U. & H. coil as used with magnetos of the same make

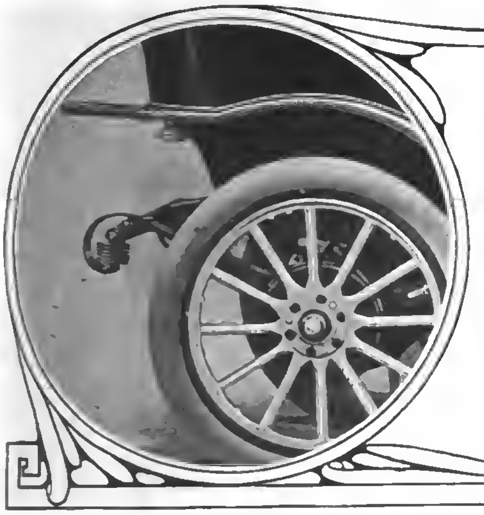
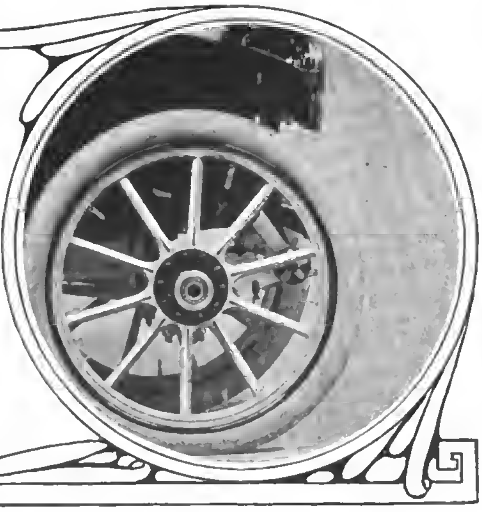
Union Battery Company—This company exhibited dry cells of all sizes, some of them especially designed for ignition work. In addition to cells, there was a line of flash lights. It is claimed for the Union make of dry cells that they are of high ampere output and deteriorate but slowly, if at all. The No. 6 cells have an output, each, of 34 amperes of current at 1.6 volts electromotive force. These batteries are made at Belleville, N. J.

Willard Storage Battery Company—This old and well-known maker of storage batteries offered a line of sparking batteries, some of which are large enough for electric lighting as well.

(*Continued next week.*)



WIDE DISPLAY OF SHOCK ABSORBERS



COMFORT to the occupants of the vehicle is the main idea of all shock absorbers, and similar devices, although it does not require any very complicated reasoning to show that the same arrangement which makes riding more comfortable, reduces the wear and tear on the chassis parts to a minimum. This latter, in a word, spells economy of maintenance, since repair parts and the cost of installing them are properly included in the maintenance cost.

However, their real reason for existence is the smoothing out of rough roads, the other reason being an afterthought. In this respect the value of the shock absorber depends entirely upon the extent to which it absorbs shocks—the greater extent to which this is done, the greater the value of the device. As a whole, they may be divided into three great main classes—the one depending upon non-compressibility of fluids; the second, frictional contact between two or more surfaces in contact; and, third, coil and other springs. Into one or the other of these three main classes, all forms of shock absorbers, or road-smoothers as they have been called, may be accurately divided.

Ernst Flentje—Coming in the first class, the Flentje absorber, made in Cambridge, Mass., uses glycerine, which is contained in a vertically placed cylinder, connected to the axle, while a piston moving inside the cylinder is fastened to the body or frame. This form has been on the market for several years, but for the season of 1910 has been changed somewhat. A spring has been added on top of the packing of the stuffing box, and a hollow piston rod with a regulating valve. Fig. 1 shows a section through the improved device as well as an exterior view, which gives a good idea of its appearance.

Kilgore Manufacturing Company—In the second figure is shown a section through the product of the Kilgore Manufacturing Company, of Boston, which is also a fluid device. In this there are no valves, a by-pass being provided in the side of the cylinder, within which the piston reciprocates. The resistance which this by-pass and the walls of the cylinder offer to the passage of the air forms the cushion upon which the passengers actually ride.

Hartford Suspension Company—At the automobile shows this device is shown in practical operation on a couple of miniature cars. The friction between several circular plates, some of which turn with an arm attached to the frame, while others are attached to the other arm, which is fixed to the axle. The tension between the faces of the plates is adjustable, a nut to bind the

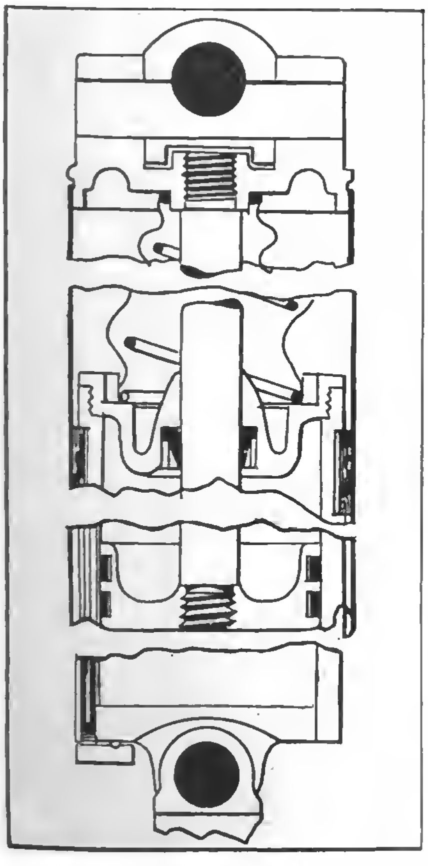


Fig. 2—Kilgore piston device

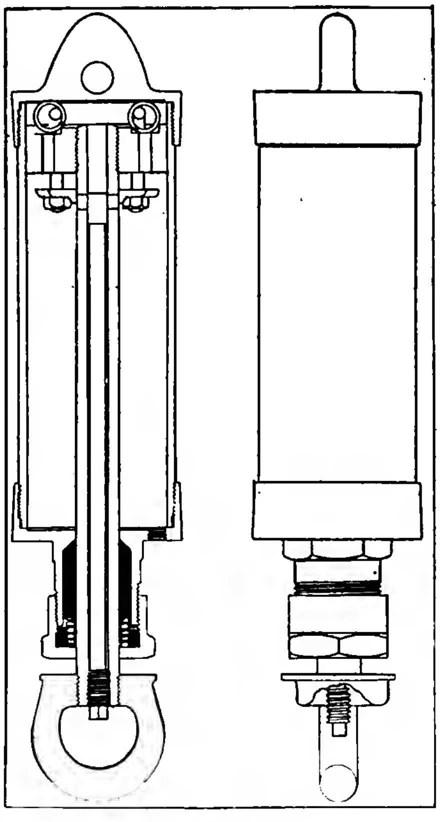

Fig. 1—Flentje glycerine cylinder

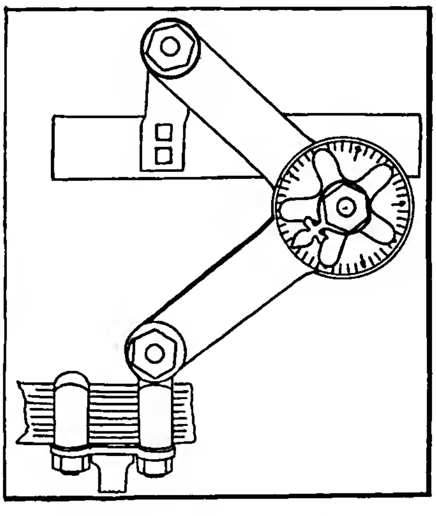

Fig. 3—Hartford Shock Absorber

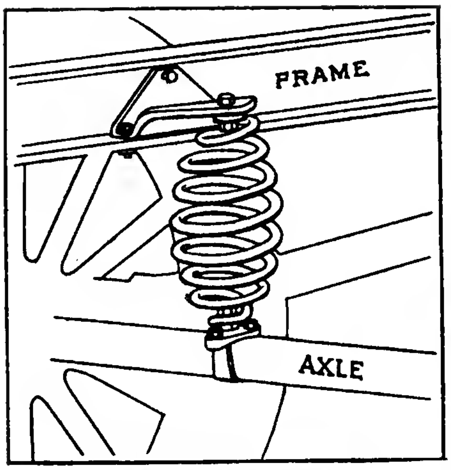

Fig. 7—Sager spiral spring absorber

surfaces against one another being provided for this purpose. It is made by the Hartford Suspension Company, Jersey City, N. J., and is shown in Fig. 3.

Westen Manufacturing Company—Like the Hartford, this is of the circular frictional plate type and is made in three sizes for three differing weights of cars by the Weston Manufacturing Company, Newark, N. J. Two friction planes are used, one being an integral part of the arm fixed to the frame, while the other is made up of an extension of the other or axle arm. The contact between the two is adjustable.

Gabriel Horn Manufacturing Company—Fig. 4 shows the Foster shock absorber, made by the Gabriel Horn Manufacturing Company, Cleveland. This is new and works upon a new principle. An elliptical cup is fastened to the side member of the frame, which is encircled by a friction band, lined with a specially prepared friction lining. The latter has two arms which attach to the axle, or rather to a lever which attaches to the axle.

Shippey Company—Like the preceding, the Shippey absorber, made by the George E. Shippey Company, Pittsfield, Mass., is of the frictional form. Sliding friction enters here, however, the free end of the device sliding up and down between the other two fixed ends, which are tightly held together.

Acme Spring Check Company—Practically all of the details of the Shoc-sorber, made by the Acme Spring Check Company, Broadway, New York City, are shown in Fig. 5. In this the working principle differs from the preceding, as a sectional filling of second growth hickory works against a ring, which is provided with steel rollers.

F. R. V. Sales Company—Springs form the basis of a goodly number of shock absorbers. Of these, the F. R. V., made by the company of that name, located on Broadway, New York City, uses a spring shock which is connected to the axle through the medium of a chain. The latter winds up or unwinds according as the load is decreased or increased. Fig. 6 show this form.

Bicalky Auxiliary Spring Company—This Buffalo firm makers a road-smoothing device which bears the firm's name. In this the spring assumes a spiral form, beirg wound up by the rise of the car body.

Sager Company—Fig. 7 shows the product of the J. H. Sager Company, Rochester, N. Y. This is a simple coil spring

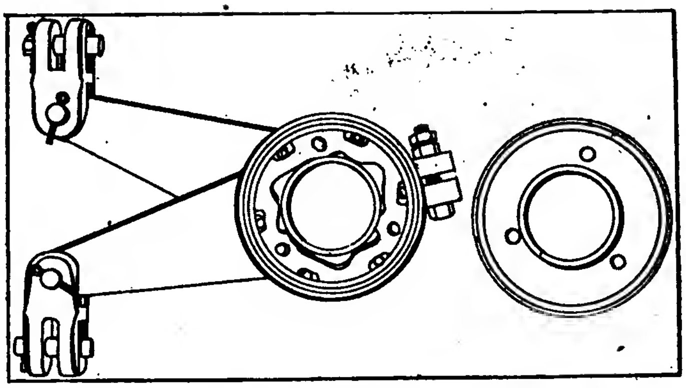

Fig. 5—Shocsorber utilizes hickory for a friction surface

interposed between the frame and axle in such a way as to be in tension during the rise of the body and in compression during the fall. This makes for long life, which quality is increased by the shape given to the springs themselves.

Baldwin Chain Company—This device is much like one of those previously described—that is to say, it consists of a coil spring attached to the two separating parts, the axle and frame, through the medium of a direct attachment in one case, and a chain which is paid out or taken in in the other.

Supplementary Spiral Spring Company—As the name would seem to indicate and as the Fig. 8 shows, this consists of a pair of small spiral springs interposed between the scroll end of the usual side spring and the frame or shackle, as the case may be. This is made by the Supplementary Spiral Spring Company, St. Louis, and has been very successful in its use.

Buffalo Specialty Company—The Thomas shock absorber is made by this Buffalo, N. Y., firm. These consist of a spiral spring, which is attached to the frame directly and above the axle. The connection to the latter is by means of a strap. The latter gives somewhat, while the spring yields considerably.

H. & F. Mesinger Company—Just like the Thomas, the Mesinger spring rebound check, made by H. & F. Mesinger Manufacturing Company, New York City, is composed of a combination of coil springs and leather straps. In this case, however, the construction is very simple, two coil springs being attached to each side of the frame in front of and behind the axle in the manner as shown.

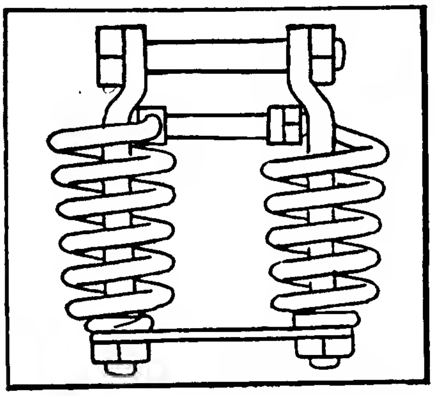

Fig. 8—Supplementary spiral spring

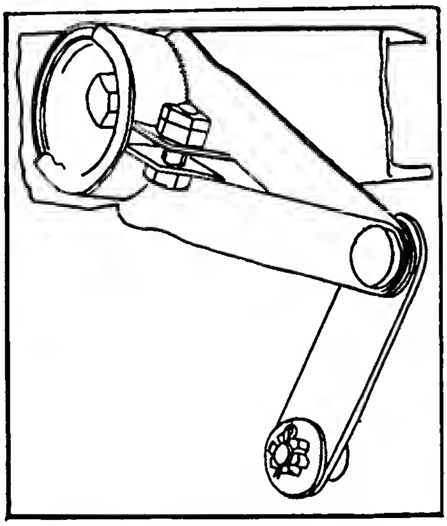

Fig. 4—Foster's shock absorber

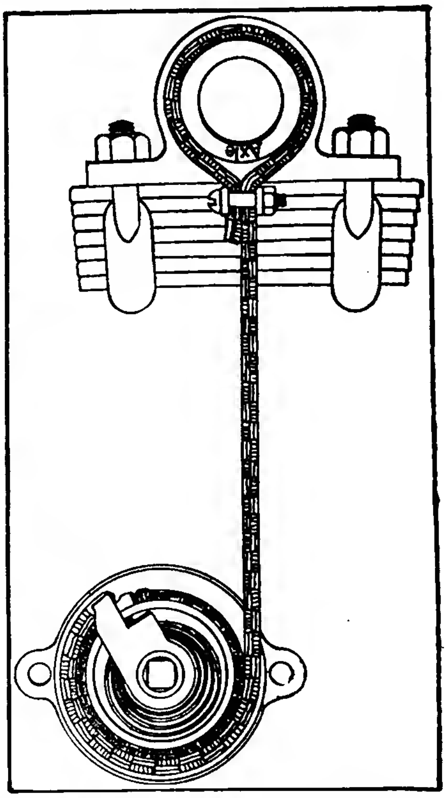

Fig. 6—F. R. V. uses spring and chain

SIGNALLING METHODS DEFINITELY CARED FOR

SAFETY is the keynote of all signalling devices, whether it be the selfish motive of personal safety or the more impersonal one of decreasing the dangers for the other fellow, the luckless one, who perforce must walk. Over and beyond the question of safety, although considered later on, is the matter of convenience.

This is made apparent by considering the case of a country road with a team occupying the center of the good going, and the driver of the same wholly unconscious of the automobile behind. Again, in city streets, when in a hurry one is often blocked off by a heavy, slow moving horse truck. In either of these cases, as well as in numberless others which might be mentioned, a polite request to move aside, as expressed by a proper signal on the horn, will usually give the much-desired result immediately.

More than this, the matter of passing another rig is attended with considerable danger to both parties, unless both are aware of and recognize the fact, making due allowance for the same. This sounds like a small item, but the danger is not only to the occupants of the two vehicles, but there is much danger of the vehicles being smashed up. The latter spells big expense for the motorist and comparatively large monetary outlay for the horse-drawn vehicle owner, as well as the inconvenience and delay in the latter case. Thus a farmer cannot borrow teams as he wishes during the busy season on the farm, and, in a case of this sort, the crops might rot or at least spoil, so as to be useless, while the farmer was endeavoring to secure another vehicle. So, the motorist should be thoughtful of others, and not only possess a good signaling device, but use it very freely as well.

In this connection, the automobilist would do well to bear in mind that when he has sounded a signal he in part frees himself from legal responsibilities, while in the absence of the same, the law will very likely be construed against him, to his financial detriment, and otherwise to his inconvenience.

There was a time when the hand-operated signal was universal, but with progress in other parts of the automobile has come also many improved methods of signalling, a number of them providing a signal which is not only produced easier and with less physical effort, but is of far superior value as a signal on account of its far-reaching qualities.

The public as a whole has taken kindly to the latter, and to such an extent that it might be said without disparaging the manually operated horn that the other types are increasing in numbers to such an extent as to become the majority instead of the minority, as before.

Generally speaking, the whole field of signalling devices may be divided into three large, principal classes, under one of which heads all may be classified. These are the electrically operated signal, the exhaust or air operated device.

Within one of these three classes, nearly every known automobile signaling system may be classed, for there are very few, if any, cases in which the device comes under a different head, while the devices which come under two of these heads are also like hen's teeth, few and far between. It is hardly possible to say how many horns are in use of any one of the three classes, although at one time the manually operated signal was in the lead, and probably had close to a monopoly. The other two forms, the exhaust, or air operated, and the electrical signal have both cut into the field of the hand horn to such an extent, however, that it is impossible to say with truth that the latter is now mostly used. Between the two newest forms, it is also difficult to say which is the more popular, despite the differing prices of the two. Thus, the lower priced of the two is the exhaust horn, while the other appeals to the class of buyers which has little consideration for the expense. Electricity in all of its branches is a mystery to many people and instead of investigating and learning the truth of its simplicity, they avoid it, the result being that the unwarranted prejudice against things electrical has held back and unjustly, too, the electrically operated horn.

Lovell-McConnell Manufacturing Company—Probably the derivation of the name of this horn, the Klaxon, will explain clearly the sound which it produces. The word Klaxon was made up from the Greek word "Klaxo," meaning to cause a roar or shriek, and that is exactly the result obtained. This is done by the very rapid vibration of a specially prepared steel disc. The extra rapid vibration is brought about by the impingement of a ten-toothed wheel against a button-shaped shoulder in the center of the disc, the wheel being rotated by a small and very compact electric motor. The latter is driven by either dry cells or a storage battery, and its speed is increased so that the three thousand revolutions per minute of the motor become thirty thousand per minute vibrations at the disc. Being operated by the simple act of pressing a conveniently located button, its use is a great convenience, as

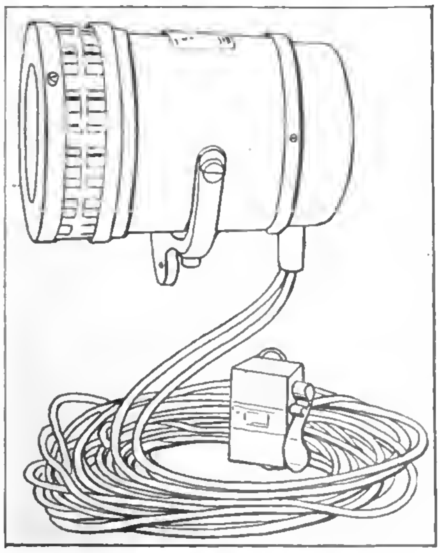

Fig. 2—Klaxon hand-operated siren

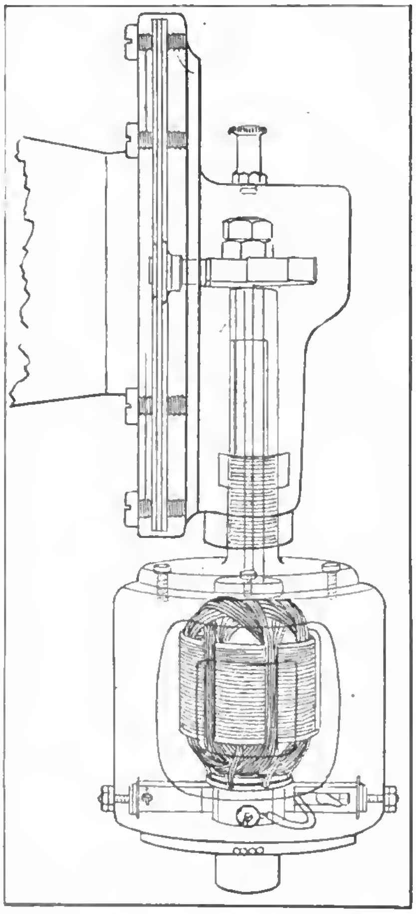

Fig. 1—Klaxon electrical horn complete

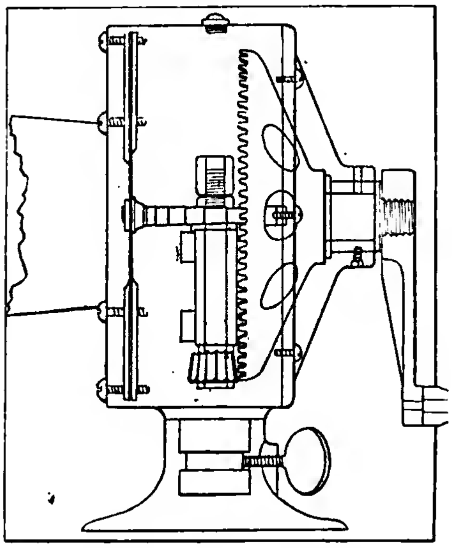

Fig. 3—Sireno turbine horn and switch

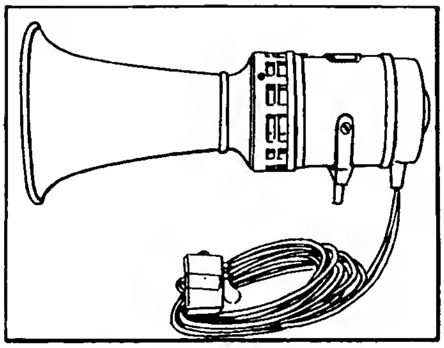

Fig. 4—Sireno Junior horn

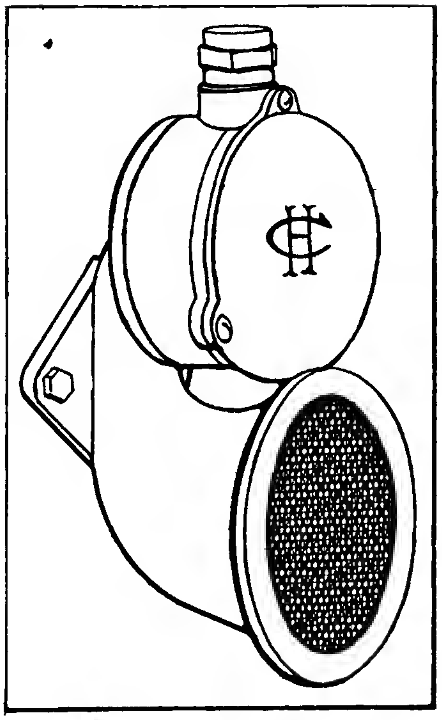

Fig. 5—Holtzer-Cabot electric horn

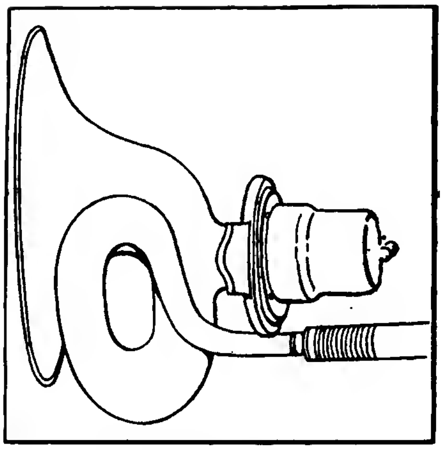

Fig. 6—Jones electric horn

this may be done without diverting attention from the road ahead. Safety is thus doubly assured and the idea good.

Sireno Company—This, too, comes in the first class, the electrically operated one, as it is a producer of sound through the medium of a cast-aluminum turbine, which is clamped to the shaft of a small electric motor. The turbine itself revolves, and this revolution causes the noise. To reduce wear and friction to a minimum, the armature is mounted upon a pair of ball bearings. A magnetic brake is added to stop the rotation, and with it the sound. These horns are made in several sizes, two of them being shown in Figs. 3 and 4. The former shows the large turbine horn, while the latter is a smaller size known as the Junior.

Holtzer-Cabot Electric Company—This Boston firm shows a direct-current electric horn differing from the others. As Fig. 5 indicates, it has a very neat, distinctive appearance, being compact, waterproof, and, what is more desirable than either, reliable. It may be wound specially for the work to be done on any pressure up to 123 volts, which may be sustained for five hours without injury. A superior interior construction has eliminated sparking at the contacts, even at high voltages. Its adoption by the United States Navy for emergency signalling speaks as highly of it as is possible to do.

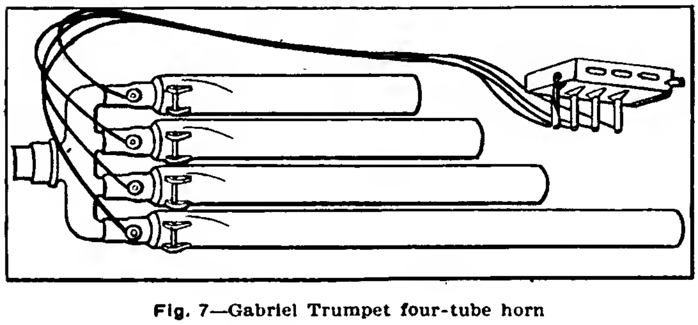

Fig. 7—Gabriel Trumpet four-tube horn

Electric Auto Horn Company—Since many owners adopted the hand-operated horn some time ago, and still possess good usable horns, which they would not care to throw away, this attachment will fill in very nicely, permitting as it does an electric attachment for old-style horns. This attachment operates by means of a push button, a set of dry cells or a storage battery being the source of current. The rotating member is wired up so as to set just back of the reed of the horn, so that the finished device has some of the advantages of both, the convenience and ease of application of the electric horn and the economy of using the old horn, as well as the softer sound produced by the reed. In addition, the whole outfit is not expensive.

United Manufacturers, Inc.—In the Jones electric horn shown at both shows by this firm, the sound is produced by the rapid vibrations of the diaphragm, which is set into motion by electro-magnetic means. As with each of the other electric horns, the current from dry cells or storage batteries is equally applicable. Many types are made, varying from the one shown in Fig. 6 in size, style and weight. The usual form has a 12-inch bell, a close-coupled body, and is operated by a push-button placed on the steering wheel.

Gabriel Horn Manufacturing Company—Better than ever describes the 1910 Gabriel horns. These are made in the same styles as before, with the addition of a number of new types. Among the latter may be specially mentioned as accorded first place at the show is the new Gabriel trumpet, illustrated in Fig. 7. This consists of four single tubes, with a small valve at the end of each tube, each valve controlling its own tube. The four keys shown operate the four tubes. This allows of the use of any single note, or by the combination of the four, any combination of trumpet and bugle calls is possible. In addition, the keyboard is fitted with a small lever which operates all four valves at once, thus producing a single note for signalling purposes. As is well known, these horns are operated by the exhaust pressure, or if the car be equipped with an air compressor this may be utilized, the action being the same, whatever the source of fluid pressure. This pressure is applied for signaling purposes through the medium of the keyboard.

Randall-Faichney Company—In the Jericho horn shown at both shows, and pictured in Fig. 8, this company, hailing from Boston, has an exhaust horn which is very effective. It is operated by foot pedal, depressing which closes the horn lid, forming a slot through which the exhaust gases are directed across the sound chamber opening. As the slot exists only when the lid is closed, it is impossible to choke or clog it. Immediately upon the release of the foot pedal, the exhaust has the usual full opening toward the ground, the sound chamber being so placed as to open downward. In position on the car it is placed behind the muffler, so has no effect upon the muffling or power of the motor

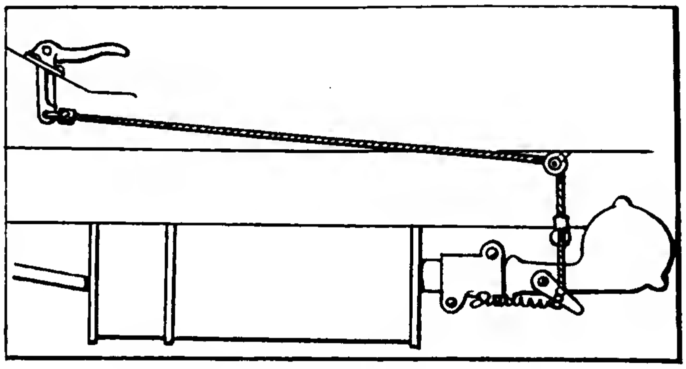

Fig. 8—Jericho horn and scheme of operation

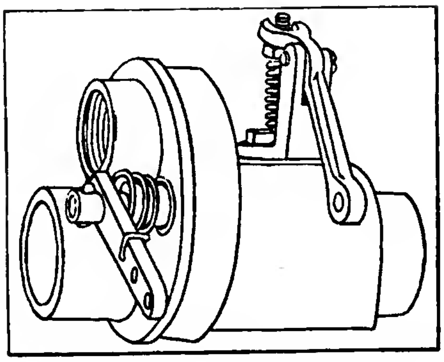

Fig. 9—Gray-Hawley Autochime Valve

with which it is used.

Nightingale Whistle Manufacturing Company—This, too, is an exhaust operated horn, being of French extraction, which the importers have, however, improved upon greatly without changing the fundamental principle. In the changing process the idea has been to make it and its attachment to a car as simple as possible, so that any mechanic, or even a private owner, could attach it without trouble. In this they have succeeded admirably. It is held on by means of clamps, which are designed to fit any exhaust pipe. In addition, the company is showing a new motorcycle signal along somewhat similar lines of construction.

Not the least attractive article the Nightingale Whistle Manufacturing Company is handling is the air compressor outfit for garage purposes. This consists of the very efficient little water-jacketed air pump, known as the Delpeuch air compressor, of metal throughout, with no leather packing or washers, which this company has been marketing for the past two years, the new feature being that they are furnishing a complete outfit for filling tires, including a guaranteed air-tight tank, safety valve, globe valves, and all necessary fittings, at the usually responsible prices consistent with the known policy of the company. The material and workmanship employed in the production of these outfits are of the highest grade obtainable, and no effort or expense has been saved to secure the greatest degree of efficiency; every part of the outfit is guaranteed. The compressor is already well and favorably known to garages throughout the Eastern states, and is being used not only for filling tires but cleaning engines, upholstery, etc.; it is the greatest labor-saving device garages can secure.

Gray-Hawley Mfg. Co.—Known to the trade as the Autochime, this exhaust horn has a number of individual features of sterling worth. This consists of a cylindrical body portion, containing the sound openings, and a valve for operating, which possesses a number of features of its own. Among these may be mentioned simplicity, durability, self-cleaning properties, accessibility, etc. It gives excellent control over the horn, which may be blown at any time, regardless of the speed of the engine. It is made in sizes to fit all exhaust pipes from 1 in. up to 2 in. The body of the Autochime proper is made of the best grade of selected brass, and is about 2 in. in diameter by 15 in. long.

Tsar Auto Horn—Another exhaust horn which possesses

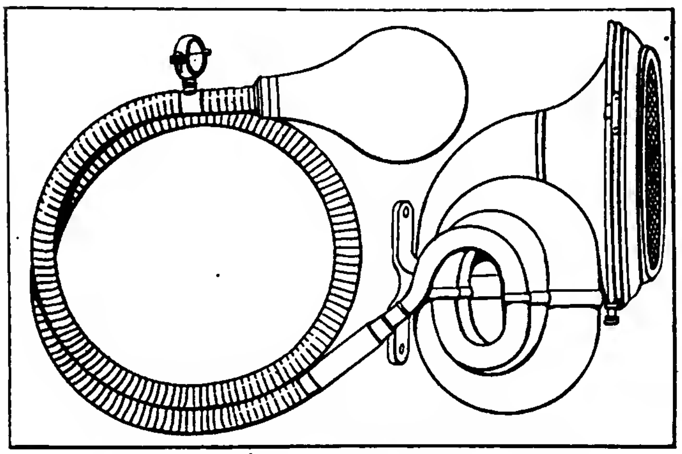

Fig. 12—Riley-Klotz Triple Twist horn complete

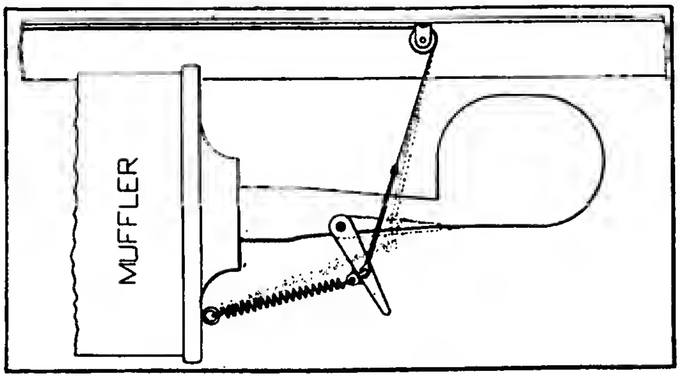

Fig. 10—Tsar exhaust-operated horn

the unusual feature of being quickly and easily attached to any car. This is attached to the exhaust end of the muffler, and requires no cut-out, although it may be used in connection with one, just as well as in cases where the cut-out is dispensed with. The makers state that it may be attached by any ordinary mechanic in less than two hours, with very few and simple tools. When in place it requires no attention, not even cleaning, as it does that little act itself. Being essentially simple, there is nothing to dislodge or get out of order. Fig. 10 gives an idea of the appearance, as well as showing the method of operation.

Charles E. Miller—This dealer is showing, among other things, the Testophone horn, Fig. 11. It has four tubes of varying lengths, which are worked by means of a single bulb. This result is something out of the ordinary, being produced through a special apparatus by successive compressions of the one bulb. The sound is a series of notes, which somewhat resembles a bugle call. Or, by the continued use of any one, a single prolonged trembbling note of gradually increasing force may be produced. On the other hand, a single note is obtained by turning the cylinder when the piston is at the end of its travel. The whole horn is prevented from working by means of this same cylinder, which is turned when the piston is at rest.

Automobile Supply Mfg. Co.—In the Nonpareil hand-operated brass horn this Brooklyn supply house has an excellent exhibit. The finish and workmanship follow along French lines, the foreigners having been the best horn makers for some time.

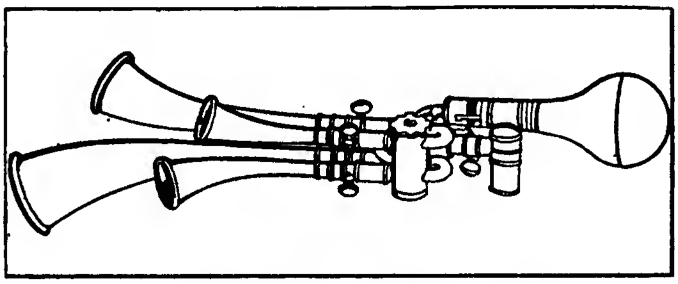

Fig. 11—Testophone horn has four tubes

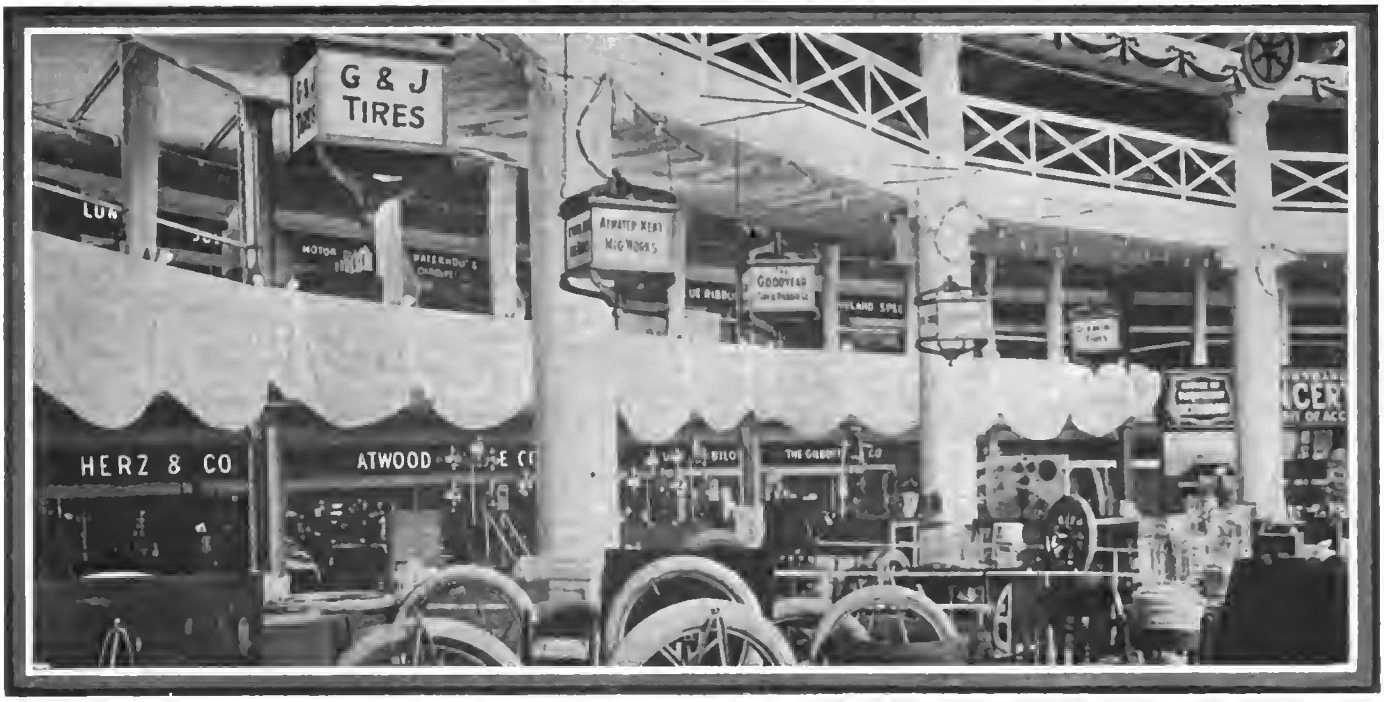
A bulb of chemically cured rubber of large size secures instant and continuous operation, while the tone produced is best described as long-drawn-out, deep and penetrating.

Post & Lester Company—1910 models of the Volier horns are exhibited by this supply concern from Hartford, Conn. They are in two main styles, medium diameter oval and large diameter oval, both being of the hand-operated type. The bulb is of chemically cured rubber, the material of the horn heavy sheet brass, while the reed is of non-corrosive vibratory metal, which will give a maximum of service with a minimum of trouble.

Riley-Klotz Mfg. Co.—The triple twist horn, known by the prosaic name of No. 27, is shown in several styles. This is a manually operated horn with an oval bell, screen across the mouth of the bell, and fitted with a 50-inch tube, which is long enough for any purpose. The finish, material and workmanship are excellent throughout.



A Corner of the South Gallery Where the Display of Accessory Makers Was Imposing and Characteristic

NOTABLES GATHERED IN EXTRA FORCE

GLANCING over the list of names of the princes of the automobile fraternity who attended the gathering at the Garden proves to be of more than a little interest, partly due to the assembling in unusual force, then in view of the quality of the representation. In many cases, besides the heads of companies, there were numbered among the attendance the whole administrative force, which was augmented somewhat by a goodly scattering of executive "staff" men.

The accessory division added to the tide of official attendance, and this year the accessory field is not only strongly presented, but it has assumed such important proportions that none seems able to tell what will be the end. To be sure, the many additions to the "Selden flock" had to do with the attendance, and, perhaps, the gathering was forced by those who wanted to ascertain what the future portrays.

F. E. Powers, president and general manager of the Gilbert Mfg. Co., of New Haven, Conn., also E. B. Spaulding, treasurer, and W. A. Rutz, sales manager of the same company, are all stopping at the Woodstock Hotel.

The Astor Hotel is the home of Frank Coes, president and general manager of the Coes Wrench Co., of Worcester, Mass., also of Edward Searle and Harry Streme, salesmen.

The Randall-Faichney Company, of Boston, Mass., is represented by W. A. Randall, president; H. L. Hillman, sales manager; E. P. Wallan, the New York representative, and E. R. Brackett and S. A. Campbell, who are all stopping at the Waldorf-Astoria.

Among those registered at the Hotel Manhattan are Brice S. Evans, the Boston sales manager of the Kilgore Mfg. Co., also J. L. Allen, W. Nielson and H. C. Michelsen, the New York representative of the same company.

Hopewell Bros., of Newton, Mass., is represented by Frank B. Hopewell, C. A. Russell and Charles F. Hillers. These gentlemen are staying at the Waldorf-Astoria.

Among the representatives of L. C. Chase & Co., of Boston, Mass., are William Walden and R. L. Gilman, who are registered at the Prince George Hotel.

Irving H. Atwood, general manager of the Atwood-Castle Company, and Fred L. Castle, vice-president of the same concern, are staying at the Hotel Astor.

The New Departure Manufacturing Company, of Bristol, Conn., is represented by A. F. Rockwell, president and general manager; De Witt Page, secretary and sales manager; C. J. Tredwell, treasurer; M. J. Horton, D. W. Graham, W. R. MacGuyer, and J. N. Biddle, who are all staying at the Hotel Belmont.

Ernest Flentje, of the Flentje Shock Absorbers Company, of Cambridge, Mass., also E. Y. Stimpson, N. Y. representative; Charles E. Miller, draftsman; J. A. Sawyer, general manager; N. H. Wishart, Pittsburg representative; H. Hess and B. Parry, all of the same company, are stopping at the Hotel Empire.

The Hoffecker Company, of Boston, Mass., is represented by F. D. Bennett, general manager and E. M. Rollins, sales manager, both of whom are registered at the Belmont.

The Post & Lester Co., of Hartford, is represented by H. W. Lester, treasurer and general manager; C. B Lamb, secretary; G. R. Hall, Western representative; E. L. Thompson, manager of the Boston branch; T. A. Cotter, manager of the New Haven branch, and T. M. Tarbell, manager of the Springfield branch.

Among those representing the Heinze Electric Company, of Lowell, Mass., are J. O. Heinze, general manager; P. J. Legare, sales manager, and Lionel Loupret and J. A. Malone, advertising managers, who are al. stopping at the Hotel Belmont.

The Pittsfield Spark Coil Company, of Dalton, Mass., is represented by W. P. Wood, general manager; Thomas Wetzel, sales manager; K. Franklin Peterson, H. V. Greenwood, L. D. Bolton and W. J. Connell. These gentlemen are all stopping at the New Amsterdam Hotel.

Among those representing the Dover Stamping & Mfg. Co., of Cambridge, Mass., are H. E. Whitney, president, and H. M. W. Brigham. These gentlemen are stopping at the Hotel Woodstock.

During show week the Waldorf-Astoria is the home of William Gray, general manager of the firm of Gray & Davis, Amesbury, Mass.; also of Lambert Hollender, Alex Churchward, C. H. Munson, D. H. Elkins, Ed. Taylor and W. H. Gray, of the same company.

Witherbee Igniter Company, of Springfield, Mass., is represented by Phelps Brown, vice-president and treasurer; Theo. Getz, salesman; C. D. Galloway, salesman, and Mark W. Heath, Chicago branch manager.

The Allen Tire Case Company, of New York, is represented at the shows by William A. Allen.

Martin V. Kelley, of the MacManus-Kelley Company, of Toledo, is attending the show in the interests of his several clients. He is also making a trip to the Hartford Rubber Works, whose business he handles.

A. A. Atwood, Overland distributor in northwestern Ohio, registered in Monday.

Whitlock Coil Pipe Company, of Hartford, Conn., is represented by James L. Goodwin, general manager and treasurer; Richard Thompson and W. E. Kinney.

Couch & Seeley Company, of Boston, Mass., is represented by R. L. Whitman, treasurer; F. J. Bordeaux, sales manager, and L. A. Casgrain. These gentlemen are staying at the Belmont Hotel.

William Johnson, the well-known Denver dealer, is registered at the Cumberland.

Edgar Apperson, of the Apperson Bros. Automobile Company, and George Strout, sales manager of that company, are stopping at the Cadillac.

Among those registered at the Woodstock are N. H. Van Sicklen, president of the Automobile Blue Book Publishing Company; David Beecroft and N. H. Van Sicklen, Jr., of "Motor Age," Chicago.

J. McGill, of the Consolidated Supply Company, of Denver, is registered at the Cumberland. John E. Fry, of the same company, is also in town.

Fred C. Rohle, of the Excelsior Supply Company, of Chicago, and Chester C. Boynton, of the same concern, are at the Astor.

Carl Metzger, of the Woods Electric Vehicle Company, of Chicago, is registered at the Astor.

The Keystone Lubricating Company, of Philadelphia, is represented at the show by A. C. Buzby, president; H. A. Buzby, secretary and sales manager; C. A. Hopper, T. W. Armstrong, H. L. Carpenter, W F. Beitler and E. C. Huhn. These gentlemen are all stopping at the Hotel Breslin.

The Knickerbocker has among its guests this week F. A. B. Smith, vice-president of C. P. Kimball & Company, Chicago, and Stuart B. Andrews, of the same company.

Charles E. Firestone, secretary of the Columbus Buggy Company, of Columbus, Ohio, is at the Collingswood.

General Manager Otis R. Cook, Federal Rubber Company, Milwaukee, is registered at the Belmont.

G. S. Chapin, of the Motor Car Supply Company, Chicago, is at the Astor.

Bertram Smith, manager of the battery department of the United States Light & Heating Company, of Chicago, is at the Seville.

The Empire Hotel has among its guests C. E. Breisford, of Detroit.

The New Grand Hotel is the home during the shows of B. F. Meixell, president of the Indiana Motor Sales Company, of Indianapolis, and A. C. Downing, general manager of the Meixell-Downing Company, of Indianapolis.

C. J. Smith and A. R. Burr, of C. J. Smith & Co., of St. Paul, Minnesota, are registered at the Breslin.

Among the members of the trade who are stopping at the Astor are L. P. Zinke, J. W. Fulton, P. L. Hussey and Fred McManus, of the F. Z. H. Parts Co., of Chicago.

John J. McCutcheon, "the big fellow," Western manager for C. F. Splitdorf, is registered at the Astor, as is also Harry E. Fields, of the Hartford Rubber Works.

William Schebler, of Wheeler and Schebler, of Indianapolis, is registered at the Waldorf-Astoria.

J. B. Long, president of the Long Mfg. Co., of Chicago, is registered at the Waldorf-Astoria.

J. A. Boyle, general manager of the Briscoe Mfg. Co., of Detroit, is stopping at the Belmont.

S. F. Briggs and H. M. Stratton, of the Briggs & Stratton Company, Milwaukee, were among the visitors at the show on Monday.

Fred S. Duesenberg, the superintendent of the Maytog-Mason Motor Car Company, of Waterloo, Iowa, is in town for both shows.

W. L. Easterly, Indianapolis representative of the Firestone Tire & Rubber Company, is at the Murray Hill Hotel.

K. Franklin Peterson, of Chicago, and L. D. Bolton, of Detroit, are at the Belmont.

P. S. Steenstrup, general sales manager of the Hyatt Roller & Bearing Company, is stopping at the Belmont.

Among those registered at the Latham Hotel is H. W. Gray, manager of the Neustadt Auto & Supply Company, of St. Louis.

The Cumberland Hotel has among its guests C. E. Lipman, president of the Lipman Mfg. Co., of Beloit, Wis., and George Wahlgreen, of Denver, Col.

Among those registered at the Manhattan Hotel are F. E. Eckhart and J. I. Farley, of the Auburn Automobile Company, of Auburn, Ind.

President C. B. Hayes, of the Hayes Wheel Company, of Jackson, Mich., is registered at the Webster Hotel.

H. B. Krenning, president, and G. P. Dorris, vice-president Dorris Motor Car Company, St. Louis, who are here for both shows, are registered at the Knickerbocker.

Seamless Rubber Company, of New Haven, Conn., is represented at the show by W. Williams.

Whitney Manufacturing Company, of Hartford, Conn., is represented by Clarence Whitney, general manager.

Among those who are in attendance at the show in the interest of the White & Bagley Company, of Worcester, Mass., are H. P. Bagley, general manager; A. F. Kelley and A. G. Guy, who are stopping at the Imperial Hotel.

The A. W. Harris Oil Company, of Providence, R. I., is represented by A. W. Harris, president and general manager; B. S. Terry, W. T. Kincaid, George F. Haywood, Howard L. Gaunt, E. V. Harris and W. L. Larash.

C. T. McCue and L. D. Parker are representing the McCue Company, of Hartford, Conn.

The Novelty Mfg. Co., of Waterbury, Conn., is represented by Oscar Fitzsimmons, secretary; F. L. Cowles and E. W. Kingsley.

L. J. Mutty Company, of Boston, Mass., is represented by L. J. Mutty, W. J. Hoynes, Edward Patrick Murray, Henry B. Harris, Peter Welin and J. Eugene Rogers, who are staying at the Holland.

Fred A. Ballou, Buffalo representative for the Palmer & Singer and Selden cars, is registered at the Hotel Imperial.

C. Cowles & Co., New Haven, Conn., is represented at the show by L. C. Cowles, president; F. M. Ruwet, M. S. Bottume, Harry Bradley, stopping at Prince George Hotel.

The Springfield Metal Body Company, Springfield, Mass., is represented by Hinsdale Smith, president; A. P. Smith, treasurer; W. T. Helfer, sales manager; J. B. Richards, superintendent, and H. L. Rich, who are stopping at Hermitage Hotel.

Baldwin Chain & Mfg. Co., Worcester, Mass., is represented by W. H. Gstes, treasurer and general manager; M. V. Greenwood and M. A. Bryte, stopping at Belmont Hotel.

Another Section of the Accessories Exhibits

L. D. Parker is attending the shows in the interests of Parker Motor Company, Hartford, Conn.

A. L. Dixon, general manager Brunner Motor Car Company, Buffalo, is at the Breslin.

E. W. McGookin, Detroit, is at the Astor.

Roger B. McMullen, Chicago, is at the Latham.

Ezra E. Kirk, Western sales manager Rainier Motor Company, of New York, is at the Manhattan.

F. H. Wheeler, of Wheeler & Schebler, Indianapolis, visited the Palace and Garden shows and left for Bermuda, Wednesday, by the "Bermudian," for a few weeks' stay.

W. S. McDonald, manager Detroit branch The Buda Company, of Chicago, is at the Astor.

James A. Hollhan, sales manager Briscoe Mfg. Company, Detroit, is at the Belmont.

F. B. Sears joined his colleagues of the Auburn Automobile Company Tuesday, and is registered at the Manhattan.

Morris Eckhart, general manager, is ill at home and was unable to come East for the shows.

General Manager J. P. Elmer, sales manager Richard Bacon, Jr., Frank Nutt, engineer, and S. H. How, sales department Haynes Automobile Company, Kokomo, Ind., are registered at the Woodward. C. C. Craig, manager Chicago branch, is at the Woodstock.

E. H. Webb, Detroit representative of the Royal Equipment Company, is at the Manhattan.

D. B. Smith, of The Standard Company, Torrington, Conn., is at the Breslin.

TORPEDO TYPES OF BODIES OPPORTUNE

Granting that body work has long ago departed from carriage makers' practices, even so, murmurings, from time to time, which seemed to be out of tune, rather lead to the conclusion that something was wrong, or, better yet, that body work fell short of the requirement; a condition, to be sure, which could not have been foreseen. Experience has ever been the great teacher, and as this same influence ripened the judgment of autoists, it bestowed upon them the right to think—to think for themselves. That autoists do think is proven by the extent to which they are considered by the most advanced designers, and it is due to a desire to anticipate the needs of users of automobiles that so many changes were made all along the mechanical line, and body work is now coming in for its share of attention.

The presence of several determined examples of torpedo bodies, with differences in detail only, as between them, is but a reflection of the wants of purchasers; they preferring a fair measure of comfort, and, as experiences seems to have pointed out, a body which suffices for a carriage involving a speed of less than 20 miles per hour may be open at the sides without serious handicap.

For several years it has been the practice to protect occupants of the tonneau in every possible way, and a side door was found to be the most practical way of doing so. Why the driver, who has the lives of the occupants and the public in his keeping, should be left out in the cold, is a detail which will require a little explaining, but owners, who drive, invariably complain of side-draughts when they come out from behind the breast-works. Contrast is an efficient illustrator.

Torpedo types of bodies alter the whole situation to a material extent; comfort is equally divided between the front and rear seats, and the power required to propel the automobiles so fitted is reduced materially below that which comes with unsymmetrical conformations. Torpedo bodies are probably destined to be with us long.

PRESSED STEEL AND FINALITY ON TERMS

Castings, like the man "Friday" in the story of Robinson Crusoe, befit a primitive situation. They were the most ready-to-hand, in the early days when shops devoted to the turning out pressed steel work were but few, and they, for the most part, were confined to car work as it applies to railroads or in the manufacture of guns.

When automobiles first came into vogue, they were built in small numbers, and the designs were on so unstable a footing that changes were in rapid succession. Under the circumstances it was as a simple process to whittle out patterns in wood, deliver them to a foundry, and have castings run off. The growth of the industry added stability in designs, and the expansion of plants devoted to pressed steel work are responsible for a change all along the line.

It is useless to go on saying that production in quantity leads to better quality unless reasons can be given, but, fortunately, the reasons are on the surface. They are exposed to the searching glare of a tropical noonday sun, and in this light, when the last word is said, it is the presence of pressed steel, in the absence of castings, which is at the bottom of the whole situation—a state of glowing health.

TIRES FALL HEIR TO SANE TREATMENT

Improved methods of tiremaking, while they are positive, and include better materials for fabrics as well as first selections of rubber, do not account for the better service which is undoubtedly being rendered by tires. It is in the manner of adapting tires that accounts for more than a little of the increased satisfaction; larger diameters are in evidence; greater sections prevail, and, what is equally important, tire pumps, with accurate gauges, are used in the inflating operation.

It is now a settled fact that inflating, unless it is most carefully done, will be at the bottom of rapid deterioration; moreover, it is necessary to have all four tires pumped up equally. Flexure is what ruins tires, and this phenomenon is decreased materially as the sizes of tires used are larger, and if they are inflated to a satisfactory point—which is possible when the tires are large enough for the car.

Again, demountable rims are in force, nearly every large firm showing a form of demountable. This furthers the modern tendency to cater to the ease and comfort of the non-professional driver, who usually is not as skillful with tools as his salaried brother. This form is the acme of simplicity, so that any one can make the change, practically without tools at that.

ANNUAL MEETING MOTOR AND ACCESSORY MFRS. (INC.)

NEW YORK CITY, Jan. 5—Waldorf-Astoria, as a hostelry, was filled to overflow by the members and guests of the Motor and Accessory Manufacturers (Inc.), who were there to attend the annual meeting and be banqueted. Over 200 members were seated at the festive board, which was after the business of the meeting was over. In addition to current matters the business meeting ended in the re-election of the old officers and the board, which now stands as follows:

President, H. E. Raymond (B. F. Goodrich Company), Akron, Ohio; first vice-president, H. T. Dunn (Fisk Rubber Company), Chicopee Falls, Mass.; second vice-president, F. E. Castle (Atwood-Castle Company), Detroit, Mich.; third vice-president, C. E. Whitney (Whitney Manufacturing Company), Hartford, Conn.; treasurer, W. S. Gortin (Standard Welding Company), Cleveland, Ohio; secretary, P. S. Steenstrup (Hyatt Roller Bearing Company), Newark, N. J.

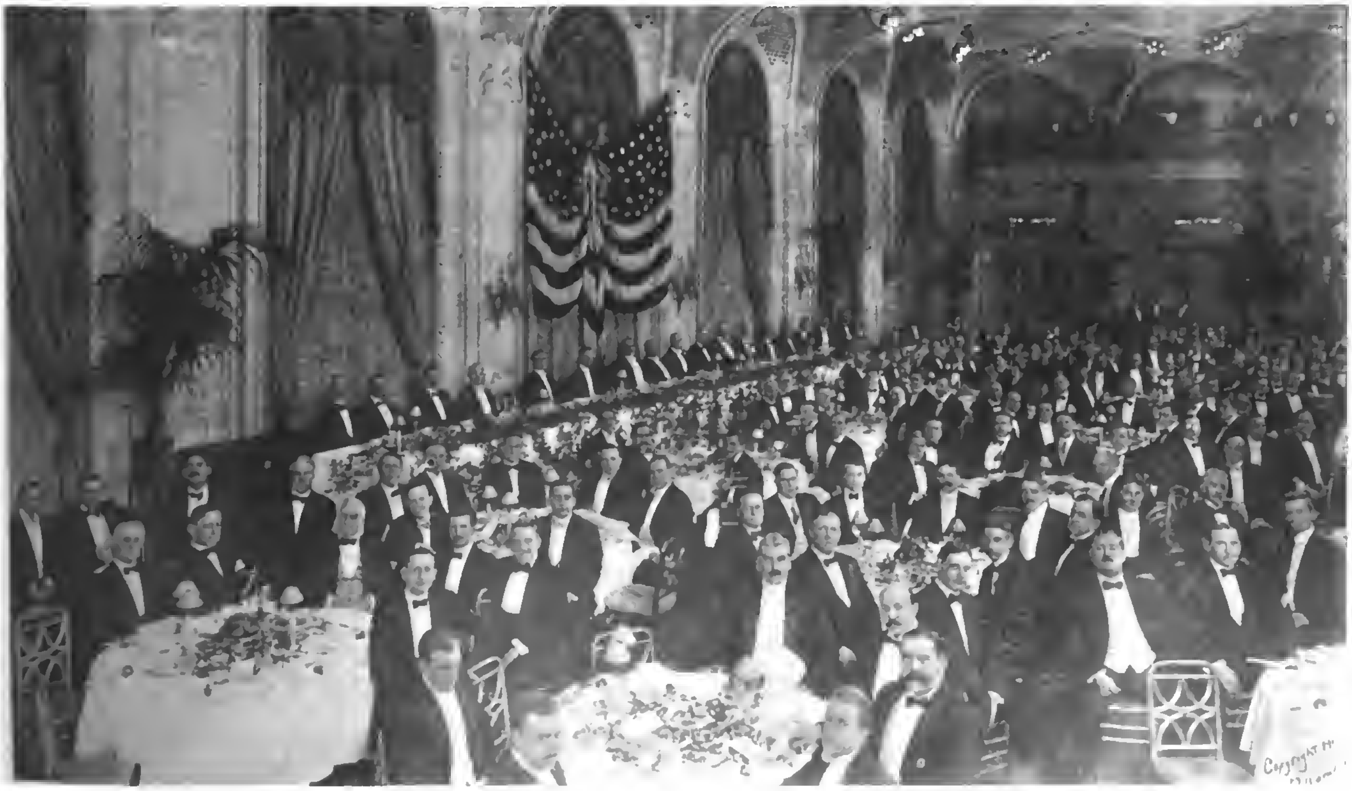
In addition to this regular list of officials a new office was created, namely that of manager of the association, which position was filled by the appointment of W. M. Sweet, who has been acting manager for the past year and has been associated with the organization since its inception several years ago. Mr. Sweet is a young man of hustling disposition and there is not the question of doubt but that the organization under his direct control will prove a most useful one for the industry during the coming season.

To-day the Motor and Accessory Manufacturers' Association is in a most promising condition, counting on its roster no less than 174 concerns, all of which are representative of the great accessory phase of the automobile industry. During the past year from thirty-five to forty new names have been added, one of which, the Auburn Auto Pump Company, Auburn, N. Y., was voted a member at the annual meeting. The present membership is, roughly speaking, 50 per cent. of the active accessory makers of the country, so that there yet remains big scope for the development of the organization. According to its present constitution the organization holds an annual meeting at this season of the year and a semi-annual one in the summer, in addition to which there are the quarterly meetings of the board of directors. The valuation of the industries at present in the association aggregates the big total of $307,000,000.

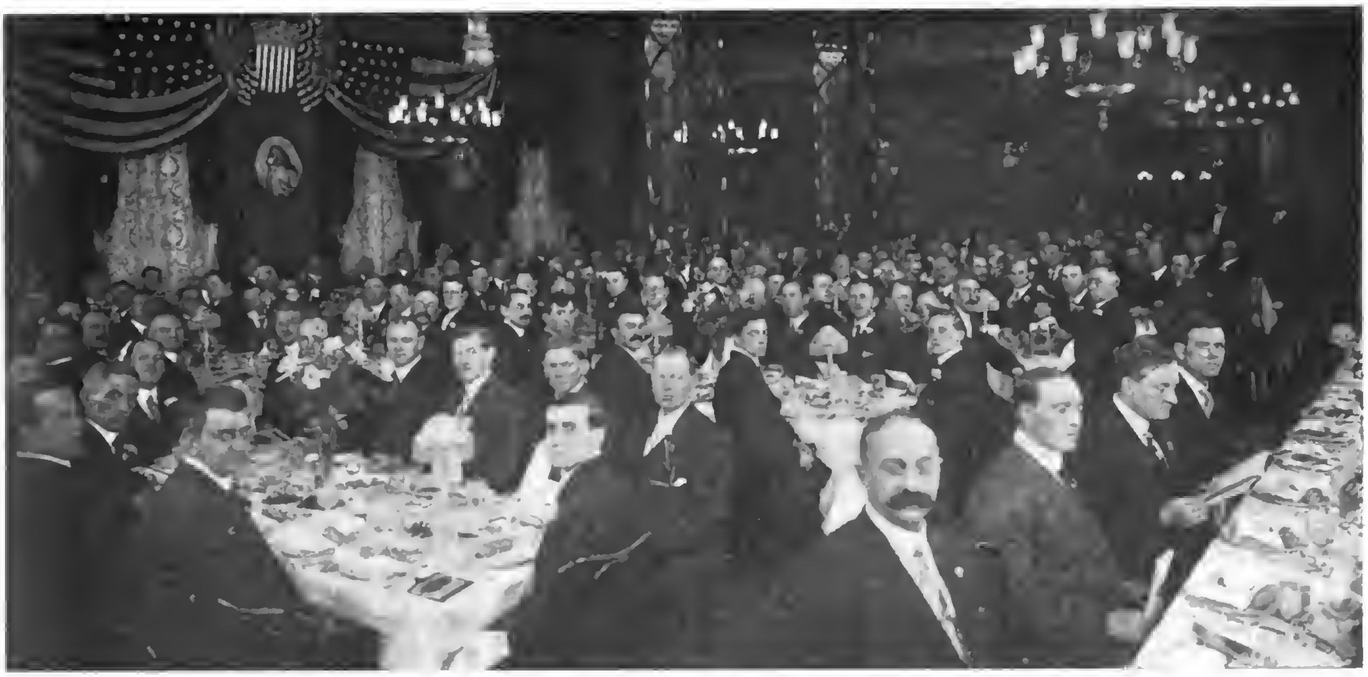
The annual banquet to a large extent took the place of the banquet which has been held every year up to the present by the American Motor Car Manufacturers Association, but which was dropped this season for the first time. The position of toastmaster developed upon Job E. Hedges, who has become familiar to the motoring fraternity by occupying similar positions during previous years, and throughout the evening his aphorisms were brimful of humor and common sense.

H. O. Smith, president of the A. M. C. M. A., the first speaker of the evening, dwelt on the present motor car situation and hoped that that same high order of business integrity would characterize every member of the accessory organization that has been conspicuous in the past. He looked for the time when gearsets or other important car parts would not be sold to concerns who would yoke them up in too powerful cars, and hoped the time was not far distant when a commission might be appointed whose duty it would be to pass upon such conditions.

Col. George Pope, chairman of the A. L. A. M. show committee, was reminiscent of old bicycle days and wished the present accessory organization every possible prosperity. Other addresses were made by John C. Wetmore, the dean of the trade press in motordom; Lewis Speare, president American Automobile Association, and Hon. Martin Saxe. The last speaker dwelt in particular on the engineering operations that are being carried on to-day in the vicinities of New York and which are working great good to the cause of the automobile. He referred in particular to the proposed bridge across the Hudson which will give New York motorists an outlet to the great State of New York on the west side of the Hudson. The participants left with a renewed feeling of good-fellowship and mutual interest.



Banquet of the Motor and Accessories Manufacturers, Inc., at the Waldorf-Astoria, New York City, January 5, 1910



Annual Banquet of Maxwell-Briscoe Motor Company, to Its Selling Forces, Hotel Manhattan, New York City, January 6, 1910

MAXWELL-BRISCOE ANNUAL BANQUET

Each year the annual banquet tendered by the Maxwell-Briscoe Motor Company to its agents and other representatives becomes a more enjoyable feature of that progressive corporation. These banquets given at the time of the Palace Shows when the attendance can be the largest, and that of the present year took place at the Hotel Manhattan, New York City, on Thursday evening, January 6, under the auspices of the sales organization of the company, and catered to 275 covers. The menu card was elaborate and was replete with caricatures of the leading lights of the Maxwell-Briscoe organization, the outside cover depicting a radiator upon which was embellished in color a large piece of beef roasting over a hot "rotisserie" fire.

E. R. Thomas Accepting New York-Paris Trophy

This year the usual quota of speechmaking was abolished, Mr. Briscoe making the speech of welcome, and introducing a program of vaudeville which was good and appealed strongly to the sentiment of the assembled guests. The head of the table was occupied by Messrs. Benjamin Briscoe and J. D. Maxwell, who were flanked on either side by the leading lights of the company's sales organization.

THOMAS GETS "ROUND THE WORLD" CUP

At a banquet at which nearly 300 guests partook of the hospitality of the E. R. Thomas Motor Company, the New York to Paris Trophy, offered by *Le Matin* of Paris and the *New York Times*, was formally presented by the representatives of the donors, at the Automobile Club of America on Saturday evening, January 7. There was a large table circling the banquet hall in the shape of a horseshoe, and at the oval's end was placed a table at which were seated the guests of honor and the officials of the Thomas company.

Robert Lee Morrell officiated as toastmaster and at his right and left were seated George Schuster and George Miller who were in the winning Thomas car almost constantly from the time it started on its 20,000-mile journey at Times Square, New York City, until it stopped in front of the office of *Le Matin* in Paris, 26 days ahead of its nearest competitor. Running all the way round the horseshoe-shaped table was a series of photographic views which depicted the progress of the journey.

At the toastmaster's signal Messrs. Schuster and Miller, accompanied by E. R. Thomas, advanced to the center of the horseshoe where the trophy stood draped with the American flag, and simultaneously pulling two wires they released the flag which fell disclosing to the assembled guests the symbol of their victory. The orchestra played "The Star-Spangled Banner" and the guests cheered. Mr. Thomas made a well chosen speech of acceptance on behalf of his company, and Messrs. Schuster and Miller told of some of their experiences in Siberia.

The trophy is said to be the largest of its kind ever made, and stands six feet six inches in height, weighing slightly over 1,600 pounds. The materials used in its construction are all native to the four nations represented in the race—the United States, France, Germany and Italy. The pedestal is of green Italian marble, and the sub-base is of French marble of beautiful pink shade. The medallions are of German bronze, depicting the coats of arms of the four competing nations, and the German bronze globe that surmounts the whole is covered in bas relief, showing the continents and the route of the great race in American silver. The whole is surmounted by a silver American eagle.

An elaborate menu was served and at its conclusion many addresses of congratulation were tendered the host. Among the speakers, in addition to those mentioned above, were Col. George Pope, chairman of the A. L. A. M. show committee; Alfred Reeves, general manager of the American Motor Car Manufacturers' Association; H. P. Burchall and W. J. Hanley, of the *New York Times*, John C. Wetmore, the dean of the New York automobile press men, and S. M. Butler, chairman of the Contest Board of the American Automobile Association.

NATIONAL GAS ASSOCIATION MEETING

Cincinnati, Jan. 10—It has just been decided by the executive committee of the National Gas and Gasoline Engine Trades Association to hold the next annual meeting at the Sinton Hotel, Cincinnati, from June 13 to 16.

ADJOURNED MEETING OF THE S.A.E.

Agreeably to the resolutions which were made at the first half of the annual meeting of the Society of Automobile Engineers, which was held on the fourth instant, at the Automobile Club of America, the adjourned meeting, which will complete the dual session, will begin to-day at 10 o'clock A. M. in the Engineering Societies Building, New York City, and a banquet will terminate the doings of the society, at which the members and guests will be seated at 7 P. M. at the Engineers' Club, 32 West Fortieth street, New York City.

CANADA GOOD ROADS CONVENTION

Toronto, Ont., Jan. 10—After a conference of a committee of the Ontario Motor League with a similar committee from the Ontario Good Roads Association held in Toronto last week, it was decided to hold a National Good Roads Convention in Toronto during the automobile show, which occurs February 24 to March 3. This show will be the largest ever held in Canada.

OVERLAND COMPANY GIVES LUNCHEON TO PRESS

VERY enjoyable describes the luncheon tendered the "Fourth Estate" by F. A. Barker, of the Overland Automobile Company, introducing John N. Willys, president of the company. The lunch was served at one o'clock on Tuesday, January 11, at the Café Martin, New York City, with the usual good things and all the accessories. It was attended by about fifty representatives of the leading news and trade papers.

At the cigars and coffee, Mr. Barker placed the assembly in charge of A. G. Batchelder, who, in his happy and facetious manner, selected from the gathering the orators of the occasion. In presenting Mr. Willys, in whose honor the gathering was assembled, reference was made to the phenomenal development of the Indianapolis and Toledo properties under his leadership, but the future plans of the company were set forth in substantial and pointed oratory by Mr. Laskar, treasurer of the Lord and Thomas Advertising Agency, in whose hands the Overland company has placed its problem of publicity. His announcement that the advertising for the sale of 20,000 automobiles during 1910 was not to be obtained by free reading notices, was received with applause by an unusually appreciative audience. The advertising campaign will be opened by an expenditure in a single day of $62,000, to be followed by approximately $50,000 a month. It, therefore, followed that aside from an extensive and well-organized manufacturing proposition, the Overland people have organized one of the largest, if not the most elaborate, advertising propaganda in the history of the industry.

Mr. Wagner was then appointed timer, and the speeches following were limited to three minutes each. Complimentary indulgences were then offered by Messrs. Schwartzkopf of *Automobile Topics*, Major Humphreys of the *Post*, Ryan of the Chicago *Record-Herald*, Sullivan and Swetland of The Automobile.

The guests were presented with a handsome souvenir, consisting of a thermos bottle in a leather case filled with good intentions and best wishes for the New Year.

President J. N. Willys, and Banquet Tendered Press Representatives, by Overland Automobile Company, Cafe Martin, January 11

WORK FOR THE A.A.A. LEGISLATIVE BOARD

Widespread demand for uniformity in automobile legislation and the necessity for more satisfactory statutes has been apparent in all sections of the country for several years. The American Automobile Association, through its legislative board, early recognized the necessity for national automobile legislation, and what will be the biggest object lesson ever shown in America toward this end will be seen in Washington next month when the National Legislative Convention will be held in that city. The dates as fixed by the Legislative Board, of which Charles Thaddeus Terry is chairman, will be February 15, 16 and 17.

The American Automobile Association has been working to secure uniformity in automobile laws whereby touring from one State to another could be made possible without the necessity of securing additional registration and paying extra fees, and to a certain extent considerable success has been accomplished along these lines, mainly through the efforts to induce the various State Legislatures to enact uniform State laws. It has remained, however, for this National Legislative Convention to crystallize the efforts made in various sections of the country into a grand national demonstration to secure not only what autoists regard as their rights, but which will be a practical illustration of the growing sentiment for uniformity. As an indication of this increasing demand for uniformity it is important to note that Mr. Terry has been requested to speak before the National Civic Federation at its coming conference on uniform legislation, to be held in Washington January 17, 18 and 19, and he will outline the necessity for federal action.

Mr. Terry has recently announced the members of his Legislative Board for the coming year. Every State in the Union is represented. Among some of the well-known members who have always taken an active part in automobile legislation are T. E. Bryan, Florida; H. O. Smith and Edgar Apperson, Indiana; S. D. Waldon, R. D. Chapin, Michigan; F. T. Staples and C. H. Gillette, Connecticut; Frank C. Battey, Georgia; David Beecroft and Sidney S. Gorman, Illinois; Francis A. Hurtubis, Jr., Robert C. Cooley, J. P. Coghlin, Massachusetts; Frank M. Joyce and C. H. Kohler, Minnesota; Dr. W. B. Richardson, Bert Van Tuyle, H. A. Meldrum, Oliver A. Quayle, and Frank G. Webb, New York; Paul C. Wolff, Robert P. Hooper and Powell Evans, Pennsylvania; W. C. Crosby and H. A. Bonnell, New Jersey; James T. Drought, Wisconsin; C. Gordon Neff and F. T. Sholes, Ohio.

CONTEST AND TECHNICAL COMMITTEES

President Lewis R. Speare, of the American Automobile Association, has appointed the following active and associate members of the Contest Board and of the Technical Committee for 1910:

Chairman—S. M. Butler (previously appointed).

Active Members—David Beecroft, Chicago, Ill.; S. B. Stevens, Rome, N. Y.; T. A. Wright, Wilkes Barre, Pa.; Joseph K. Woods, Newark, N. J.

Associate Members—Frank G. Webb, Brooklyn, N. Y.; Frank B. Joyce, Minneapolis, Minn.; F. C. Donald, Chicago, Ill.; L. P. Lowe, San Francisco, Cal.; C. M. Gillette, Hartford, Conn.; Harry W. Knights, Boston, Mass.; James T. Drought, Milwaukee, Wis.; R. P. Hillman, Los Angeles, Cal.; P. D. Folwell, Philadelphia, Pa.; Ralph W. Smith, Denver, Colo.; Wm. G. Humphreys, Atlanta, Ga.; Harvey Granger, Savannah, Ga.; E. H. R. Green, Dallas, Tex.; Charles B. Shanks, Portland, Ore.; G. P. Bullard, Phoenix, Ariz.; Mason B. McLoughlin, Cleveland, O.; T. C. Campbell, New Orleans, La.; Henry J. Spuhler, Pittsburg, Pa.; Chas. W. Sedwick, Indianapolis, Ind.; Geo. Lane, Detroit, Mich.

Technical Committee—Alden L. McMurtry, Chairman, New York. David Beecroft, Chicago, Ill.; F. E. Edwards, Chicago, Ill.; Henry Souther, Hartford, Conn.; Alex. Churchward, Schenectady, N. Y.

Additional appointments on the Technical Committee will be made covering the Middle West, the Pacific Coast and the Southern territories. The object of further appointments will be to make this committee as representative of the different sections of the country as is the contest board.

MANUFACTURERS' CONTEST ASS'N MEETING

The annual meeting of the Manufacturers' Contest Association, Incorporated, was held Saturday, January 8, at the Hotel Manhattan, New York City. Officers elected were as follows: President, Benjamin Briscoe; vice-president, H. O. Smith; secretary-treasurer, William E. Metzger; assistant secretary-treasurer, Russell A. Field; chairman rules committee, H. E. Coffin; directors, Benjamin Briscoe, H. O. Smith, William E. Metzger, H. E. Coffin and Windsor White.

Reports of officers and committees show the organization to have made splendid progress in the first year of its efforts to regulate contest matters in a manner satisfactory to all concerned. The proposed classifications for 1910 were considered in detail and finally ratified. As soon as adopted by the contest board of the American Automobile Association they will be made public in printed form. Besides members of the organization, several others interested in competitions attended.

Interest in the work of the Contest Association is now evidenced from every corner of the world where motor contests are held. There are already several new applications for membership, and, as stated by the president at Saturday's meeting, "it is plain that every maker interested in contest matters will become identified with the organization," the New York office of which is in the Goodrich building, 1780 and 1782 Broadway.

Among those in attendance at the meeting were:

Members—George H. Strout, Apperson Brothers; Alanson P. Brush, Buick Motor Company; E. R. Hollander, Fiat Automobile Company; H. E. Coffin and C. H. Taylor, Hudson Automobile Company; H. O. Farr, Knox Automobile Company; Benjamin Briscoe and C. W. Kelsey, Maxwell-Briscoe Motor Company; William E. Metzger, Metzger Motor Car Company; George M. Dickson, National Motor Vehicle Company; Howard Marmon, Nordyke & Marmon Company; J. B. Eccleston, Oakland Motor Car Company; J. W. Elmer Pratt, Pierce-Arrow Motor Car Company, and G. W. Weldely, Premier Motor Company.

Present by invitation—S. M. Butler, Chairman American Automobile Association Contest Board; A. R. Pardington, Motor Cups Holding Company; E. A. Moross, Indianapolis Motor Speedway, and Frank Nutt, Haynes Automobile Company.

A.A.A. EXECUTIVE COMMITTEE MEETING

State automobile organizations of Texas and Alabama were added to the roll of the American Automobile Association at the meeting of the executive committee held Tuesday at the New York headquarters. This makes a total of thirty-three State bodies now included in the National association. At the same meeting the Automobile Club of St. Louis, with about 400 members, joined as an unfederated club; it will subsequently be included in the formation of a Missouri State association. Lewis R. Speare presided at the meeting.

The usual reports were made by the chairmen of boards. Thaddeus Terry, who has charge of legislation, indicated that the convention at Washington February 15, 16 and 17 will see important developments in the struggle for National legislation.

Chairman S. M. Butler of the contest board reported that the 1910 competition rules were practically ready for the consideration of the executive committee. The number of applications for sanctions far exceeds any previous list filed this early in the season, though this was to be expected in view of the request of the board that clubs desiring dates should let their wishes be known as soon as possible. Likewise Chairman Powell Evans of the touring board presented instructive facts and figures.

George B. Ellis, president of the Automobile Club of Southern California, and John N. Brooks of the Connecticut State Automobile Association were elected members of the executive committee, and the nominations of the following directors by their respective clubs were also approved: Dr. E. W. Omensetter, North Wildwood, N. J., Automobile Club; Hon. Walter E. Edge, Atlantic City, N. J., Automobile Club; J. J. Hinners, Edgewater-Fort Lee, N. J., Automobile Club; Edward C. Smith, Automobile Club of Vermont; William E. Goucher, Jamestown, N. Y., Automobile Club; J. B. McMurrich, Oswego, N. Y., Automobile Club.

TWO WEEKS OF SHOW FOR PHILADELPHIA

PHILADELPHIA, Jan. 10—Saturday night the ninth annual automobile show of the Philadelphia Automobile Trade Association will open in the Third Regiment Armory, at Broad and Wharton streets. The building is so small that in order to accommodate all the applicants for space an extension of the show for an additional week became absolutely necessary. The first week will be devoted to gasoline and steam pleasure cars only. There are a sufficient number of these exhibits to not only fill every available inch of space, but to necessitate some of the late applicants going over to the second week, when electrics, commercial cars, motorcycles, and accessories will hold forth. A special aero exhibit will be a feature of both weeks.

A large corps of workmen has been engaged since early last week transforming the bare interior of the Armory into a bower of beauty, of which blue and white will be the color scheme. When completed the impression of an outdoor exhibition of automobiles is the effect which the decorators will have produced. Box hedges, lattice-work walls intertwined with flowers and green burlap floorcovering combine to carry out the idea. The aisles will be marked by Corinthian columns topped with vines and ornamental plants. The gallery will be devoted to the use of the local automobile clubs for reception purposes, separate spaces being set apart for the Quaker City Motor Club, the Automobile Club of Philadelphia, the Automobile Club of Germantown and the Automobile Club of Delaware County.

All the exhibiting concerns are members of the Philadelphia Automobile Trade Association. A score or more of non-members have been compelled to take second-week spaces. These, with the electrics, commercials, motorcycles, and accessories, will tax the capacity of the Armory for the last half of the show. The following exhibits will hold the stage during the first week:

Stoyle-Vogel Auto Company—American.
Bergdoll Motor Car Company—Bergdoll cars and taxicabs, Thomas and Mercer.
Chadwick Engineering Company—Chadwick.
Prescott Adamson—Columbia and Reo.
Gawthrop & Wister—Elmore.
Ford Motor Company—Ford.
Locomobile Company of America—Locomobile.
General Motor Car Company—Lozier.
Matheson Automobile Company—Matheson and Everitt "30."
Maxwell-Briscoe Company—Maxwell.
Standard Motor Car Company—Middleby and Velie.
Penn Motor Car Company—Mitchell.
Tioga Automobile Company—National and Hupmobile.
Olds-Oakland Company of Pennsylvania—Oldsmobile and Oakland.
Packard Motor Car Company of Philadelphia—Packard.
Auto Sales Corporation—Peerless and Cadillac.
W. J. Sprankle—Marion and Overland.
Foss-Hughes Motor Car Company—Pierce-Arrow.
West-Stillman Motor Car Company—Pope-Hartford.
The Motor Company—Premier.
Longstreth Motor Car Company—Pullman and Alco.
Thomas M. Twining Company—Regal-Detroit.
Hills Motor Car Company—Royal Tourist.
D. Walter Harper—Stanley steamers.
G. Hilton Gantert—Stearns.
A. G. Spalding & Brother—Stevens-Duryea.
Stoddard-Dayton Auto Company of Philadelphia — Stoddard-Dayton.
Studebaker Brothers Company—Studebaker and Studebaker-Garford.
White Company—White steamer and gasoline cars.
Winton Motor Carriage Company—Winton.

SOME FACTS ABOUT PALACE SHOW

Now that the Palace show has closed, it is possible to present a number of interesting figures and facts in connection with it. All records for attendance, either of the public or of agents, were broken, as were the records for profit as well.

For the six days and seven nights, the total attendance was 104,660, to which total, Friday, the closing day, contributed the greatest amount, 19,000. Owing to the close proximity of the A. L. A. M. show, the latter half of the show was the most profitable, the last three days being equal to the others totaled.

That the dealers were out in force was shown by the large number of dealer's buttons given out by the management, 1,284. In addition to the great number from all over the United States, there were many from Canada, and six from Europe. The attendance of carriage dealers was 243.

Associated with the American Motor Car Manufacturers' Association in the conduct of the show and interested in the profits are the Importers' Automobile Salon and the Motor and Accessory Manufacturers.

At the Grand Central Palace on Saturday, Marcus Nathan, the secretary, said that the palace was built 22 years ago and during all that time it never had such a handsome exhibition, nor one so important in the industrial world, while the attendance exceeded anything on his records. The Palace will not be torn down for at least two years.

SYRACUSE SHOW AN ASSURED SUCCESS

SYRACUSE, N. Y., Jan. 8—Immediately after the close of the New York exhibits, the committee of the Syracuse Automobile Dealers' Association will meet to perfect arrangements for the Syracuse show, to be held March 14-19 in the New York State Armory. Chairman H. D. Van Brunt of the committee says no effort will be spared to make the Syracuse show second to none outside of New York. Double the amount of money spent last year in decorations will be paid out this year.

40,000 SQUARE FEET FOR BUFFALO

BUFFALO, N. Y., Jan. 10—All of the space for the Buffalo Automobile Show, to be held in the Broadway Arsenal February 14-19 under the auspices of the Buffalo Automobile Trade Association, has already been taken. The hall is 267 feet long and 167.1 feet wide, offering a floor area of 35,119 square feet. This is two and one-half times the floor area of Convention Hall where the former shows have been held, so that the forthcoming exhibition will be just that amount larger than any of its predecessors.

Members have been in New York during the past two weeks to visit the shows in Madison Square Garden and the Grand Central Palace for the purpose of obtaining suggestions in the line of decorative effects. A feature already adopted will be the drapery of the vaulted ceiling with the largest American flag ever made. It will form a canopy far above the exhibits, and will be illuminated by electric lamps. The illumination calls for 10,000 lamps. The show will be departmentized, including gasoline pleasure cars, electric vehicles, trucks and motorcycles.

The management is making arrangements also for the exhibition of an aeroplane with an actual record of flight, in the interest of and with the co-operation of the Aero Club of Buffalo.

ROCHESTER LOOKING FOR BIG TIME

ROCHESTER, N. Y., Jan. 10—Under the direction of the Rochester Automobile Dealers' Association and the management of Captain C. A. Simmons, who is well known in Rochester, the third annual automobile show will be opened on February 14, and run to and including February 19. An indication of the spirit in which the show is being received is the fact that the Mayor has consented to postpone a musical concert which was planned to be held in Convention Hall the day previous to the opening. This concert has been done away with in order to permit exhibitors to have all the time necessary to get the hall in complete shape so that when the doors are open on Monday night, February 14, there will be absolutely no reason why the show should not be ready for the public. Monday night will probably witness a tremendously large audience.

Elaborate posters have been put out advertising the show and the preliminary application for spaces on the part of accessories dealers early gave evidence to the manager and the committee in charge that the show would far surpass last year's efforts. It is planned this year that the show in itself will be a big social event, or, rather a series of social events. A special effort will be made on featured nights. From the standpoint of the dealers, more store has been put in this year's show than ever before owing to the success which attended last year's exhibit. An electric display will be a feature.

For months the people of Rochester have been looking forward to this display. This feeling did more to make the manager and committee work hard in the early stages of the preparations to insure success of this year's affair than any other consideration. Features of the affair are to be two bands, one in each section of Convention Hall playing alternately, an elaborate floral display in addition to the musical programs, and electrical illumination.

MILWAUKEE SHOW WILL BE NOTABLE

Milwaukee, Wis., Jan. 10—The Milwaukee Automobile Club has begun to arrange the preliminary arrangements for the second annual show to be held in the Milwaukee Auditorium from February 22 to 27, inclusive, now that space has been sold out and the financial success of the event is assured. The demonstrating cars will be given the use of the Fifth street side of the Auditorium. All three entrances will be used to accommodate visitors. The Cedar street entrance will be used for those who attend in cars and carriages. The State street side is reserved for exhibitors. Electric arches will span Fifth street from Cedar street to Grand avenue.

On the evening of Washington's birthday the show will open and remain open until midnight of Sunday, February 27, in order to give the employes and experts of the various motor car manufacturers in Wisconsin an opportunity to see the exhibition.

The entire ground floor or arena of the main hall will be devoted to motor car exhibits; the basement to trucks, delivery and mail wagons, ambulances and other commercial vehicles; the smaller halls to motor boats, marine engines, sportsmen's goods, and accessories All this has been accomplished in the face of great opposition on the part of the local dealers, a large number of whom have not only refused to exhibit, but have opposed the show.

LOUISVILLE SHOW TO ASTONISH SOUTH

Louisville, Ky., Jan. 10—What will undoubtedly be one of the most pretentious and attractive automobile exhibitions held in this section of the country will be inaugurated in the Armory, said to be the largest building in the South, on March 17, 18 and 19. Applications for space to accommodate cars enough to make a creditable showing have been received and it is evident that the capacity of the Armory will be taxed. The show will be given under the auspices of the Louisville Automobile Dealers' Association and an elaborate plan of decoration will be carried out.

There will be several hundred different displays, which will include an extensive variety of the latest models. The value of machines on exhibition will range from the cheap vehicles to the most expensive cars. In one section of the big building a complete display of motorcycles will be exhibited, while the department of electric pleasure vehicles will be one of the featurs of the show. A considerable amount of space will also be given over to accessories.

At this show the Kentucky people will have the first opportunity to inspect the newest products of representative American makers. Committees have been appointed to take up the work of arranging for the various details of the show, which promises to be the most important event with the automobile manufacturing and trade interests in this part of the country.

DETROIT SHOW DECORATIONS READY

Detroit, Jan. 10—Practically all the decorative effects for the annual auto show under the auspices of the Detroit Auto Dealers' Association, which will open at the Wayne Hotel Gardens Jan. 24, continuing through Jan. 29, are in readiness to be installed, and every indication points to an even more artistic decorative scheme than ever before, making it the beauty show of the country, as well as the leader in point of actual number of models shown. Manager Gillespie and his staff of assistants are busy rounding out the details for the big event, and announce confidently that although the garden will not be available until four days before the show opens everything will be in readiness for the opening night.

ASKS DISSOLUTION OF VOTING POOL

Detroit, Jan. 10—Still another angle to the E-M-F-Studebaker controversy has developed, and may add to the complications already existing. When the selling contract between the two companies was signed last spring seven-tenths of the stock of the E-M-F Company was pooled and placed with the Union Trust Company, with the understanding that it was to be voted in accordance with the instructions of all of the stockholders interested. Having rescinded its selling agreement with the Studebaker concern, the E-M-F Company majority stockholders want the pool dissolved, formal notice having been served on the Union Trust Co. The latter has appealed to the circuit court.

SOUTHERN ENDURANCE RUN IN MARCH

Savannah, Ga., Jan. 10—It has been decided by the Savannah Automobile Club to have the next endurance run, which will be to Jacksonville, Fla., to be run on the 28 and 29 of March. The Savannah *News*, the Jacksonville Automobile Club and a local paper there will also take part. The scout car, a Maxwell to be driven by Robert Brockett, Jr., will leave next week to pick out the route on which the run will take place. It has been figured out that two days will be taken, as on the one to Atlanta. The distance is something like 175 miles. This is but one of the many runs that will be run by the Savannah Automobile Club this coming year.

AUTOCARS TO AUTO CHEMICAL'S RESCUE

Ardmore, Pa., Jan. 10—An automobile "train" as a fire-fighting adjunct was the novel sight witnessed here New Year's eve, when an alarm of fire was received from Wynnewood. The auto chemical responded at once, but its weight was such that progress through the heavy snow was slow, until some one suggested calling on the Autocar people for assistance. A hurry call brought two "testers," which took the heavy chemical in tow and in a trice the "train" was dashing down the Lancaster Pike through the partially broken snow-drifts, reaching the scene of the fire in time to prevent serious damage.

BIG TAXICAB SERVICE FOR BALTIMORE

Baltimore, Jan. 10—The Taxi-Service Company, of Baltimore was incorporated in Trenton, N. J., and under its charter the new concern is permitted to carry on a general taxicab and garage business; to transport merchandise as well as passengers and to manufacture and deal in vehicles for conducting its business. The new firm takes over Stewart & Company's livery business, including taxicabs, horses, carriages, etc. The Taxi-Service Company has an authorized capital stock of $500,000 divided into 5,000 shares of a par value of $100. Of this sum, $250,000 is preferred stock bearing 7 per cent. cumulative dividends, and the remainder is common stock. Prominent Baltimore financial interests are behind the new enterprise. The plans include the addition of a considerable number of cabs to those in service, with the object of giving Baltimore a service second to none.

Four Shaft-Driven Baker Electrics Out for a Winter Run

Pittsburg's New Traffic Regulations—Pittsburg has experimented one week with the new rule of the police department that all vehicle traffic should proceed in certain directions on leading downtown streets. Everything goes north on Smithfield street and south on Wood street, and the same order will probably be observed a little later on Liberty and Penn avenues, which are parallel with each other and nearly parallel with Wood and Smithfield. It is the intention also to do away with all vehicle traffic during the day on Fifth avenue, between Grant street and Liberty avenue. So far, the change has been received with comparatively little objection, and aside from a few collisions and altercations the first day the order went into effect, it has been welcomed as a sure means of doing away with the fearful downtown congestion.

Royal Equipment Company, Bridgeport, Conn.—This company, established by the late Arthur H. Raymond in 1902, has been reorganized. The new company will be known as the Royal Equipment Company, with a capital stock of $50,000 that has been fully paid. The officers of the company will be E. B. Knowles, president and treasurer; L. V. Raymond, vice-president, and W. G. Hoag, secretary. Mr. Knowles was formerly Mr. Raymond's confidential adviser and business manager, while Mr. Hoag was associated with the founder of the company in the first years of its establishment. The new concern begins business in a factory five times as large as that previously occupied.

Brampton Aeroplane Chains—Chas. E. Miller, 97-101 Reade street, New York, who is the sole United States agent for Brampton chains, has just received from the factory in England samples of a special chain which Brampton Bros. are now making for aeroplanes. This chain is made of nickel steel, and of a special size long pitch and a very narrow link, the size being 1¼-inches pitch, 5/6-inch wide. It is made specially loose, allowing a certain amount of lateral flexibility, which is desirable for the purpose for which it is used. This size chain was designed for and is used on the "Cody" biplane. Mr. Cody, an American, is in charge of the aeronautic division of the English Army.

Parts Exhibition.—At the headquarters of the Rambler Automobile Company of New York, during first show week, there was shown a stock of duplicates of every part of every Rambler car manufactured in the Rambler factory since the factory was started—ten years ago. The importance of being able to purchase an extra part with ease and dispatch has neevr been fully realized by new purchasers of automobiles, but always considered of great importance by people who have owned cars. The New York exhibit made by the Rambler representatives illustrates what has been accomplished by Thomas B. Jeffery & Company in this respect within the last ten years.

An Interesting Feature—To demonstrate the qualities of the Truffault-Hartford shock absorber, its manufacturers utilized a unique device at the Grand Central Palace Show. Two miniature automobiles, perfect in detail and complete equipment, including extra tires, electric headlights, tool boxes, etc., were shown in comparison, running on a rough road at a speed of about thirty miles an hour, one of the cars being fitted with shock absorbers, while the other is not. It was plainly seen that the passengers in the car with the shock absorbers found it always "easy going," while the occupants of the other car were having a rather rough time of it.

Ford Motor Company Gives Christmas Gifts—Following an established practice, the Ford Motor Company distributed about $80,000 among the workers in their big plant—this as a token of appreciation for faithful service rendered during the preceding twelve months. While the bulk of the money was distributed in Detroit, it still remains that all the branch offices and factories were remembered, so that Ford employees in twenty cities between New York and Seattle, as well as in Paris, France: Melbourne, Australia, and Winnipeg, Canada, were all remembered. The money was divided according to years of service.

Rambler Leads in Minnesota—Figures just compiled for the State of Minnesota show that there are in use in that State 6,282 automobiles. It is interesting to note that a very large number of these cars have been purchased by residents of small towns. The compilation shows that in towns of under 1,000 population there are in use 1,169 automobiles, while in towns between 10,000 and 21,000 population there are only 252 automobiles. Thomas B. Jeffery & Co. say that the New Rambler leads all those within $1,000 of its price in towns under 1,000 population, as well as in towns under 3,000 and 5,000 population.

Franklin Owners First and Third—The automobile owners of Ohio are required to take out a State license each year, and among the 23,000 motorists in that State there is rivalry for the low numbers. For months ahead application was made last year for certain numbers to be given when the tags were sold for the new year. The distinction of carrying No. 1 for the year has fallen to Thomas B. Paxton, Jr., a lawyer of Cincinnati, who owns a Franklin automobile. No. 3 has been secured for another Franklin by E. M. Schoenborn of Columbus, president of the Columbus Baseball Club.

Franklin with a Glass Hood—George E. Messer, Syracuse, N. Y., branch manager for the Franklin Automobile Company, is driving about the streets of that city with a Franklin motor car equipped with a hood made of glass instead of metal. The interior of the hood is illuminated by means of a series of electric lights. When standing in the city streets, especially in the evening, the car is always surrounded by a crowd of interested onlookers. The engine is, on occasions like this, allowed to run while car stops are made, so giving a visual demonstration of the operation of the motor.

To Share Company Earnings—The Warner Gear Works of Muncie, Ind., have joined the ranks of that class of manufacturers who believe that employees should share directly in the company's profits, and at a recent meeting an appropriation was made for distribution among employees who have completed three distinct periods of service. The plan was proposed by president A. L. Johnson, and the board of directors fell in line with the idea. It is expected that this move will encourage or increase the efficiency of the organization very materially.

Sebring "Six" Makes Record—In a recent test the Sebring "Six" was driven from Sebring, O., to East Liverpool, O., without a change of gears. The president of the Sebring company ordered that it be driven full speed over the intervening hills, and to be sure that the speed lever was not changed the car was wired into high speed. R. M. Allen drove, accompanied by B. H. Sebring. The gear was not changed during the trip and the "Six" took all of the bad hills without the least difficulty, evidently having plenty of power in reserve at all times.

Long Manufacturing Company, Chicago—This maker of radiators and accessories has just bought a tract of land in Detroit fronting on Cass avenue 320 feet and extending from Amsterdam to Burroughs avenue, and plans have been prepared for a two-story modern plant with 100,000 square feet and employing 1,000 men. The new plant at Detroit will be operated as a branch of the main plant in Chicago. The capital of the company has been increased to $300,000. J. B. Long is president and treasurer and Louis Shisler secretary.

Interesting Times Square Co. Exhibit.—This New York company, extensive dealers in second-hand machines, has a comprehensive collection of cars, ranging from the small runabout to the great sightseeing 'bus, of all cylinder equipments and all motive powers, whether gasoline, steam or electricity propelled vehicles. The showrooms, located at 213 West Forty-eighth street, are commodious—each car being readily accessible—while the lighting facilities are good, permitting minute inspection.

Special Cars for Automobiles—The Chicago, Burlington & Quincy Railroad has followed the lead of the Milwaukee road in furnishing special freight cars for shipments of motor cars, and it is reported that an order for 500 has been placed with the Burlington's shops for early spring delivery. The West Milwaukee shops of the Milwaukee road are still building these special cars, Wisconsin motor car manufacturers having become partial to them since first being granted their use.

Iroquois Garage Company, Columbus, Ohio—This concern recently incorporated in Columbus, Ohio, with a capital stock of $20,000, taking over the Columbus Garage & Machine Company of that city. The new company contains many of the men interested in the old one, and the management will not be changed. H. L. Thurma is general manager. The Iroquois Garage Company, in addition to the garage business, will be central Ohio agents for the Empire and Grabowsky trucks.

Owen-Thomas Company Moves—The Corliss Motor Company, of Corliss, Wis., is moving the machinery and equipment of the Owen-Thomas Motor Car Company, of Janesville, Wis., to Corliss, where it is being installed in the plant of the Wisconsin Engine Company. This plant will be used until the new works can be erected. The Wisconsin Engine Company is building the motors for the new car, which will be a six-cylinder, 60-horsepower, of all-steel construction.

Sheriff Gets a Franklin—A 1910 Model H Franklin car has been purchased for the sheriff of Milwaukee county, Wisconsin, by the board of supervisors. The car is of seven-passenger capacity, with a 6-cylinder, 42-horsepower motor, weighing 3,000 pounds. The price is $4,000, fully equipped. The sale was made by the Franklin Automobile Company. Fourth and Prairie streets, Milwaukee. The city now has 12 automobiles and the county three.

Demot Runabout Goes "Cross Country"—In order to demonstrate that the Demotcar is not only an asphalt performer, but a good "rough road" proposition as well, Albert K. Peters and W. C. Corey, of the Harper Aldrich Company, Detroit, drove from that city to Port Huron, over roads representing about every disreputable stage; time, 2 hours and 40 minutes; distance, 62 miles. The car finished in good shape.

Smith Automobile Company, Grand Rapids, Mich.—Plans are under way to remove this plant from Topeka, Kan., to Grand Rapids, Mich. Of the $180,000 in stock of the company, 17 Grand Rapids business men have acquired a controlling interest, and it is said that as soon as legal formalities are complied with, work will be commenced on the local factory. It is planned to have 500 cars for future delivery.

New Transfer Company—The Canfield Transfer Company, just organized, will conduct an auto passenger business and transfer business between Canfield, Ohio, and Youngstown, Ohio. It is possible that later a mail route may also be established over this line. The company was organized by H. W. and Bertha Corll, C. H. and Melvin Neff, and Lola E. Mock, of Canfield, Ohio. The capital stock is $50,000.

Another Carriage Company Comes In—The Collings Carriage Company of Philadelphia, old established and conservative, will take on a line of automobiles, selecting the Rainier. The Atlanta Gold Trophy Car, which made a new record of 200 miles in 173 minutes, will be placed on exhibition in the Collings showrooms, 1719 Chestnut street. This in addition to several other models.

Stewart Taxi Service Company, Baltimore—This organization has been incorporated under the laws of Maryland, with a capital stock of $10,000. The incorporators are: Harry L. Stewart and T. Foley Hisky, of Baltimore; Harlan W. Whipple and James J. O'Brien, of New York, and Claude S. Jarvis, of Philadelphia. Other New Yorkers are Lawrence W. Barnum and William S. Stafford.

Pittsburg Automobilists Up In Arms—The automobilists in Pittsburg are much enraged over the fact that a bill is now pending in Congress, imposing a tax of $10 upon all automobiles traveling from one State into another. They argue that such a bill, if passed, will limit the excursion business to local States—also that it will work a great injury to hotel interests all over the country.

Important Executive Change—Clare A. Pickard, president of the board of directors of the Salisbury Wheel & Manufacturing Company, is no longer connected with this concern. S. H. Penfield has been appointed his successor, while Edwin D. Cook has been made vice-president of the board of directors to fill the vacancy caused by the appointment of Mr. Penfield.

A Milwaukee Move—The Kissel Kar Company, of Milwaukee, distributors in a large Western territory for the Kissel Kar, of Hartford, Wis., has moved from Fourth and Poplar streets (Motor Row) to 228-232 Wisconsin street, Milwaukee, into the quarters formerly occupied by G. W. Browne Motor Company, recently merged with Bates-Odenbrett Auto Co.

Correction as to Quantity—In an item occurring on page 1194, of THE AUTOMOBILE issue of December 30, with reference to the output of the Warner tops, there was a notice in effect that this company expected the output to be "1,000 tops." By way of correction be it stated that this should have read "10,000 tops." We make this correction in justice to all.

Midland Rubber Company of Columbus—This concern incorporated in Columbus, Ohio, with a capital stock of $25,000 to manufacture and sell rubber appliances. A part of the output will be designed for the automobile industry. The incorporators were Fred W. Hoeschele, John L. Hoeschele, Fred A. Caskey and H. J. Powell.

New Reo Bucks the Snow—A new model, four-cylinder Reo went through the recent snow blockade from New York to Spring Valley, N. Y., a distance of 50 miles, over roads which had not yet been broken. H. D. Hewlett, driver and owner, states that he arrived home with the car in splendid condition, minus trouble and delay.

General Motors Company of Detroit—It is announced that this company has incorporated in Michigan. The incorporation is for $10,000, with W. C. Durant, Flint, W. J. Mead, Lansing, and C. R. Hathway, New York, each owning one share of stock. C. R. Hathway, Trustee, owns the other 97 shares.

Motor Parts Company, Chicago—The removal of this company is noted, from 309 Fisher Building, Chicago, to 1735 Michigan avenue, the same city. This company is selling agent for the Providence Engineering Works, and for the National Porcelain Company. R. E. Hardy is president.

Direct Drive Mfg. Co., Indianapolis, Ind.—This concern has been organized with paid up capital of $50,000, to manufacture the Parkinson direct-drive transmission. The officers are: W. H. Parkinson, president; B. F. Meixell, general manager; A. C. Downing, secretary and treasurer.

Racine to Keep Big Plant—It is said that the Racine, Wis., Manufacturing Co. will not move to another city, Racine manufacturers and merchants having offered to subscribe a fund of $100,000 to assist the company in rebuilding the plant destroyed by fire on Dec. 12.

Pennsylvania Rubber Company Elects Directors—At a recent meeting of the stockholders of this company, the following were elected directors for 1910: Herbert Du Puys, H. Wilfred Du Puys, Chas. M. Du Puys, F. A. Wilcox and Seneca G. Lewis.

Still Doing Business—The plant of the King Automobile Tire Company, at Racine, Wis., was damaged $3,000 by fire on January 1. The production will be carried on as usual, new equipment having been installed.

IN AND ABOUT THE AGENCIES

E.M.F. and Flanders "20" in Columbus—These cars will be represented in Columbus, Ohio, by a $20,000 corporation headed by Foster G. Burdell. The territory covered consists of Franklin, Madison, Pickaway and Delaware counties. The incorporators are: Foster G. Burdell, H. M. Myers, Randolph Walton, G. S. Frambes and P. D. Newall. The officers are: F. G. Burdell, president and general manager; H. M. Myers, secretary and attorney, and P. B. Newall, treasurer.

E-M-F and Flanders, Philadelphia—J. C. Schwartz is president, J. E. Gomery secretary-treasurer and Frank Yerger technical manager of the new company which will represent the E-M-F and Flanders cars in Philadelphia. Temporary offices have been opened at 1229 Chestnut street, but when the concrete building now in course of erection at Broad and Callowhill streets is completed, about February 1, the new concern will establish its quarters there.

Franklin, Cincinnati and St. Louis—The Franklin Automobile Company, which maintains branches for the sale of automobiles made by the H. H. Franklin Manufacturing Company, of Syracuse, has announced the opening of branches in Cincinnati and St. Louis. Mr. Braerly, formerly branch manager of the Olds Oakland Company in Toledo, has charge of the Franklin interests in St. Louis.

Winton, Marion, Overland in Milwaukee—The Bates-Odenbrett Auto Co., 503-507 Broadway, Milwaukee, Wis., representing the Winton, Marion and Overland, is making extensive improvements in its garage and salesrooms. New offices have been established, giving more stock room. The company recently absorbed the George W. Browne Co.

Isotta, Simplex and Pennsylvania, Philadelphia—Failing to secure adequate space at the coming Philadelphia Show, these cars will have a two weeks' show of their own in their quarters on the southwest corner of Twelfth and Walnut streets, Philadelphia. J. M. Quimby & Company, at the above address, are the local agents.

Studebaker, Portage, Wis.—The Cook-Jones Auto Company has been organized at Portage, Wis., to handle the Studebaker gasoline and electric cars. A livery and accessories department will also be established. James R. Jones was for several years associated with the Hokanson Automobile Company, of Madison, Wis.

Continental Tires, Cleveland and Denver—The Continental Caoutchouc Company has added two more distributing agencies to its list. These are the Pennsylvania Rubber and Automobile Company, 145 Euclid avenue, Cleveland, and the Boss Rubber Company, 1614 Broadway, Denver.

Lavalette & Company, New York—This concern, makers of the Eisemann Magneto, have removed from 112 West 42d street to more extensive quarters in the new Stoddard-Dayton Building at 57th street and Broadway, New York. This concern will occupy the entire sixth floor.

Another Foreign Agency—Flandrau & Company, well-known as carriage builders, have taken the exclusive selling agency in the United States for the Brasier car, built by the Société des Automobile Brasier, Paris. These cars will be equipped exclusively with Michelin tires.

E-M-F, Wilmington, Del.—This company will be represented in Wilmington, Del., by the T. C. Bradford Company. Wilmington is the center of the selling territory, comprising the State of Delaware and the eastern shore of Maryland, over which there has been a dispute.

R. E. Hardy Company, manufacturers of ignition plugs and other accessories, will move from their present location in New York City to Chicago, Ill. They will occupy a floor at 1735 Michigan avenue. Their location is in the center of Chicago's "Gasoline Row."

Early Motor Car Company of Columbus—A change is noted in that this company, organized by Dr. L. M. Early some time ago, has taken the Central Ohio agency for the Paterson car made at Flint, Mich., in addition to the Rambler and Babcock electric.

Ford Agency Change in Pittsburg—Paul Brown Patterson and Dr. J. M. Emery, of New Castle, Pa., have formed a partnership and have taken over the Ford agency in Pittsburg. They will be located at 135 Pittsburg street.

McIntyre, Winston-Salem, N. C.—The Motor Company of this city has secured the State agency for the automobiles and delivery wagons of the W. H. McIntyre Company of Auburn, Ind.

Mitchell Cars, Clarksburg, W. Va.—The Clarksburg Automobile Company, Clarksburg, W. Va., will handle these cars in the future. This company has been recently organized.

Hess-Bright Bearings, Chicago—The Hess-Bright Mfg. Co., of Philadelphia, will open a Chicago branch at 1800 Michigan avenue about January 20 to care for its Western trade.

Cole "30," Columbus—John T. Gill has secured the agency for this car in Columbus and surrounding territory. He will be associated with the Love Garage Company.

Pierce, Racine, Wis.—D. Elmer Roberts, of Racine, Wis., has established a local agency for the Pierce Motor Car Co., of Racine, at Wisconsin and Fifth streets.

Mitchell, Kewaunee, Wis.—W. Heck, of Kewaunee, Wis., has been appointed a district agent for the Mitchell in several counties of northern Wisconsin.

PERSONAL TRADE MENTION

W. McK. White, formerly associated with the Grand Central Palace Show, will leave for Indianapolis February 1, where he will enter the advertising and selling department of the Premier Motor Manufacturing Company. He will be associated with President H. O. Smith. Mr. White has been in the automobile trade for a number of years and has been prominently identified with the sales departments of several well-known manufacturers. He has also done editorial work for the *Press* and *Evening Times* in Philadelphia and was later connected with the staff of The Automobile.

A. L. Garford, of Cleveland, gave a luncheon last Thursday noon at the Engineers' Club to the old Federal Mfg. Company producers, including besides A. L. Garford, the host, M. B. Johnson, A. O. Smith, L. M. Wainwright, D. B. Warwick, W. W. Wardrop, W. L. Colt, J. M. Sinyard, L. D. Bolton, W. P. Culver, F. W. Lawrence, T. J. Heller, Herman Ely, F. M. Germane, E. K. Moore and G. J. Leonard.

John A. Poole, formerly associated with Col. Albert A. Pope, and European traveler for the American Bicycle Company, later sales manager of the Olds Motor Works and Buick Motor Company, has formed a connection with the Babcock Electric Carriage Company. Mr. Poole has been appointed general sales agent for the Babcock.

Elmer Apperson, president Apperson Brothers Automobile Company, Kokomo, Ind., according to latest reports, is convalescing at Lakeview Hotel, Leesburg, Fla. His absence from the Garden Show caused no little comment, as it is the first he has missed since the first show was held in the Garden in November, 1901.

H. E. Doty, fo merly sales manager of the Southern half of the Western sales department of the White Company, has been transferred to San Francisco, where he will assume the position of assistant manager of the Pacific Coast department. J. O. Sackman, of the Chicago office, has succeeded Mr. Doty.

J. J. Fuerth has opened a training school for chauffeurs and car owners in Syracuse, N. Y. A corps of competent instructors have been engaged for the purpose of teaching the manipulation, construction and repair work of cars. Mr. Fuerth was formerly from New York.

Louis C. Block, manager of the Philadelphia branch of the Ford Motor Company, who has been in Cincinnati for the past two months establishing a branch house, returned to the Quaker City last week.

Hans Renold, proprietor of the great chain works employing 1,000 men in Manchester, England, and bearing his name, is at the Manhattan, New York City. Herr Renold has done much in developing chain transmission.

James F. Fairman is now connected with the Automobile Tire Company, Inc., with headquarters at 1625 Broadway, New York.

F. L. Gallagher, secretary and treasurer of the Modern Tool Company, Erie, Pa., died on November 29.

THERMOID RUBBER COMPANY ENTERTAINS

On December 30 the Lozier Motor Company was entertained by President Stokes of the Thermoid Rubber Company, at a dinner given in the apartments of Mr. Stokes in the Hotel Royalton, New York. The dinner, while not large, is said to have been one of the finest ever served in the greater city. On this occasion the Thermoid Rubber Company presented the Lozier Motor Company with a beautiful and most remarkable tablet executed by Peter Korzilius, a sculptor of note. This tablet, which measures three feet in height and five feet in length, shows the two Lozier cars in action, winning the great 24-hour race at Brighton Beach on October 15. They were reproduced from actual photographs of the race. It will be remembered that in this race the Lozier car No. 3 finished in first place, establishing a new world's record of 1,196 miles. The dinner was evidently an expression of mutual good will, inasmuch as the Lozier Company were strong in their acknowledgment of the efficiency of Thermoid Brake Lining, and gives it due credit for the part it played in the winning of this important victory.

TREND OF THE TIMES IN OHIO

Columbus, O., Jan. 10—Automobile sales companies, garages and motor supply houses are being formed in every part of Ohio. The records of the Secretary of State show that many concerns were incorporated during the past week as follows:

The Automobile Trucking & Delivery Company, Cleveland, $15,000, by B. R. Graham and others.

The Mauser Auto Cab Company, Youngstown, $5,000; Louis K. Mauser and others.

The Zumstein Taxicab Company, Cincinnati, $300,000; Charles S. Dale and others.

The Automobile Country Club Company, Bevis, Hamilton County, $50,000; John Hamilton Davis, W. H. Hilland, John M. Thomas, Jr., Robert J. Buckwater and Theodore Jung.

The Atlas Motor Car Company, Cincinnati, $10,000; Hans Richards, Mrs. H. D. Braun, Mrs. F. B. Williams, Oscar Hood and Harold Becket Gibbs.

The Anchor Motor Car Company, Cincinnati, $50,000; W. J. Brunsman, F. M. Blair, Morris J. Dale and others.

AUTOMOBILES BOUGHT and sold, 20th Century Automobile Co., 1615-23 B'way, corner 49th St. 'Phone 4767 Col., New York.

AUTOMOBILE BARGAINS!! We are the largest dealers in the world in new and used cars. Now is the time to snap up the bargains. Hundreds of private owners, anxious to dispose of their 1908 and 1909 cars without delay, chiefly on account of getting 1910 models, have sacrificed them to us, and we, in turn, after being most careful to accept only good cars and then putting them in first-class condition, offer them at surprisingly low figures. We have them in all sizes and makes from the smallest to the largest. The makes creditably represented in the big stock on our sales floors are: Packards, Thomas, Peerless, Pope-Hartford, Stevens-Duryea, Haynes, Buicks, Hotchkiss, Pierce-Arrows, Oldsmobiles, Mitchells, Locomobiles, Chalmers-Detroit, Winton, Fords, Cadillacs and other well-known and reliable makes. Buy now and get more than your money's worth, and remember it costs you nothing to investigate. Send for our Bulletin containing prices and description of hundreds of cars. Times Square Auto Co., largest dealers in the world in new and second-hand cars. New York, 215-217 W. 48th St.; Philadelphia, 238-40 N. Broad St.; Chicago, 1332-14 Michigan Ave.; St. Louis, Pine and 18th Sts.; Kansas City, 1701-3 Main St.

BARGAIN—If you wish to purchase a 50-H. P. car at a very reasonable figure, communicate with Mr. Charles T. Brown, Winchendon, Mass. Any kind of a demonstration gladly given.

BARGAINS in second-hand cars. Winton touring car, newly painted and overhauled, $700; Peerless touring car, overhauled, all new tires, $650; Maxwell two-cylinder touring car, in good condition, $550; Ford Model T tourabout, run very little, $700; two Cadillac touring cars, single cylinder, $300. Address L. T. Ford, Sanford, Maine.

BUICK, Model 17, '09; run 1,742 miles; top, wind shield, slip covers, speedometer, three tubes and new extra casing; all good as new. Demonstration. Also two-cylinder Autocar delivery. White Steamers, '06, '07 and '08. For best offer. S. A. Teel, Bangor, Pa.

CORBIN touring cars and runabouts, $800 and up. Thoroughly overhauled by us and guaranteed. Corbin Motor Vehicle Co'p'n of N. Y., 1888 Broadway, near 62d St., New York City.

FOR SALE—Single-cylinder Cadillac; also small cylinder Northern runabout, in good order, or exchange for larger car. Box 431, Stratford, Conn.

GREATEST automobile sale in New York—Over 200 cars, all sold direct for owners; no dealers' profit to pay. Cars sold just as they come from owners. Unlike others, we do not put a few dollars in paint and repairs and add hundreds to the price. Our stock includes limousines, touring cars, roadsters, runabouts and delivery wagons. Prices, $125 to $3,500. A number of cars sold for unpaid advances and storage charges. The house of genuine bargains—one-third less than Broadway prices. Manhattan Storage Co., 334-340 West 44th St., near 8th Ave., New York City.

HOLSMAN, 1908 Model, high-wheel runabout, equipped with top and newly painted, $200. Lyman Kirkpatrick, Rochester, N. Y.

THE AUTOMOBILE

QUAKER CITY'S SHOW OPENS AUSPICIOUSLY

Third Regiment Armory, Where the Philadelphia Show Is in Progress

PHILADELPHIA, Jan. 15—The ninth annual show of the Automobile Trade Association of Philadelphia, in the Third Regiment Armory, was declared open to the public at 8 o'clock this evening without any ceremonies. The first bar of the overture by the Third Regiment Band was the only signal. At the opening hour the aisles were crowded uncomfortably; an hour later progress at a rate faster than a snail-like crawl was impossible. It was the biggest opening night in the history of the Quaker City's automobile shows, and this despite the fact that the present show building is considerably smaller than some in which former shows have been held. "Evening clothes" were numerous, and Fashion seems to have set the stamp of approval on this annually recurring winter fixture.

Heavy snowstorms on Thursday and Friday delayed the arrival of several of the out-of-town exhibits; others are to come entire from the Madison Square Garden show in New York. Monday midday, however, will see the cars assigned to the first week of the show all in place; after that hour General Manager Beck says that no cars shall come in or go out—they are there to stay till Saturday night, when there will be a general revamping of the floor-space to make room for the second week's contingent of exhibits.

At 4 o'clock this afternoon it would have taken an optimist of the purest ray serene to predict anything better than 50 per cent of completeness in the preparations at the opening hour. But the committee, with Manager Beck at its head and assisted by members of the association, began a systematic clearing up of the floor, and by side-stepping supper they were enabled to get the building in fair shape for the opening. Save for a few bare spots here and there, where exhibits had failed to arrive, the general effect was that of a complete exhibition.

The crowd was so dense that no particular portions of the exhibition could be selected as centres of interest. Those exhibits, however, which included torpedo bodies among their models seemed to be especially interesting to the visitors, and the attendants at those booths were kept busy all the evening explaining the beauties of this latest novelty. Of the forty separate makers of cars exhibited at the thirty booths, twenty-eight are of the four-cylinder variety, the six-cylinder type claiming twelve representatives. The only two-cylinder motors to be exhibited are installed in the Autocar truck, which will be shown during the second week.

The Show Committee is composed of J. A. Wister, chairman; James L. Gibney, W. J. Foss and General Manager J. Henry Beck, with Richard H. Kain as publicity man. All former efforts of local promoters in striving after superior decorative effects have been outclassed by the splendid combination worked out by Decorator Charles M. Simpson. The main color scheme is blue and white. Overhead and along the front and side walls this combination prevails, the panels on the walls being punctuated at intervals by Corinthian columns of pure white extending to the roof, the ugly beams and braces of which are hidden from view by graceful festoons of blue and white bunting, the former representing heaven's blue vault, the white the fleecy clouds.

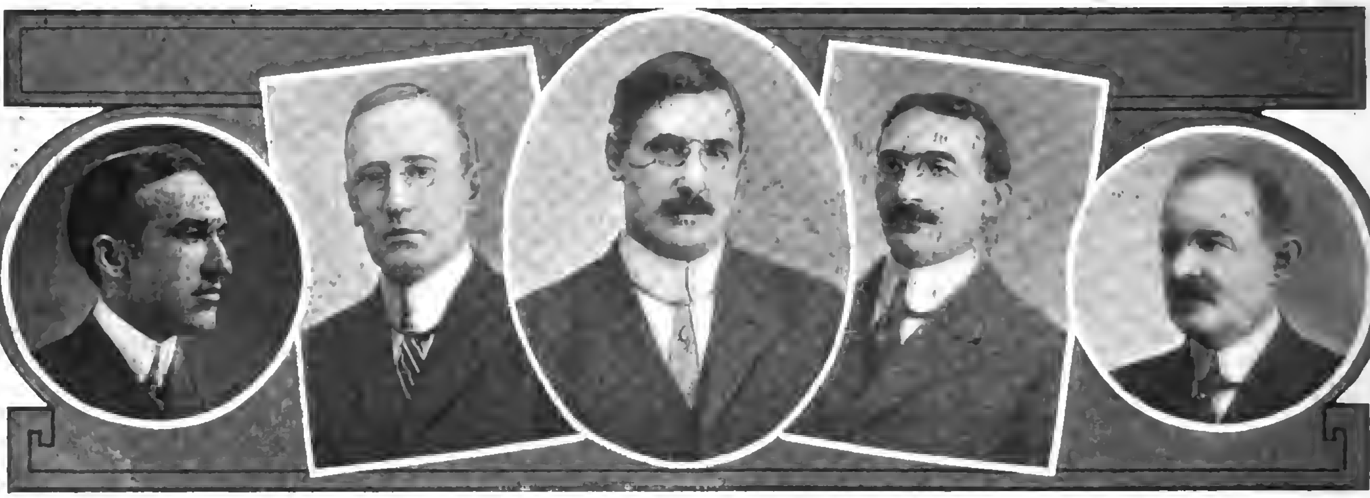
The entire back wall of the armory is taken up by a startlingly original and effective sunburst, the rays of which are made up of scarlet, orange, yellow and white bunting, the sun being represented by a huge gilt ball on which is spread the simple legend "1910."

The three aisles are marked on either side by rows of Carrara marble columns, each surmounted by a Swiss chalet in miniature and filled with growing plants. Each pair of columns is connected by a graceful trellised arch extending over the aisle, the intertwined flowers in which help along the outdoor-garden effect which the designer had in mind. Box hedges separate the various exhibitors' spaces, which are marked by dark green rustic signboards set at an angle on 12-foot uprights of the same color. The lettering on the boards is silver-white, and contrasts well with the dark background. The carpeting of dark green carries out the lawn idea, the outdoor effect being still further added to by the dark green rustic benches and chairs at each booth.

The lighting is especially well done. Thirty big arcs, the same number of Welsbach clusters, with countless long festoons of white electric bulbs, setting for the beautiful decorative effects to excellent advantage.

To-night's opening saw several of the exhibits incomplete, some of the cars to be displayed being at the Madison Square Garden show, and will not be installed until Sunday afternoon. When the doors are thrown open at noon on Monday there will have been crowded into the armory 123 complete cars and 21 chasses. On the opening night the crowded condition of the majority of the displays, with the crowd surging through the eight-foot aisles and encroaching onto the working ground of the conversation artists connected with each booth, again brought forth the wail, "When will Philadelphia have a convention hall of suitable size to house an affair of this kind?"

The decision to run the show for two weeks was actually forced on the committee by their inability to secure an exhibition building anywhere near the dimensions required for the annually increasing size of the show. The Second Regiment Armory, the largest building of the kind in the city, could not be engaged this year owing to the structure having been taken over by the State of Pennsylvania, a law of the commonwealth preventing the renting of any of its property for any purpose whatever. The First Regiment's quarters, although ideally located, was out of the question, being entirely too small. This process of elimination left the Third Regiment Armory as the only available building in the city. The main drill floor measures but 172 x 144 feet. With less than fifteen thousand square feet at their disposal, including aisle space, and with more would-be exhibitors of pleasure cars alone than could be accommodated, the show committee hurriedly decided to run the exhibition for two weeks, the first to be devoted to pleasure cars alone, the second to commercial vehicles, electrics, motorcycles and accessories. Even this arrangement did not provide sufficient space for the pleasure car exhibitors, and a dozen or more of them will be relegated to the second week. In assigning the space, of course, the preference was given to the members of the Philadelphia Automobile Trade Association, who are bearing the brunt and burdens of the management of the exhibition. Most of the exhibitors who failed to get in with the first week's elect have taken the situation philosophically, being well aware of the impossibility of satisfying everybody as to space and location.



W. J. Foss J. H. Beck J. A. Wister J. L. Gibney R. H. Kain

The Local Show Committee That Is Making the Exhibition a Success

Suspended from the armory roof is a new Herring-Curtiss aeroplane, natty in its bright varnish, looking fit for a dash through the bunting sky and clouds above it. So far this constitutes the only item in the "auxiliary aero exhibit," but it is understood that several additions will be made to this branch of the show before the end of the first week.

The management has made a hit by setting apart certain portions of the first balcony for the use of the various local clubs—the Quaker City, Philadelphia, Germantown, Century, and Delaware County. These were thronged throughout the opening night by the club members and their ladies—the balcony is a famous vantage-point from which to look down upon the crowds below and get a bird's-eye view of the whole scene. The "private boxes," as it were, will be devoted solely to the use of the members and friends of the clubs mentioned during the two weeks of the show.

Aside from the size, there is nothing to distinguish one booth from another except the wording on the signs. Uniformity is rigidly preserved, and no extraneous decorations have been allowed. Some of the displays are of a magnitude worthy of a national show. The Packard, Chadwick, Peerless and Cadillac, Locomobile, Olds and Oakland, Pullman, Elmore, White, Winton, Stoddard-Dayton, Columbia and Reo, Premier and Bergdoll dis-

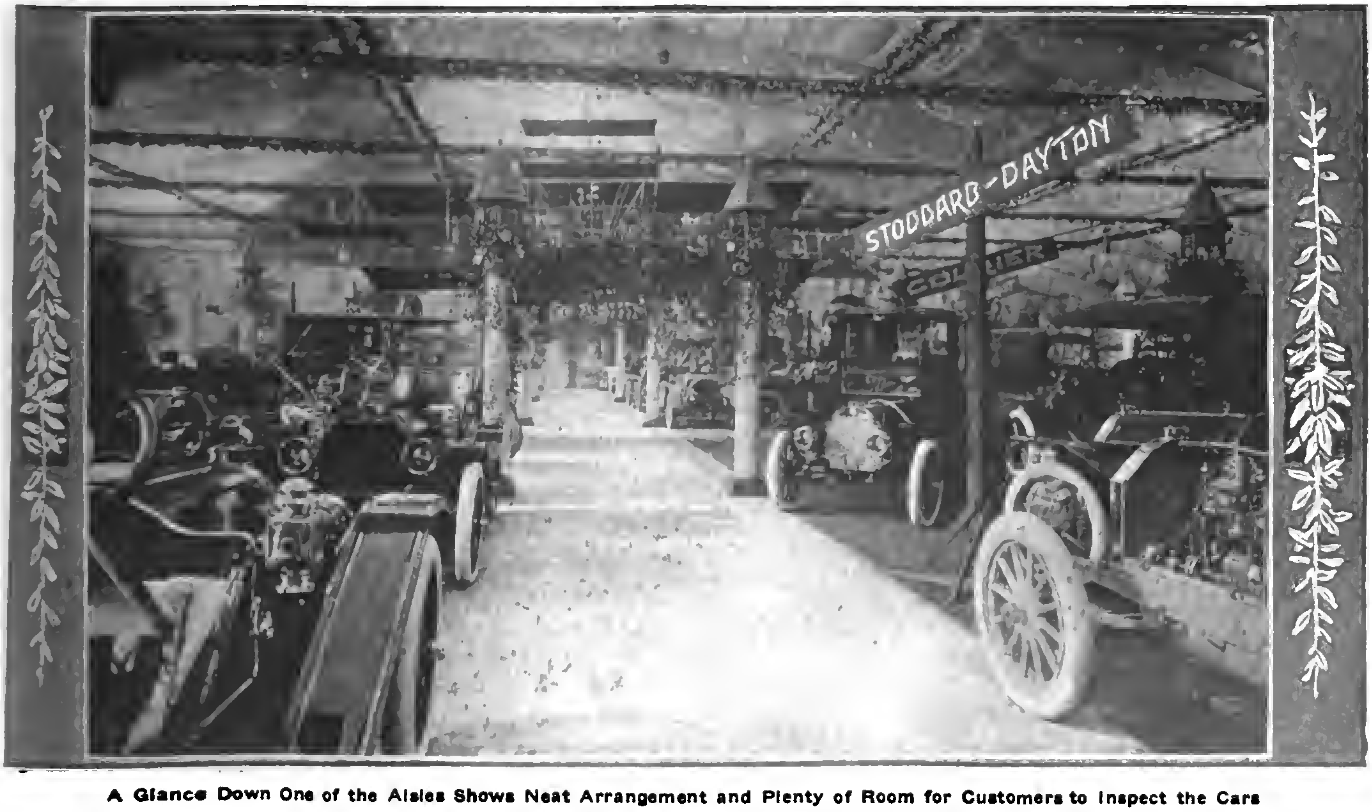
Auditorium Where the Exhibits Are Tastefully Arranged and the Decorations Are Harmonious in Effectiveness

plays occupy space to the limit allowed by the committee. In point of the number of cars exhibited the Ford display is especially prominent with two touring cars, a T-roadster, a town car, a landaulet and a coupé, all model T's. The Olds-Oakland display includes four each of the Oldsmobile and the Oakland—two touring cars, roadster and landaulet of the former and two touring and the same number of roadster models of the latter.

Another most comprehensive display is that of the Maxwell-Briscoe Company, no less than six cars being crowded into the rather limited space—Model E and Model G touring cars, three Model Q's (touring car, runabout and the famous "Sportsman"), and the Model AA, or "Baby Maxwell."

Torpedo bodies are much in evidence—the Winton and White and the Studebaker-Garford "Gunboat" coming especially under the observation of the crowds. The White gasolines form a particularly interesting portion of the company's exhibit, with "Billy" Taxis and his brother Ed among the "con" artists who hold forth at the sign of the famous steamer. The Winton exhibit—all sizes, of course—is one of the finest under the armory roof, and includes, besides the torpedo body, a touring car, a toy tonneau and a roadster.

The Thomas, Chadwick, Lozier, Peerless-Cadillac, Overland-Marion, Premier, Royal Tourist and Stevens-Duryea exhibits all have four models on exhibition, most of them in addition having



A Glance Down One of the Aisles Shows Neat Arrangement and Plenty of Room for Customers to Inspect the Cars

Some Representative Exhibits That Appealed to the Photographer's Art

a highly polished chassis also displayed. It is rather unfortunate that the exhibitors should have been compelled to do so much crowding in order to set forth even a moderately comprehensive exhibit of their goods. But "needs must when the devil drives," and all hands are doing the best they can under the circumstances.

That the show will result in business has been demonstrated even thus early. Several cars were sold outright to-night, and despite the crowds a vast amount of missionary work was done. Out-of-town agents and subagents are already coming into town, for Philadelphia has become quite a distributing point for a big territory during the past twelvemonth, and concerns like the Studebaker, Ford, Locomobile and Maxwell branches are making big preparations to handle the up-State, New Jersey and nearby Southern visitors when they begin to descend in force.

The Autocar Company, as one of the members of the local Trade Association and entitled to first-week representation, selected the second week to show its pleasure cars, which goes to verify the rumor that that concern proposes to especially push its commercial vehicles during the coming year.

Studebaker Bros. Company have so much to show that they have secured space for both weeks, and will be represented in the pleasure class during the entire show, in addition to a comprehensive display of commercial cars in the last half of the exhibition.

The Collings Carriage Company, a newcomer in the local field, will be prominent during the second week with a three-section exhibit—the Rainier in the pleasure class, the Waverley in the electric section and the Crane & Breed in the commercial car section. Other newcomers to the local field who will exhibit during the second week will be the Otto, by the Otto Gas Engine Works; the Springfield, by the Springfield Motor Car Co., and the Empire, by the Motor Supplies Co.

"Home shows" will be all the rage along Gasoline Row during the next two weeks. The "first-weekers" at the show will hold forth at their several Row establishments during the last half of the exhibition; the second-week contingent will have "open-house" throughout the first week. The "rank outsiders"—those who could not get in during the first week and wouldn't take space for the second—will put in a whole fortnight receiving guests at their branch houses and agencies. Among the latter are the Theobald Motor Car Company, Acme; Franklin Motor Car Company, Franklin; J. M. Quinby & Company, Pennsylvania, Simplex and Isotta; Chalmers-Hipple Company, Chalmers-Detroit; Buick Motor Car Company, Buick; Oxford Automobile Company, Gaeth and Brush; Philadelphia Automobile Company, Apperson; Selden Motor Car Company of Pennsylvania; Selden; Palmer & Singer Company, Palmer-Singer; Jackson Motor Car Company, Jackson; Hoopes Motor Company, Crawford and Rambler; Continental Motor Car Company, Speedwell and Parry, and Penn Automobile Company, Paterson "30." These, if combined, could have made a respectable show in themselves, and indicate what the promoters could have done had there been in Philadelphia a building more nearly adequate to the requirements of a first-class show.

KANSAS CITY OPENS FIRST OF TWO SHOWS

Kansas City, Mo., Jan. 18—The first of the two shows scheduled for Kansas City this season opened last night in Convention Hall. An abundance of flowers entered into the scheme of decoration. When the visitors passed through the south entrance the first thing that struck the eye was the double-decked tea garden on the far side of the auditorium, festooned with posies and electric lights. Around the sides the empty balcony seats were screened off with large panels depicting Western scenes, some of them reproductions of the work of the late Frederick Remington. In front of the first terrace of the tea garden is a rock embankment; the second level is a pergola with the trellis green with Southern smilax. A hedge fence of the same plant runs down the center of the hall to separate the exhibits. The show is conducted by the Motor Car Trade Association, with the following committee in charge: W. S. Hathaway, chairman; E. P. Moriarity, Fletcher Cowherd, Jr., C. C. Meade, W. M. McGee, R. H. Collins and J. F. Witwer.

Another View That Caught the Artistic Eye of the Man With the Camera

CHICAGO'S SHOW ATTRACTS NORTHWESTERN LUMBERMEN

CHICAGO, Jan. 17—In view of the extensive purchases of automobiles by backwoodsmen from Alaska, Great Bear Lake, Saskatchewan and contiguous parts, the management of the Chicago show has decided that special care should be taken to make the Coliseum and the Armory seem homelike to these wanderers from the tall timber. This is the real secret of the setting of forest trees which has been planned for the show. Additional details can now be made public of the arrangements for the entertainment of the Saskatchewanderers.

When the lumberman in search of an auto strides into the Coliseum entrance, his nostrils will be greeted by an aromatic odor which will recall to his mind the tall pines of his homeland. Under this magic influence each visitor from the Northwest is expected to buy at least three touring cars and a limousine. The perfumery used was tested in one of Robert Edeson's Hudson Bay dramas, and one man in the audience was so affected that he tried to chop down a balcony column with his penknife. He was not a Presidential candidate.

Realizing that visitors from the fashionable North Side, whose only knowledge of the timber lands has been gleaned from Stewart Edward White's novels, may not be sufficiently inured to this strenuous influence, Manager Samuel A. Miles has provided a counter attraction in the Annex. Here the decorations will recall an old-fashioned rose garden. Fountains scattered among the chassis and the landaulets will spray rosewater, burdening the air with a sensuous perfume. No taint of brass or lubricating oil will jar the perfect harmony.

Still another class of visitors will be made to feel especially at home at the Armory, which, Manager Miles says, will be provided with a "rustic atmosphere." So far not a whiff of this has leaked out, and the scribes on Automobile Row can but speculate as to what product of the barnyard will be used to give the effect. Something startling is expected.

However, atmosphere alone will not be depended upon to produce the impression of varied settings. A number of real trees are to be imported for use in the Coliseum forest; the specifications call for eight trees sixty feet high, fifty feet spread and two feet in trunk diameter, and four trees twenty feet high, ten feet spread and one foot trunk diameter. These are to be brought from Wilmette in due season and disposed artistically around the floor. The exhibitors' spaces will be marked off with brick walls and iron fences, and the aisles will be lined with bay trees. The trees will also be surrounded by fences, and it will be strictly prohibited to carve hearts and initials on them.

The Annex will be fitted up with trellis-work and wire netting interwoven with foliage, and bay trees will be scattered around in great numbers. In the center of the Armory will be four pagodas, and divisions will be made by rustic fences with ornamental corner posts surmounted by vases and foliage.

"This will all cost money, and will involve a larger expenditure than ever before for decorations and atmosphere," says Manager Miles. "However, it is my ambition to give Chicago an exhibition and a setting that will rival anything ever offered. My estimates call for an outlay of over $75,000 in decorations alone."

NATIONAL CAPITAL SHOW BEGINS SOON

WASHINGTON, D. C., Jan. 17—From present indications the automobile and aeronautical show to be given in Convention Hall during the week beginning January 24 will be the biggest trade display ever held in this city. Nearly every inch of space has been taken, and Manager B. R. Johnson is endeavoring to squeeze in a number of belated exhibitors.

A big feature of the show will be the display of aeroplanes and fittings, which will be under the direction of H. Chadwick Hunter. He has been very successful in securing exhibits for this department, and among them are several machines unfamiliar to the Washington public. The Warner Instrument Company will exhibit a Curtiss biplane equipped with a Warner anemometer. The Berliner monoplane, now nearing completion, will be given its initial tryout before the show opens. The Ormer, Smidley, Christmas and Smith aeroplanes, all local productions, will also be shown. The Government is to loan the committee a number of war balloons and kites, and there will also be a comprehensive display of engines and parts.

W. C. Long, chairman, has selected the following dealers as members of the show committee: John S. Larcombe, Jr., secretary; John R. Thomas, treasurer; C. W. Bender, William Jose, S. A. Luttrell, R. C. Wilson, A. G. Carter, C. E. Miller and L. D. Moore, Jr.

INDIANAPOLIS WANTS A NATIONAL SHOW

INDIANAPOLIS, Jan. 17—A plan for a national automobile show to be held in this city next fall has been launched by Carl G. Fisher, president of the Indianapolis Motor Speedway Company. He suggests that the New York and Chicago shows be reduced to the rank of local affairs, leaving the Indianapolis exhibition the only national one. He further suggests that the show be held on the Speedway, with the exhibits under tents, and the use of the course free to all participants. The Indianapolis manufacturers and the promoters of the Speedway naturally like the idea, but it is doubtful if it will find much favor elsewhere.

SPACE ALLOTMENTS FOR BALTIMORE SHOW

BALTIMORE, Jan. 17—The task of awarding the spaces for the second annual automobile show under the auspices of the Automobile Club of America at the Fifth Regiment Armory, February 22 to 26, has been completed. Thomas Young, chairman of the publicity committee, announces the following exhibitors:

Dixon C. Walker Auto Company, E-M-F, Flanders and Studebaker cars; Lambert Auto Company, Maxwell; E. L. Leinbach, Matheson; "Little Joe" Weisenfeld, Oakland and Reo; Motor Car Company, Stevens-Duryea; Boyd-Eastman Company, Apperson; F. W. Sandruck, Gaeth; Ford Auto Company, Ford; Palace Motor Car Company, Kline Kar; White Automobile Company, White, Neely and Ensor, Alco; Griffin Garage, Knox; Viola Oil Company, M. Denton, Bowser tanks; Mar-Del Mobile Company, Packard and Franklin; Shaffer Motor Car Company, Pullman; Standard Oil Company, Mount Vernon Motor Car Company, Autocar; Zell Motor Car Company, Hudson, Peerless, and Chalmers-Detroit; Auto Outing Company, Palmer-Singer, Haynes and Buick; Walter Scott, Crawford; Baltimore Buggy Top Company, J. G. B. Davy & Company, accessories; Auto Supply Company, accessories; Winton Motor Carriage Company, Winton; General Auto Company, Parry; Fose-Hughes Company, Pierce-Arrow; Standard Motor Car Company, Cadillac and Oldsmobile; Charles S. Houghton, Overland.

FURNITURE CITY WILL HAVE A SHOW

GRAND RAPIDS, Mich., Jan. 17—After trying in vain for several years to develop enough interest, this city has finally decided to have an automobile show, to be held February 17, 18 and 19. Twenty thousand feet of floor space will be provided in one of the big furniture exhibition buildings, and fifty-six exhibitors have already engaged space. Being held just after the Chicago and Detroit shows, it is believed the local exhibition will attract many of their features. Grand Rapids is the center of a large territory of automobile users. A. H. Vandenburg is chairman of the committee in charge of the show.

BUFFALO WILL HAVE MOTORBOAT SHOW

BUFFALO, N. Y., Jan. 17—The Third Annual Power Boat and Sportsmen's Show will be held here March 21 to 30 in Convention Hall. The decorations contemplate the conversion of the entire hall into a Japanese garden. D. H. Lewis is the manager.

Fig. 1—Everitt "thirty" touring car, presenting a long wheelbase, large diameter wheels, roomy tonneau, and a sense of comfort

ADVANCE is made in the art just as designers forge ahead in the work under their direction, and evolutionary methods govern. True, automobile designing has its many angles, but when the situation is fittingly canvassed there are but few schools of design, and deviations in point of detail within schools does not result in types. When a new school of design is instituted, and it has had time to prove its ability to breast the waves, it is fitting to discuss its details and note its advantages.

The Everitt automobile, made by the Metzger Motor Car Company, Detroit, Michigan, is readily separated out into a type, particularly if the motor is examined, nor does it take more than half an eye to note the reason for the distinction. The general appearance of the Everitt automobile will be apparent by noting the title illustration, which is reduced from a photograph of the car. The particular mechanical construction which greets the eye of the keen observer, and which differs very materially from other schools of design, lies in the motor.

CYLINDERS AND UPPER HALF AS A UNIT

The motor, which is given a 30-horsepower rating by the company, has four cylinders, 4 x 4 3-4 inches bore and stroke, respectively, and according to the rating the power delivered is 4.4 horsepower more than the A. L. A. M. rating, which is 25.6 horsepower. Referring to Fig. 2, the four cylinders C1 are en bloc and integral with the upper half of the case C2. It is this part of the design which gives to the Everitt its class distinction, but there are other features to be noted, which in a considerable measure must account for the fine performance of the power plant.

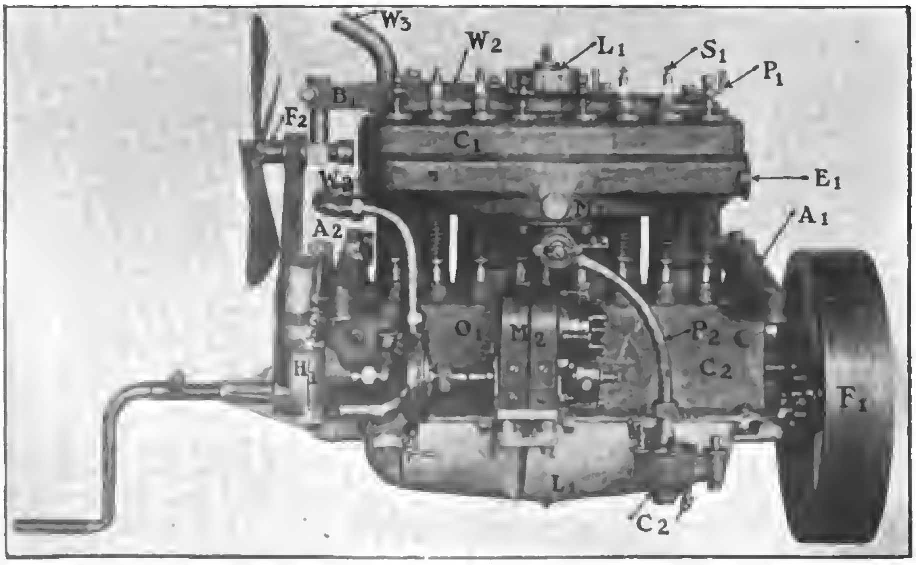


Fig. 2—Power plant, showing a distinct type of motor with cylinders and case integral, and accessories in convenient relation

There is a great difference between atomized liquid gasoline and a vapor of the same; vapor is formed during a change in the state of aggregation of the liquid (from liquid to vapor), and during this change heat units must be added to the liquid—it must be raised to its boiling point and enough energy must be taken up by it to equal the latent heat of evaporation. In this motor, rather than detract from the power by having the liquid (in the atomized state) changed to a vapor in the combustion chamber, the construction is such that exhaust products of combustion are utilized for the purpose, and the gain is a double one; exhaust heat is recovered and the energy cost of vaporization is not at the expense of the ability of the mixture as it enters the cylinders.

This considerable advantage, it is claimed, is brought about in the matter as follows: The intake M1 is cast integral with the cylinders, and the exhaust transfer ports, being also in integral relation with an opening, E1, have but a separating wall between the intake and the exhaust for a considerable distance, enables the heat units in the exhaust to transfer to the mixture in the intake, with the result that the atomized liquid gasoline is changed to a true vapor before it enters the cylinders at all.

There is still another gain, so it is said, in this performance; if liquid gasoline is allowed to enter the combustion chamber, the action will be that of a coke oven, and carbon will coke out, thus forming a carbon crust over the surfaces of the cylinders, and, as is now well appreciated, this crust will act as a shield, preventing the cooling water in the jacket from performing its function, and preignition will ultimately be the phenomenon that the unlucky autoist will have to cope with.

By vaporizing the gasoline before it is allowed to enter the combustion chamber, then, the following gains may be noted on the right side of the ledger:

(A) Heat will not have to be applied to the gasoline after it enters the cylinders to vaporize it.

(B) Coking out will be aborted.

(C) Homogeneousness of the mixture will be assured.

(D) Combustion will be more complete.

(E) The mean effective pressure will be higher.

(F) Heat will be recovered from the exhaust and turned to good account.

(G) The power delivered will be on a higher level.

There are other considerations to be given due weight; homogeneousness of the mixture is the dream of the pure theorist; it is extremely difficult to realize, and yet this quality is absolutely essential if a motor is to deliver power in proportion to speed. It is one thing to design a motor which will have a certain maximum power rating, but it is quite another point to so design a motor which it will deliver power in proportion to speed over a wide range of action.

If the power does not hold out as the speed changes, "stalling" will be easy, simply because the power will not be available in proportion under changing conditions of speed of the car on the road. It is the road performance of the automobile that is of the greatest importance, and Chief Engineer Kelley of the Metzger Motor Car Company holds to the idea that this is the point of moment. These features of motor design, then, rather than as differences to be used as mere talking points, or to lower the cost of construction, are for the express purpose of increasing the power, to begin with, but, what is more to the point, to make the motor characteristic conform to the chassis requirement on the road under a wide variety of conditions.

As an indication of the furtherance of this prime idea, the flywheel F1 of the motor is designed to afford the greatest possible flywheel effect, with the understanding that this facility enables the designer to work a more capable compression, which is especially advantageous at high speed, and the increased flywheel effect makes it practicable to run the motor at very low speeds under the better conditions of compression which are desired for efficient high-speed performance.

The carbureter C2 is placed low enough to allow of a gravity feed, which makes for simplicity and assured action, but there is still another point in this design which should not be overlooked. The pipe P2, which connects the carbureter with the transfer port in the cylinder casting, is relatively small, it being the purpose to prevent popping back. It is desired to thus prevent this popping back when the valves are timed for the best result, as when both the inlet and exhaust valves are open at one time (overlapped) for a part of the stroke. Popping back will not transpire under the conditions here imposed, for the simple reason that the pipe is so regulated as to its area that the speed of the mixture on its way to the cylinders is higher than the speed of flame propagation in the molecular structure of the mixture.

ACCESSORIES TO THE MOTOR WELL PLACED

The magneto M2 is flexibly mounted, an Oldham joint, O1, being placed between it and the pump shaft. This makes it possible to remove and inspect the magneto, even on the road, and to replace the same with no chance of trouble of any sort. The pump, W1, for circulating the cooling water is of the centrifugal type, is located just back of the housing for the half-time gears, and is driven by a pinion which is inclosed in the housing H1, which meshes with a gear in the half-time system. This pump is packed at both ends of the protruding shaft, and is fastened down to a bracket which extends out from the crankcase.

The timer, for use with the coil and battery system of auxiliary ignition, is so situated as to be readily accessible, and the spark-plugs, S1, are over the inlet valves of the motor, this from experience proving to be the best place. The fan F2 in front is adjustably placed, and the arm B1 is an extension of the water cover W2, which passes over the four cylinders, from which the water pipe W3 passes up and joins with the radiator in front.

The supporting arms, A1 and A2, are forged and separately mounted; they are held in place by security bolts of undoubted competence, and the plan is one that has been accepted by designers of recognized ability as advantageous in many ways. The starting crank is capable, and the end-bearing of the same is supported by a housing which extends out from the crankcase.

UNIT SYSTEM OF DESIGN IN EVIDENCE

Fig. 3 of the live rear axle shows the transmission system connected thereto, and, considering the power plant (Fig. 2) as making up the remaining portion of the mechanical equipment, it is self-evident that the car is composed of the least number of units possible to employ, and that they are so related to each other that there is entire accord between them, brought about by the proper utilization of universal joints.

The torsion tube T1 engages at its upper end with a yoke, Y1, which links to a cross-member of the chassis frame through a suitable mate, and the diagonal loading of the live rear axle is

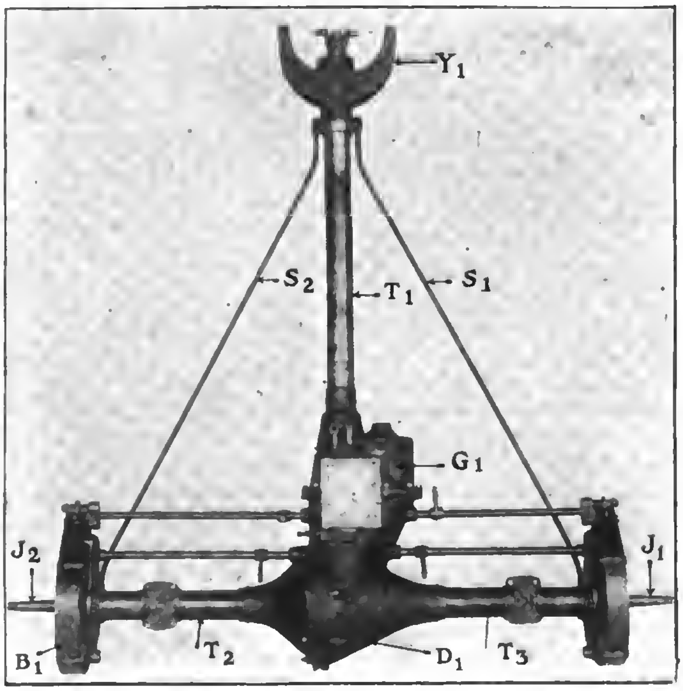

Fig. 3—Live rear axle, with integral transmission, diagonal stays, and torsion tube with universal attachment

cared for by the diagonal stays S1 and T2, so that the tubes of the live rear axle, T2 and T3, are not required to take more than the responsibility which is normal to an axle.

The transmission G1 is compact, does not pick up the ground when the going is bad, and the three speeds ahead and reverse are selective. The brake-control members, as shown, are straight and efficient, and the brakes B1, on steel drums, are efficient and adequate for every possible need, the emergency set being especially designed to take the work if the occasion demands.

The axle tubes, T2 and T3, are of good diameter, made of drawn steel tubing of selected grades, and the differential shafts, J1 and J2, are of specification steel, with a taper-fit for the wheels. This fit has the virtue of holding under all conditions of service, and if it is necessary to remove and replace the wheels, it is possible to do so without destroying the good relation which obtains from the start.

The price of this automobile is $1,350 ready for touring; wheelbase is 110 inches, and the tire equipment is 34 x 3 1-2 inches front and rear. The weight is 2,200 pounds, which, considering the tire equipment used, is a good sign of excellence of road performance at a low cost of tire upkeep. Lubrication is by splash, and grease cups are placed at all necessary points so that long life, as it is dictated by proper lubrication, is assured. Fits of the parts are carefully looked to and noise is aborted.

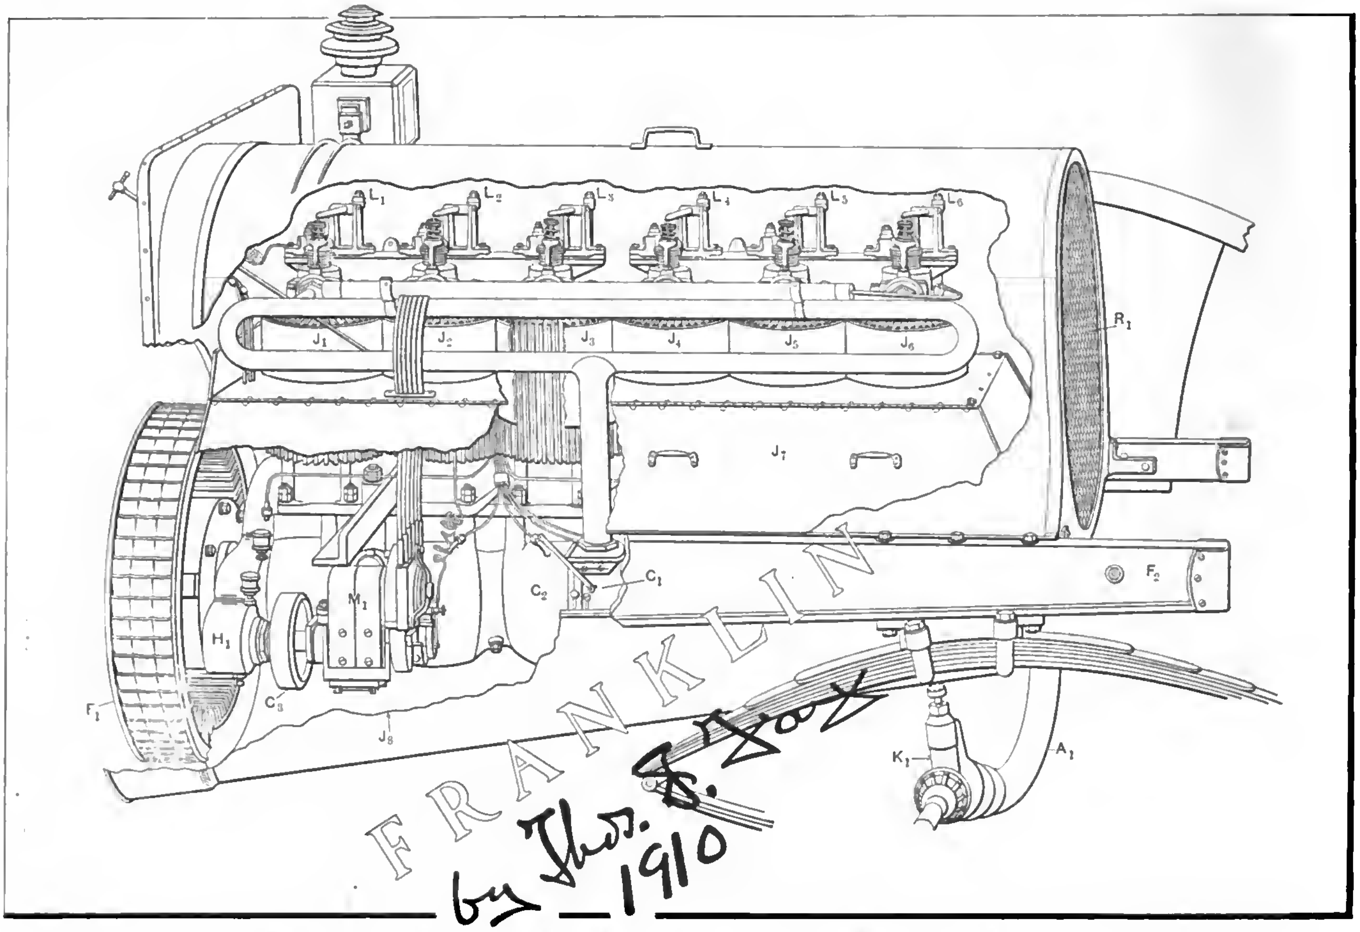

Fig. 1—Franklin power plant for a "six" presenting the latest in air cooling and methods involved in the execution

STRIDES are being made in all directions so far as automobiles are concerned, hence it will come as no surprise when it is stated that the new Franklin (which is the persistent exponent of air-cooling) is much different from the makes from the same company in former years. In the present Franklin power plant, while air is relied upon to accomplish the cooling, the difference shown is by way of a better means of accomplishing the purpose, according to the maker. Instead of relying upon the cooling effect of air drawn over the motor as a whole, with the chances of lack of equality of distribution, the air is transferred, positively, through ducts, and the ribbing on the cylinders of motor, instead of being horizontally around the girth, are in the vertical plane. In this way, since the air is forced to wipe over all the surfaces, each molecule of air is ladened with all the heat it can take away, and each cylinder is cooled exactly the same as the other.

ASSEMBLY OF FRANKLIN AIR-COOLED MOTOR

With a view to delineating the working of the new Franklin system of air-cooling, Fig. 1 is offered, in which the valve motion is the same as formerly obtained, it controlling the Franklin type of concentric valves, and in this assembly the lifts are indicated in their correct relation as L1, L2, L3, L4, L5 and L6. Cooling, in this model, is by means of a current of air which is drawn in through the circular radiator front, R1, by the fan F1, on the periphery of the flywheel, and in view of the proper disposition of air conduits, J7 and J8, the amount of air which passes down around the exterior surfaces of the respective cylinders is fixed by the jacket housings J1, J2, J3, J4, J5 and J6.

The motor case, C2, is of the same shape as formerly obtained on Franklin motors, and the magneto M1 is shown on the right side, driven by means of a shaft with a coupling, C3, lying between it and the housing, H1, for the half-time gears, and a gear for driving the magneto meshes with a gear in the half-time train.

The chassis frame, F2, is of wood, laminated, as in former times, and full elliptic springs are used to take the work, while the front axle A1, as shown, is tubular, and the knuckle K1 conforms to the usual Franklin practice.

AIR-COOLING BY THIS METHOD IS DIRECT

In order to more fully appreciate the directness of the method of cooling used in the Franklin, it will be to advantage to examine Fig. 2, in which (A) is the motor in section at right angles to the crankshaft, and (B) is an end view looking at the front of the motor. Referring to (A) the carbureter C1, is connected to the cylinder by the intake manifold I1, and the concentric valves, V1, are clearly shown in this section. The camshaft, C2, shows one of the cams, and the lift, L1, is of the design using a mushroom. In this section the lift shows the control of the auxiliary valve, V2, of the exhaust, which opens when the piston, P1, is nearing the bottom dwell point, and remains open until the piston ascends for a part of the up-stroke. It is claimed that this auxiliary valve serves as the outlet for over 70 per cent. of the spent products of combustion, and this, as a means of cooling, should not be lost sight of.

Considering (B) Fib. 2, the manner in which the air jacket, J1 (there being one for each cylinder), is fitted around the cylinder, is clearly depicted, and the air-box, the top plate P2, shows the upper line of the exhausting chamber, while the vertical ribs R show in the view, they being very thin, closely spaced around the cylinders and of sufficient area to accomplish the desired end.

GENERAL ASSEMBLY OF CHASSIS AND POWER PLANT

How the chassis, as a whole, appears, is best appreciated by referring to Fig. 3 with the hood off, this being the 4-cylinder model, which differs from the six only in point of the number of cylinders used and such other changes as this situation indicates. The motor, M1, has its cylinders projecting up above the air-box, B2, and, as the illustration depicts, the location of the motor is strictly in conformity with the most modern practice. The transmission, T1, is on the center line and connects with the live rear axle, A1, by the propeller shaft, P1, with a universal joint, U1, at its front end and a similar joint, U2, at the entrance of the housing, H1, of the live rear axle.

The brakes on the rear wheels are of great competence and the control is worked out in a manner to be commended, with the brake shaft, B1, far enough in front of the rear axle so that vertical motion of the frame does not interfere with the action of the brakes whether the tonneau is loaded or empty.

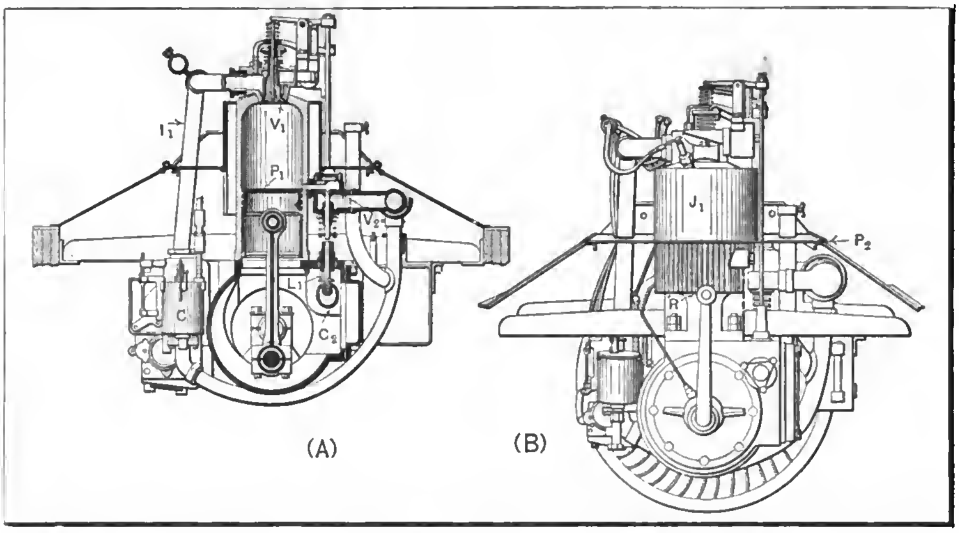

Fig. 2—Sections of the motor; (A) Through a cylinder, presenting details, and (B) Exterior of a cylinder showing method of cooling

Among the other features of the car are nice steering details, the crossrod, C1, being straight, and to the rear of the axle, thus guarding it from damage when the car is in heavy going, as on a soft road, or if an obstruction projects up far enough to strike the axle.

EXCELLENCE OF FRANKLIN FINISH AND BODY WORK

The general finish of the several models is on a high plane, and, in keeping with the trend, a torpedo type, with a Renault front, seems to take the place as the "leader," judging from the attitude of the spectators who hovered around the Franklin exhibit at the late Garden show. The company offers for this year the models as follows:

Model G, as a touring car or a runabout.

Model D, in touring car, runabout, landaulet, limousine, and in a close-couple design.

Model H, touring car, runabout, limousine, and close-couple.

Model K-4, town car.

Model K-3, taxicab.

ATTENTION TO DETAILS TAKES ON IMPORTANCE

Experienced autoists fully realize that, a car may be of excellent design, well made from suitable materials, and still be too troublesome to tolerate. If the wiring for the ignition system, for illustration, is not well installed, ignition troubles (even if the magneto is thoroughly good) will be continuous. In this and the many other ways, involving details, Franklin automobiles have been brought up to a high state of perfection, thus enabling the maker to concentrate upon the air-cooling work in order to bring it up to date as well—this task is finished.

FULL ELLIPTIC SPRINGS USED THROUGHOUT

Much of the fine performance is attributed to the excellence of the spring action; all types of Franklin cars having full elliptics, and, in order to get all there is in this phase of the designing problem, the springs are swung in such manner as to bring out the good working qualities of the materials used. In addition to the springs, there is the wood chassis frame, it being of laminated wood, of suitable design, assures strength even in excess of all reasonable demands, and, as is well appreciated, this type of material is extremely resilient, adds to "soft" riding, and is long of life.

The general appearance of the new models, from the point of view of the springs and frame, is as in former years, but the new front, designed to render the present method of cooling, adds something to the appearance which pleases beyond words. The style is smart, speed is written all over it, and critics seem to take kindly to the idea.

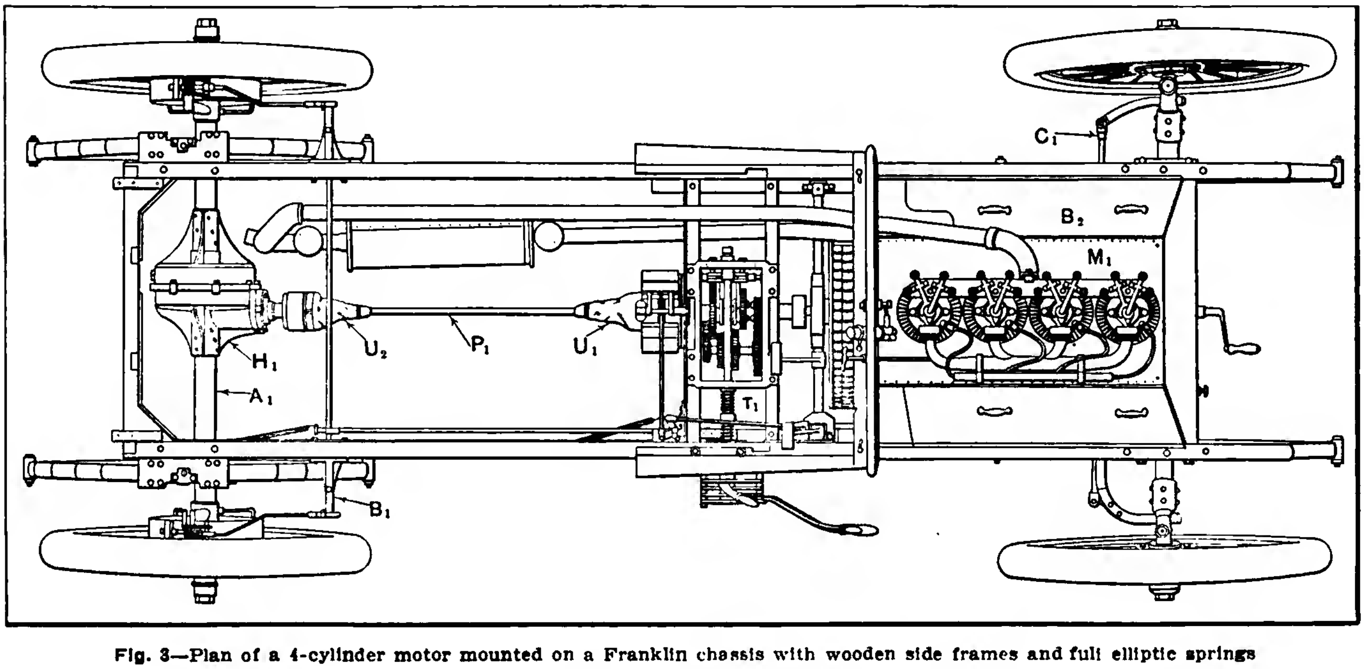

Fig. 3—Plan of a 4-cylinder motor mounted on a Franklin chassis with wooden side frames and full elliptic springs

Some Novelties Presented at the Shows

Fig. 1—Alco showing starting crank so contrived as to eliminate back-kicks under all conditions

THIS year, taking it as a whole, the displays at the shows in New York City partook of novelty along somewhat more mature lines than on former occasions. There was a distinct absence of the little "Yankee notions" of the catch-penny order, but, instead, the keen autoist, looking for something to help out, or influence for economy of operation, would not have to travel far in quest of the device.

The most striking example of budding novelty on a basis of high utility, was in the shape of the electrical generators designed for lighting, in which the speed of the generator is regulated even though the automobile motor used in driving may change speed over broad ranges. Gray & Davis, in the lamp division, presented one phase of this idea at both shows. The Apple Electric Company offered its system in refined form, and Ward Leonard Electric Company is out with still another version of this plan, using a dynamo.

Fig. 2—Example of Packard Landaulet, showing the top folded, wide side entrance and luxurious upholstery

ELECTRIC STORAGE BATTERIES

For lighting work the makers of storage batteries have in hand a class of equipment which is an advance on all former efforts in battery work. For lighting it is recognized that the service is difficult, and the present aim is to prolong the life of the battery rather than to skimp on the weight. The Electric Storage Battery Company, colaborating with Gray & Davis, in connection with its new lighting system, instead of trying to deliver a battery of high weight efficiency, employed the opposite method, and, with the added weight comes an assurance that, despite of the rather severe service, the battery will serve for at least three years under the conditions of operation stated. All along the line, considering the several makes of battery, this general plan of lengthened life is the paramount idea.

HESS-BRIGHT TESTING MACHINES SHOWN

In bearing work there is much to be learned, and, at the booth of the Hess-Bright Manufacturing Company, the question of testing was on the surface. One of the testing machines exhibited was on the principle of the Schlaroscope, in which a hammer falls for a measured distance and bounces off of the test proof. In the Hess-Bright machine it was a steel ball which was substituted for the little hammer, and it is surprising how much the machine tells about the quality of a ball. An inferior ball is at once discovered, and even balls of different materials will show the difference at once.

Still another testing machine by the same company was devised to determine the difference in friction loss as between plain and anti-friction bearings, in which the bearings are required to sustain under conditions of flywheel effect, friction and speed conditions.

MANGANESE BRONZE FINDS MANY IMPORTANT USES

At the booth of the Wm. Cramp Ship Building & Engine Company there was a wide display of Parsons manganese bronze castings, among which the motor frame for the Woods electric attracted almost as much notice as a front axle. This front axle, which was of the I-section, is most readily made in Parsons manganese bronze, due to the shape, which is looked upon by the patrons of this make of car as quite something out of the ordinary. There were many other Parsons manganese bronze parts there to be seen.

The great advances which are being made in the use of "silent chains" was adequately brought out at the shows, and, as an illustration of the many uses to which they are now put, mention will be made of the camshaft drive in the Jackson "thirty." This motor, it will be remembered, is of the "valves in the head" type, and the camshaft is superimposed. The drive, using a silent chain connection from the crankshaft, is noted for its silence, and, while motorists comment favorably, it is only the "wise" of them who look deep enough into the construction to note that the splendid performance is brought about through the use of a silent chain. This is a characteristic of the Jackson "thirty"; the remaining models are made in the conventional Jackson way, with camshaft superimposed, gear drive and a most careful method of lubricating the bearings.

LOW TENSION WIPE-SPARK SYSTEMS

In the ignition methods, as they were to be seen on the various cars, there were so many examples of high-tension work that the average spectator may have missed some of the sights. Take the Premier exhibit for illustration. It might have been observed that the ignition was by low-tension, wipe-spark methods, in which the mechanism has some novel points, among which, it takes but a moment to remove and replace the system of insulation, which is in the form of porcelain bushings, which are all ground to exact size, and an extra set is provided with each car as a part of the repair kit.

The Locomobile, it will be remembered, is also fitted out with low-tension ignition; this company has ever adhered to this method, believing that the energy in the spark is far greater, and that insulation trouble is eliminated, it being the case that the voltage is approximately 100 instead of 20,000. The Gaeth is also in this class from the ignition point of view.

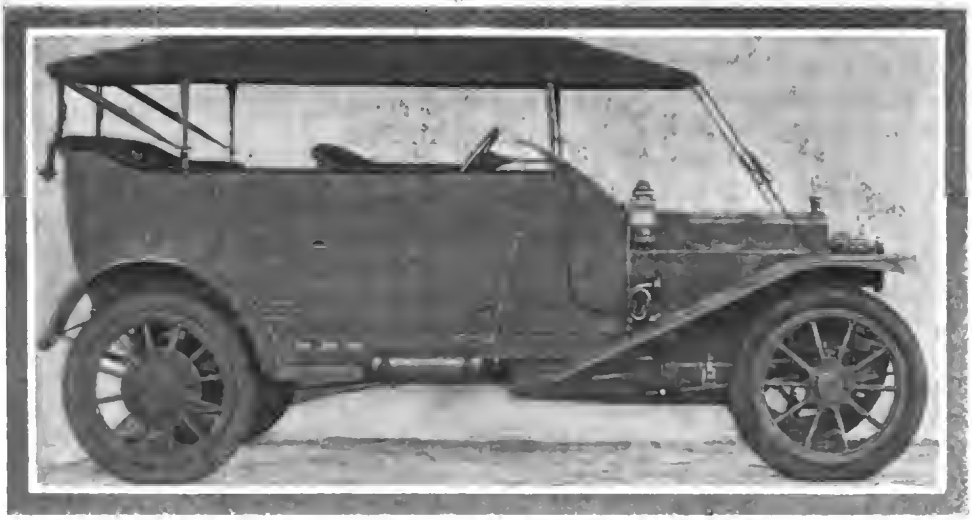

Fig. 3—Marmon torpedo type of body with unusual height of the superstructure.

ALCO COMES OUT WITH A NEW CRANKING SAFETY

The title illustration of this article shows the front of an "Alco," made by the American Locomotive Company, Providence, R. I., and S1 calls attention to the starting crank, which is different from any regular crank which was formerly used on Alco automobiles, although, last year, the company tried out this device, and, as it was at first reported, it was to be put on as a "special" this year.

Added experience with this device was so gratifying that the company decided finally that it should be regular, claiming that, in the furtherance of safety, the device might well be placed at the disposal of every user of Alco automobiles. As is well appreciated, when a powerful motor is being cranked, if the cranker is not careful, he is liable to experience a "back kick," and, according to insurance statistics, there are enough accidents which may be directly traced to this class of trouble to warrant the safeguarding of purchasers of this class of cars.

The crank, as shown, is so contrived that when the car is being cranked, if the operation is not properly performed, nothing of a disagreeable nature will transpire, because the finger which extends out beyond the starting crank will be engaged on a back motion of the crank, and the finger being connected to a reverse motion in the housing of the device, throws the crank out of engagement, positively, and what is equal to the point, within a very short angular travel of the starting crank. This device is very simple, there are but few parts, and they are sturdy.

PACKARD BODY WORK

Fig. 2, which is of a Packard body as it was exhibited at the Garden, is sufficiently distinctive to warrant utilizing it here on the score of a specialty, and, as the figure indicates, it has art written all over it. The foundation of this, like all Packard body work, is by way of well-designed framing of ash, from seasoned wood, which is held in the Packard yard for fully five years before it is brought in and placed in the drying kiln with a view to further and desirable treatment.

The Packard kilns are especially designed for this class of work; means is provided to regulate the heat, and as the vapor rises it is condensed and carried away. The result is that the wood is well kiln dried after it is yard seasoned, and, naturally, under such careful conditions, the wood, before being stored in the yard, is inspected by a "forester."

The ironing, while it is designed to limit weight, is given the same care as an axle or a crankshaft, and the strength of the frame is therefore maximum, although Packard body work, taking it as a whole, ranks as light. The aluminum sheets, as they are attached to the framing, are "butt-jointed," and to cover the points a half-round trim piece is lined up over the joints. In order that the trim will look artistic, the aluminum is so cut that the joints favor the undertaking, and, since all the trim pieces are screwed on after the holes are drilled, the work is securely held, while the finish is perfect, because the screws are all countersunk.

The aluminum, besides being securely placed, is of sufficient thickness to stay in place, and the chances of denting are eliminated, due to backing which is placed wherever the situation would seem to warrant. At one or two points castings are used, they being of aluminum, it being the idea to add to the strength of the framing, and make difficult curves. The finish on the body shown is up to the limit of the carriage-maker's art, and, with the work all done in the Packard plant, under the watchful eye of skilled and exacting inspectors, there is nothing

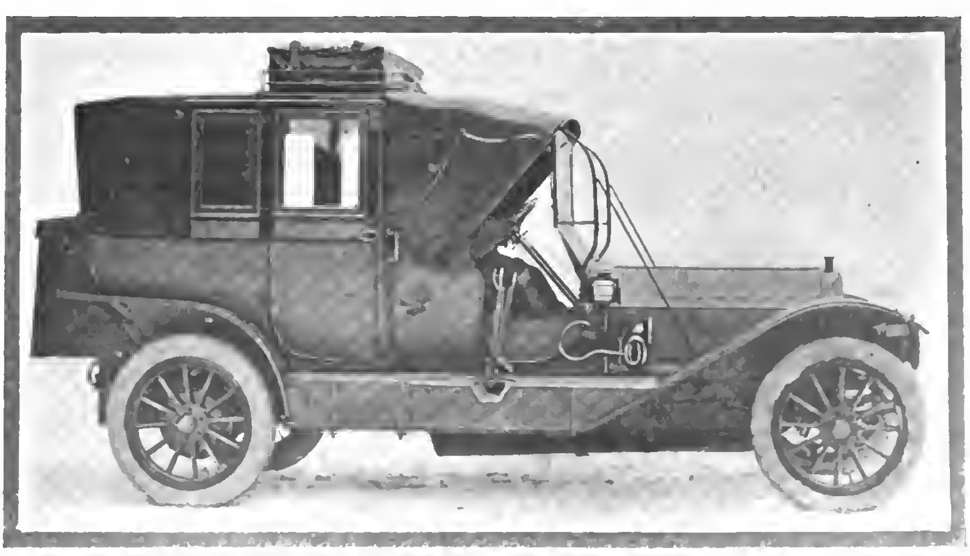

Fig. 4—Pierce-Arrow automobile fitted with a commodious touring body, including comfort.

Fig. 5—Palmer-Singer torpedo type of body, looking in to see the collapsible front seat which facilitates

to expect but the longest possible life from this point of view. First-rate work is the cheapest in the long run.

The entrance is wide, and the upholstery within is that which makes the lap of luxury. Purchasers are given a wide choice of materials for upholstery work, and, according to the usual Packard practice, it is the aim to give to each owner just the results desired, considering, within all seriousness, the artistic tastes of those who indicate capacity to judge.

MARMON COMES OUT WITH A TORPEDO TYPE OF BODY

Of the torpedo types of body work which were seen this year at the two New York shows, it is highly improbable that any of them attracted more attention than the Marmon. This body, besides being of the usual Marmon construction, which stands for stability as well as comfort, affords additional protection, due to the height of the sides, as the illustration, Fig. 3, adequately portrays. The entrances are commodious, interior work is on a basis of luxury without being in bad taste, and the whole situation portrays a considerable advance on the original idea of torpedo body work as it floated across the Atlantic a few months ago. This car has ample room, and seats five.

PIERCE-ARROW PRESENTED A TOURING CAR OF INTEREST

At the Garden there were many sights to whet the interest of the man who sees things, but, taking the situation as it would appeal to the "globe tourer," there was much to be said for the "big" touring car, Fig. 4, quite naturally, in view of its roominess, then, due to the accommodations offered.

Space for baggage, the utensils of a protracted tour, and the "home comforts" which even a hotel limits, may all be found in the Pierce-Arrow. In many places, especially abroad, a day's run is full of little disappointments, and a space for eatables and refreshments is easily possible in this car. The upholstery, while it is artistic, is more so because it is substantial.

LOOKING INTO THE PALMER-SINGER TORPEDO

The new body of this make was most interesting, and is representative of the original torpedo idea, limiting the facilities of ingress and egress to a single door (on each side of the body), so that to take a front seat it is necessary to "collapse" the one beside the driver's, pass to the front and thereafter erect the seat. It is a fine piece of work, and the ingenuity displayed in the construction of the collapsible seat is well worth examining personally. The general appearance of this body is up to the original foreign idea, but, if anything, the character of the workmanship is one better.

DORAIN DEMOUNTABLE RIM FEATURES

Glancing over the rims that came to the surface at the Garden during the show disclosed several new ideas, among which the "Dorain," as here illustrated, Fig. 6 (A) presenting the wheel with the tire inflated on the rim ready to use, and (B) depicts the wheel with its Dorain demountable features.

Referring to (A) of the figure the security bolts B1 and B2 are held in relation to each other by means of the bar or

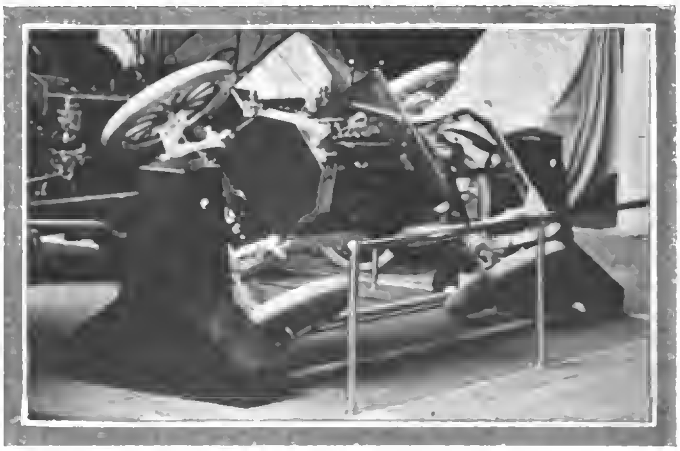

Fig. 7—Novel tilting frame used in the Thomas booth at the Garden to bring out good points of the Thomas chassis

keeper, K1, and since the nuts are designed with an integral flange, which fits under the caps, the whole unit may be removed, layed down, and when it is picked up again the nuts will be in place, being held by the flanges. The felloe of the wheel proper is in no way reduced in section, it being true that the auxiliary rim is plain, just as it would be in a standard clincher, were it necessary to employ one under the rim which holds the tire, as it is in demountable work. B, Fig. 6, shows the same wheel with the tire removed, and the parts which compose the locking device are also exposed to view, in which S1 is a socket wrench, the only tool required to remove and replace a tire, and K is the connecting portion of the keeper, of which four are used on a rim.

The terminations of the keepers are flanged, and the flanges, as shown, are with a wedge shape, W1 and W2, which wedges are forced up between the clincher and the supplementary rim, which is shrunk over the felloe of the wheel to hold the woodwork in secure relation.

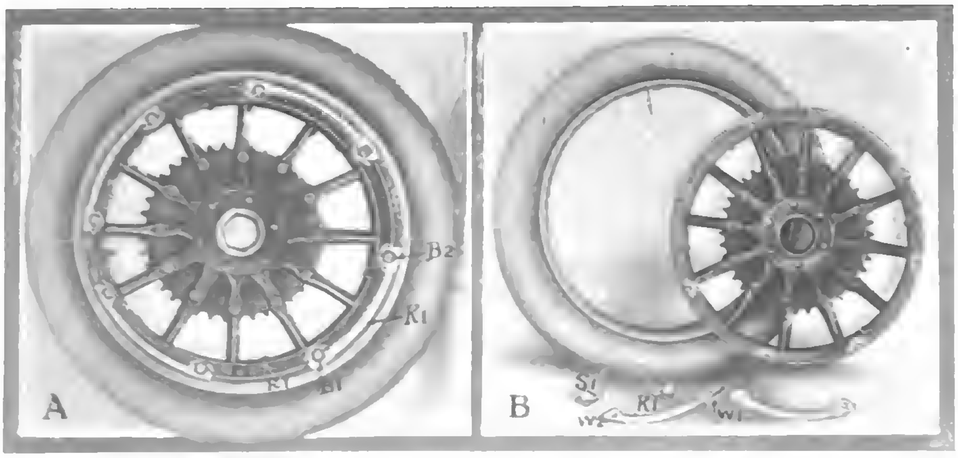

Fig. 6—Dorain type of demountable rim: (A) presents the rim and tire in place; (B) is the rim separated from the tire

STABILITY INDUCED BY EFFICIENT COOLING

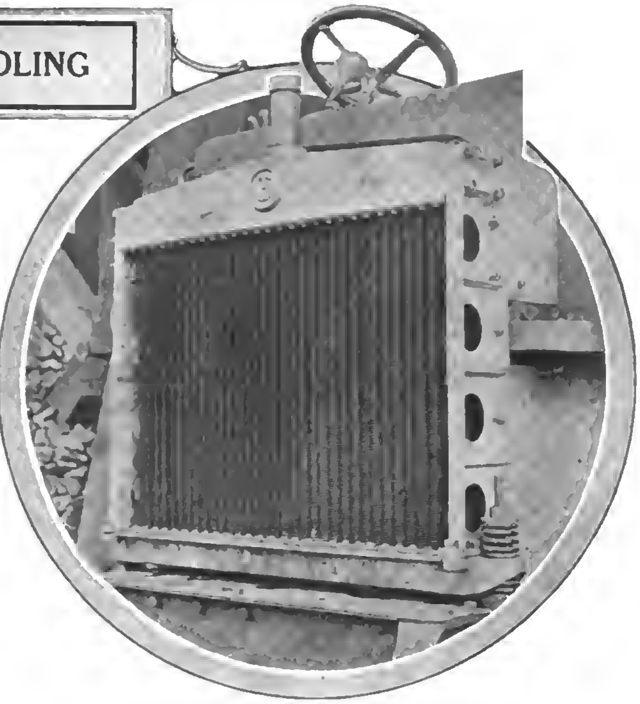

Fig. 1—Alden Sampson truck presenting method of cradling a strong type of radiator to sustain in trucking service

EFFICIENCY has many phases; thermal economy represents one of them, and, as a rule, when the thermal efficiency is at its best, it is nearly sure that the weight efficiency will show up favorably. The service efficiency, on the whole, is scarcely to be measured along the same lines, for, while the thermal efficiency and the power for weight may both be quite high, it is possible to have a condition which may be far from a high service efficiency.

In cooling, if the system is not one to assure stability under the most severe conditions, service efficiency will be at a low ebb. If a radiator heats up when a car is standing at a curb, it will take quite a little coaxing to realize a sufficiency of power for some time thereafter, or if in hill climbing the same heating is induced, it is a sign that service efficiency is too low, no matter what the "block" performance of the motor may be.

By "block" performance is meant the results which may be obtained from a motor on a testing block under the conditions which are likely to obtain if, in the testing room, the man in charge is lacking in "road" experience, or is trying to clear up the "floor." In abuse testing, which involves a run of, say, 100 miles, if the tester is alive to his opportunity, he will be able to tell if the radiator is competent, but if he fails to bring out the strong points, the purchaser will have the pleasant duty of finding how strong they are in fact.

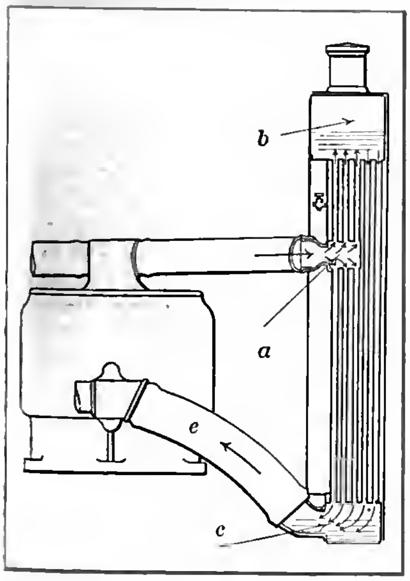

Fig. 2—McCord type of thermo-siphon radiator, as used on Regal automobiles, showing a pocket for the steam to distribute in

RADIATOR DESIGNS

In general practice the problems involved are now quite well understood, and, as a rule, the ratio of flame-swept surface to radiator surface is quite well regulated, whereas, it was not so long ago that builders of motors thought that all essentials were cared for when the maker of the radiator was informed as to the horsepower ration of the motor, nor was there any assurance that even that rating was in full accord with the exact requirement.

In truck work, where the motor is required to operate under rather severe cooling conditions, it is the practice to allow a liberal rating of the radiator, and to introduce rather more of mechanical stability that will be found necessary in pleasure types of automobiles. Fig. 1 portrays something of this condition. The radiator is suspended on a flexible cradle, as it were, it being the idea to eliminate shock to the greatest possible extent, which is accomplished by a flexible mounting.

McCord Manufacturing Company—The radiator as shown in Fig. 2 is of the thermo-siphon type of special construction as used on Regal automobiles, in which a pocket is formed at a point part way down from the top of the radiator and the water with entrained steam enters this pocket where it is separated out, and the water passes up or down depending upon the conditions, but all the water, properly cooled, ultimately passes to the bottom of the radiator and thence back to the waterjackets of the motor cylinders. Fig. 2 (A) is another type of McCord radiator showing a form of rigid fastening, (B) depicts the lap of the McCord vertical tube, which is made on a special machine, and (C) is a "trunnion" type of cradling as used on this make of radiators, which is now quite frequently employed.

Brisco Manufacturing Company—This company manufactures a full line of metal stampings as used in automobile work, and the Brisco types of radiators, of which there are several, are now so common in use as not to require a great amount of explaining. Among the very efficient types used is the vertical tube form, in which plates, placed horizontally and quite closely spaced, serve as the radiating members, and being mechanically

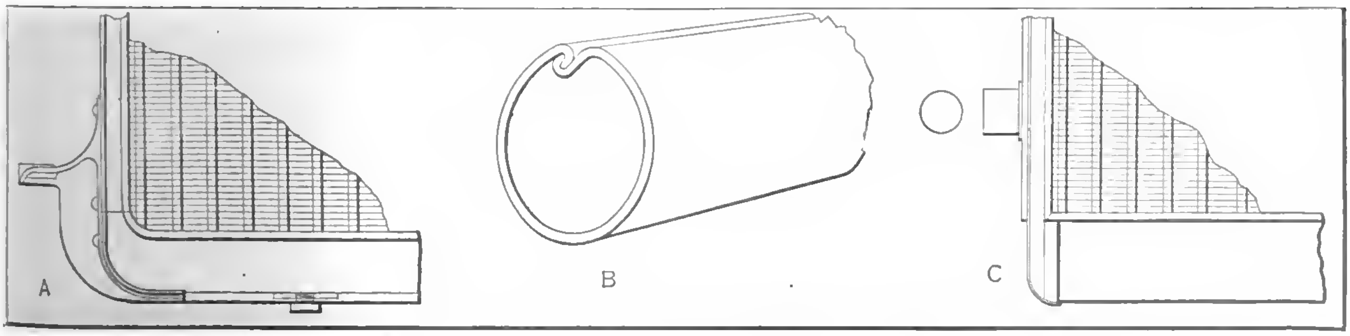

Fig. 3—(A) Fixed radiator support, (B) Tubes of McCord radiator, (C) McCord trunnion support

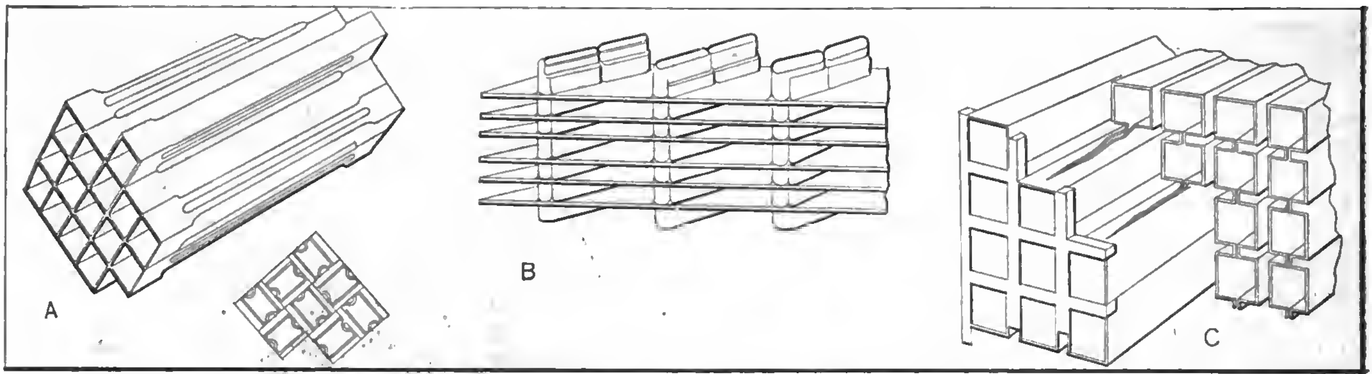

Fig. 4—(A) presents a section of the Brisco honeycomb type, (B) Brisco flattened tube construction, (C) Brisco tubular plan

well spaced with well-finished edges, the appearance is all that can be desired. The honeycomb type, as made in this plant, is much used and special forms are given consideration when it seems desirable to do so.

DATA ON FEDDERS RADIATOR TUBES							
Size of Tubes			No. of Tubes per Ft.	No. of Tubes per Sq. Ft.	Cooling Surface per Tube	Cooling Surface per Sq. Ft. of Tubes	Remarks
A	B	C					
5/16"	1/4"	3⅝"	39	1521	3⅝" Sq. In.	5513 Sq. Inches	15.7% More cooling surface than 3/8" tubes
3/8"	5/16"	3½"	33	1089	4⅜" " "	4764 " "	Cooling surface 86% of 5/16" tubes

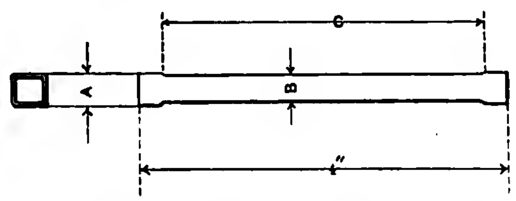

Fig. 5—Dimensions of a Fedders radiator tube as used in the honeycomb type of radiator

Fedders Manufacturing Company—This make of radiator is of the true square tube type, frequently designated as "honeycomb," and in Fig. 5 the dimensions of the tubes are given for one of the sizes made. This class of radiators is used in the most exacting service, especially in high powered motors.

Mayo Radiator Company—Made at New Haven, Conn., the Mayo radiator is now so well known as not to require any introduction at all. It is used on automobiles of excellence and under racing conditions where high duty is one of the important points. This radiator is built up of sheet copper, with every provision to realize the greatest efficiency of radiating surface, and water circulation is looked after with much care.

A-Z Company—In addition to a line of sheet metal work this concern turns out honeycomb and other types of radiators of a class which are used in high-powered automobiles.

W. J. Kells Manufacturing Company—Maker of the well-known Kells circular tube radiators and the true honeycomb type, this company placed before makers this year a line of radiators in keeping with its reputation for efficiency and stability.

Long Manufacturing Company—The Long tubular type of radiator has been so much used that it is too well known to demand more than mention. It may not be generally known in the East at any rate that this is one of the really well-equipped plants in America for turning out radiators of all types and forms. This make of radiator is much used in severe classes of service.

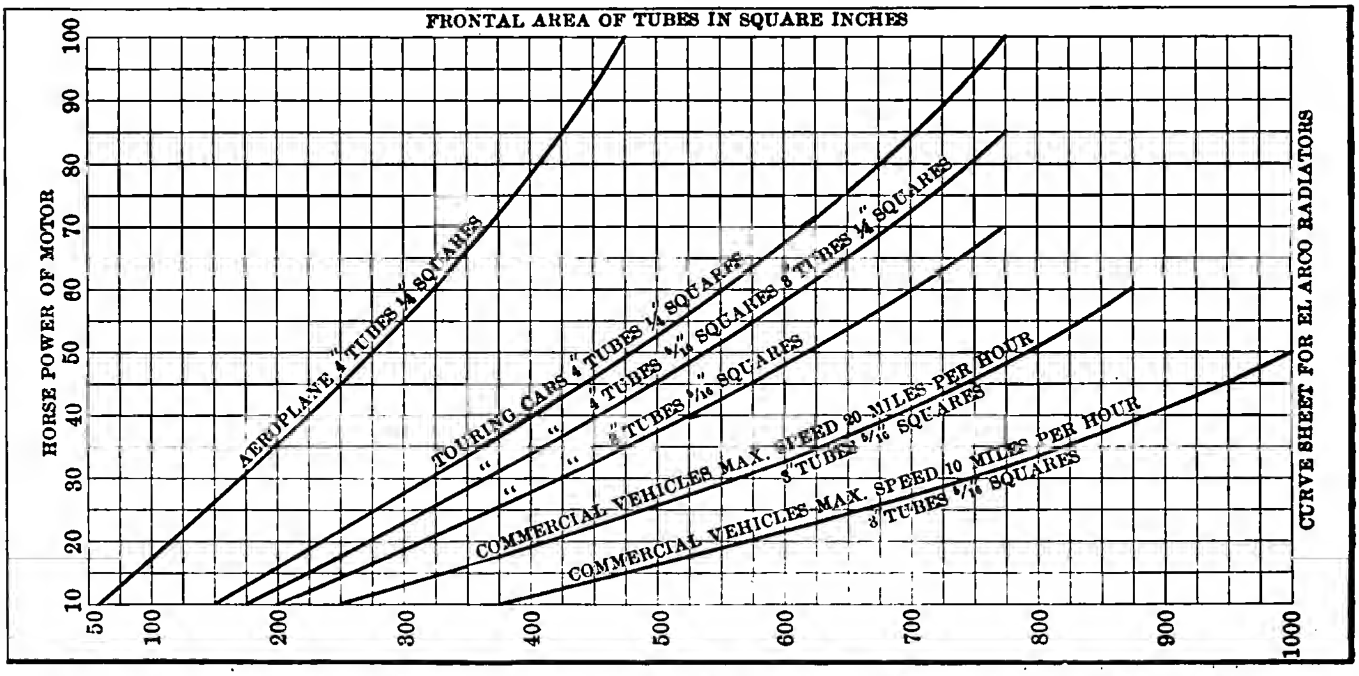

Fig. 6—Curve of horse-power ratings of the Arco (formerly Livingston) types of radiators as used in several classes of service

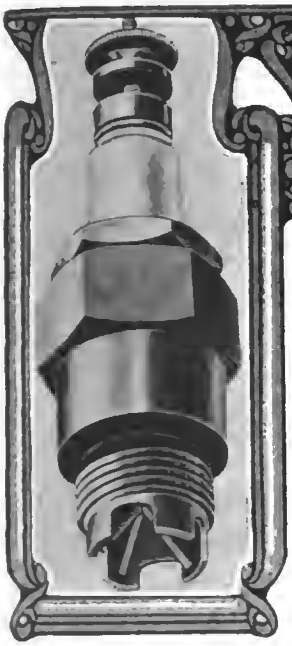
Serviceable Ignition Accessories



U. & H. Magneto Plug

HIGH-TENSION magneto systems deliver, without the aid of a step-up transformer, a sufficient electromotive force to break down the gas gap between the nodes of the spark plugs. Spark plugs disrupt at a voltage slightly above 15,000, hence the electromotive force delivered by the high-tension magnetos must be somewhat less, it being limited by the ability of the spark plugs.

Low-tension magnetos are constructed with but a single armature winding and deliver an electromotive force of about 100 volts, and in conjunction with a wide spark mechanism involving a hammer and anvil in proper relation, the art is drawn at the proper time, thus producing a spark with high energy.

Still another type of magnetos really belongs to the low-tension class in that the armature is wound to deliver a relatively low electromotive force, and a step-up transformer is employed by means of which the voltage is stepped to the higher level sufficient to disrupt the "gas" gap between the nodes of the plugs.

High-tension magnetos are sometimes used in connection with coils, they being sometimes so designed that by throwing a switch the magneto energy is substituted by a battery, and in the design of the magneto a supplementary interrupter is provided, thus accounting for the appellation, dual ignition systems.

Connecticut Telegraph & Electric Company—After two years of experimentation this concern now announces the completion and marketing (after March 1) of a new form of magneto. It will be made in four and six-cylinder types, which will be called 4-A and 6A. In its design, one point particularly aimed at was efficient sparking at very slow speeds, so as to permit ready starting without spinning the armature shaft, and also to allow of running the motor very slowly, which has hitherto been considered an exclusive feature of battery-coil ignition systems.

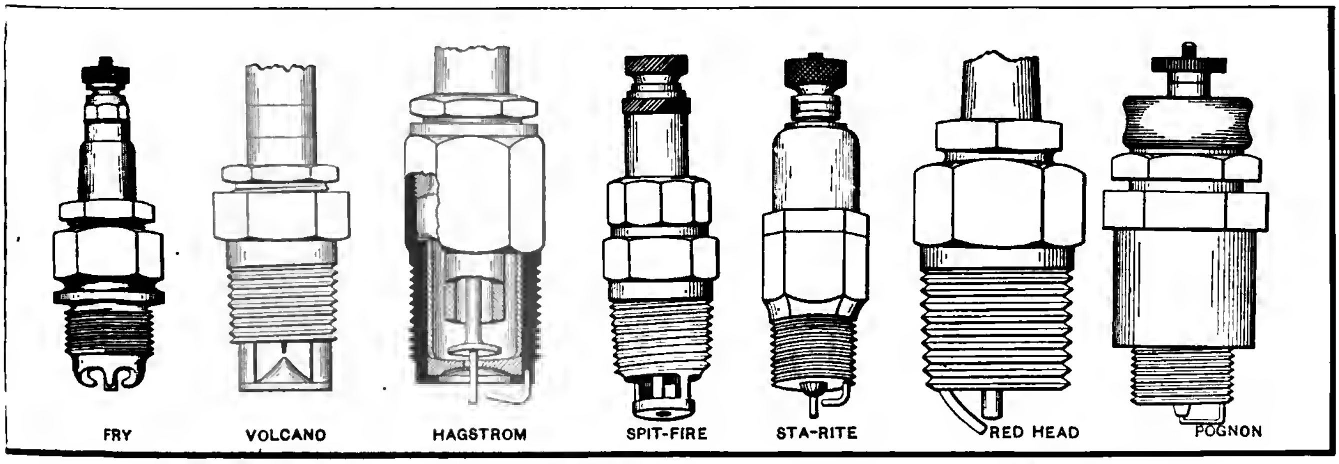
Another feature of merit is the change from right to left hand which can be effected by simply changing three screws. In this way dealers would not have to carry both kinds in stock, while the manufacturer gains also by making all of them just alike. Repair parts too are lessened in number and trouble reduced to a minimum. In place of the usual one spark gap four safety spark gap windows are provided. In case one of the cylinders is missing the spark will immediately jump across these windows, so that the ordinary man not understanding ignition can trace the missing cylinder as well as an expert.

K-W Ignition Company—This firm makes a low-priced magneto and a coil. The former is put out in two styles, one low-tension and the other a high-tension. Both are very simple in construction. Yet the efficiency and serviceability of both is unquestioned. This was well proven by an experience which a Cleveland man had with one of them on a Mitchell car, while touring in the West Indies last summer. On the boat a severe storm broke the car loose from its fastenings and damaged the axle, radiator and other parts located at the forward end of the chassis. When the damaged parts had been straightened and otherwise repaired, the magneto furnished the requisite spark on the first turn and, moreover, continued satisfactorily for some 1,000 miles of touring, which concluded the trip.

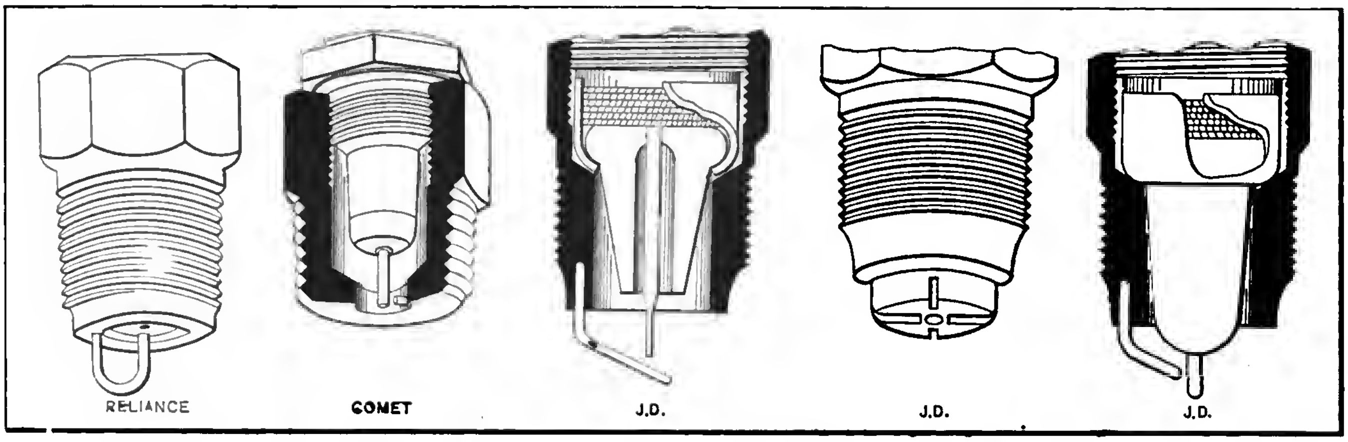
Buffalo Ignition Company—The Volta Magneto is continued for the season of 1910. It is well known as a true high-tension magneto with several valuable features. The whole device is small and compact, the magnets being arranged in pairs with additional pairs within. The contact-breaker box is both simple and accessible, the spring holding the cover on normally being such as to be turned aside by a simple twist of the finger. When so uncovered, the cam is found to have a diamond shape with rounded corners. The breaker is held against the cam, that is the hardened steel roller of it is, by means of a spring coiled around the pivoted end, movement of the arm tending to coil the spring tighter. In this way the tendency is to never lose tension.

Standard Sales Company—In the cut below, the Fry spark plug handled by this firm is shown first. It consists of a brass shell, within which is an all-porcelain center with a metal core, the lower end of which forms one electrode. By removing the binding nut the whole interior part is removable without disturbing anything else. Yet in spite of this accessibility it is sure to be gas tight, as gaskets are used against shoulders.

Volcano Spark Plug Company—This Ashland, O., firm makes a porcelain plug which has a number of important points of difference. The porcelain carries the one electrode as the



Seven Varying Spark Plugs Now On the Market, Showing the Differing Individual Sparking Points



Another Lot of Five American Spark Plugs of Unquestioned Merit, Nearly All of Porcelain

center part of the core, this tapering to a fine point. The other is formed by a cone-shaped projection, which rests on a sort of circular shelf, the latter being connected to the body of the plug by a pair of side columns. The latter being fixed in position, the inside electrode is slightly adjustable up and down to secure the right spark gap distance.

Hagstrom Bros. Mfg. Company—This plug, the third on the previous page, has the unique feature of an internal cavity, which is partially closed at the bottom by a porcelain disc which is forced into the brass shell before assembling. In addition to this the central electrode carries a shoulder just above the porcelain, which in combination with the very small hole through the latter effectually prevents any oil or other foreign materials from entering and short-circuiting the plug.

A. R. Mosler & Company—Among the many spark plugs made by this New York firm the Spit-Fire maintains its popularity. The construction shown, partially in the fourth position on the previous page, is such that the spark must jump or spit through a small hole, thus the derivation of the name. The frame work of the base portion is carried down as a cylinder with two slots on the sides and the central hole just mentioned. The central sparking point projects from the porcelain core down into the very center of this hole.

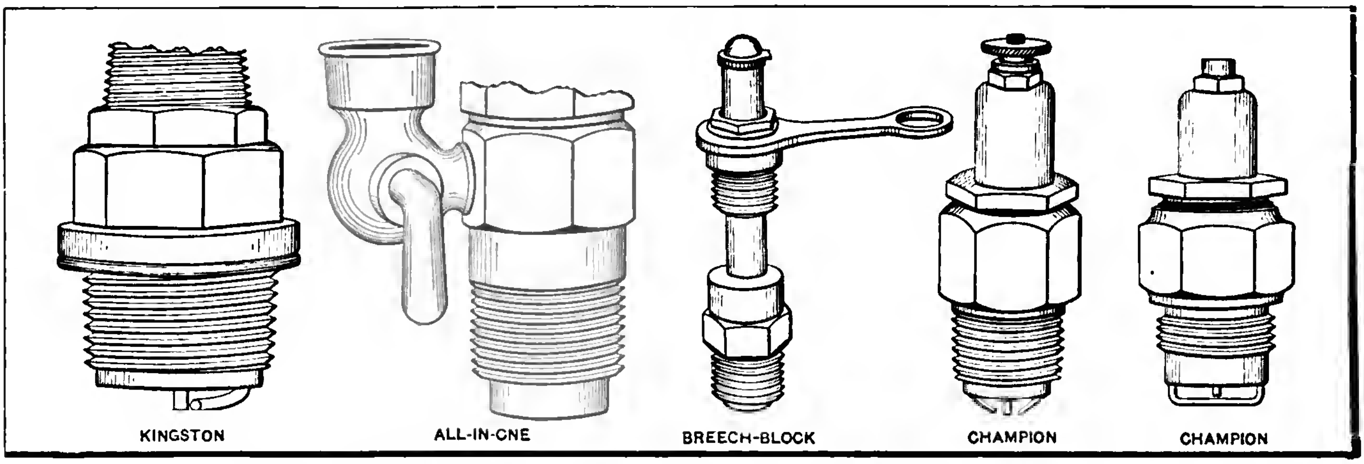
R. E. Hardy Company—At both the Palace and Garden shows, in addition to the well and favorably known Sta-Rite plug, this concern showed a new plug called Apropos. This had a central porcelain with a shoulder, which bore upon the brass shell, while the locking nut jammed down upon its upper surface. The result was a double gasket effect, which insured its being gas tight. The principal feature, however, was the shape of the lower end of the porcelain. The center of this was hollowed out to form a cone, with the sparking point placed in the center of the cone. Oil in the cylinder would, through capillary attraction, draw to the center, in which case it would flow down the sides of the cone and away from the point.

Emil Grossman—Red Head spark plugs, as the cut on the previous page shows, are very simple in construction, consisting of a central core which carries a perfectly straight electrode. This with an inserted platinum wire forms the spark gap, the latter being bent over close to the central point.

Jeffrey-Dewitt Company—Heading the line of plugs made by this Newark, N. J., firm is the Reliance plug. The feature of this is perhaps its ability to spark under water. Since short-circuits are the greatest source of plug trouble, one that will spark continuously under water should be perfectly safe under any less arduous conditions. This firm also makes a lower-priced plug with the same porcelain core, but in three differing styles. The three styles are known as petticoat type, conical type and closed-end type, the name giving some idea of the construction. Thus the first has a form of central porcelain so hollowed out and surrounding the electrode as to resemble a petticoat. The second has a solid conical shape of porcelain within a perfectly vertical hole in the brass, while the third has a closed end, through which four small slots and a central hole allow the spark to fire and ignite the charge.

Oakes & Dow Company—This firm makes the Sootless and Comet, the latter being illustrated above. It has a single central electrode which projects through a large hole in the brass shell. In one side of this latter hole a small platinum tit is set so as to come to within the proper 1-32 in. of the center piece.

Buffalo Carbureter Company—The All-In-One plug serves as more than a simple sparking point, in that it includes a priming cup, which may be used, taken with the pressure within the cylinder, to form a plug cleaning means, while the cup may be used in addition to convey kerosene to the cylinders as well as spark plug, thus cleaning out both. It is a very useful adjunct.



Quick-Detachable Idea and Multiple-Use Feature Appear on Some of the Current Plugs

WIND SHIELDS ARE NOW VERY WIDELY USED

WITH increased use has come increased knowledge of the many advantages of the wind shield, this resulting in a more widespread adoption. This matter has progressed in the past three years, until now it may be said that the present status is such as to include a wind shield among the many accessories looked on as necessary. Or, in the case of this being omitted, the omission is such as to call for its addition as soon as finances will allow.

Comfort, convenience, safety, health, and many more desirable conditions are furthered by the use of a wind shield. Thus, to expand on some of these or to prove their existence, one might take the first, comfort. No one will deny that driving against a head wind is uncomfortable, or against a driving rain or snow, or more, against a dust storm. All these render the driver of the car uncomfortable and uneasy, to say nothing of some of them making the practice of driving dangerous. With a sheet of plate glass stretched across the front of the car, all of them are avoided, as the air, whether laden with rain, snow, dust or other undesirable things, must pass over the driver's head.

In the last analysis, what is a wind shield but a sheet of plate glass, with perhaps a division across the middle or elsewhere, and adjusting means for retaining it in any desired position? This certainly describes the wind shield exactly, and the only difference among the many now placed on the market lies in the materials used, finish given to them, parting of the glass or non-parting arrangement as the case may be, adjustment mechanism and its working.

With the idea, then, of disseminating a wider knowledge of this desirable accessory, a number of its present forms will be described, the cases being taken at random from those exhibited at the Palace and Garden shows, just closed. Space being somewhat limited for such a large subject, the ones illustrated by means of drawings will not be described.

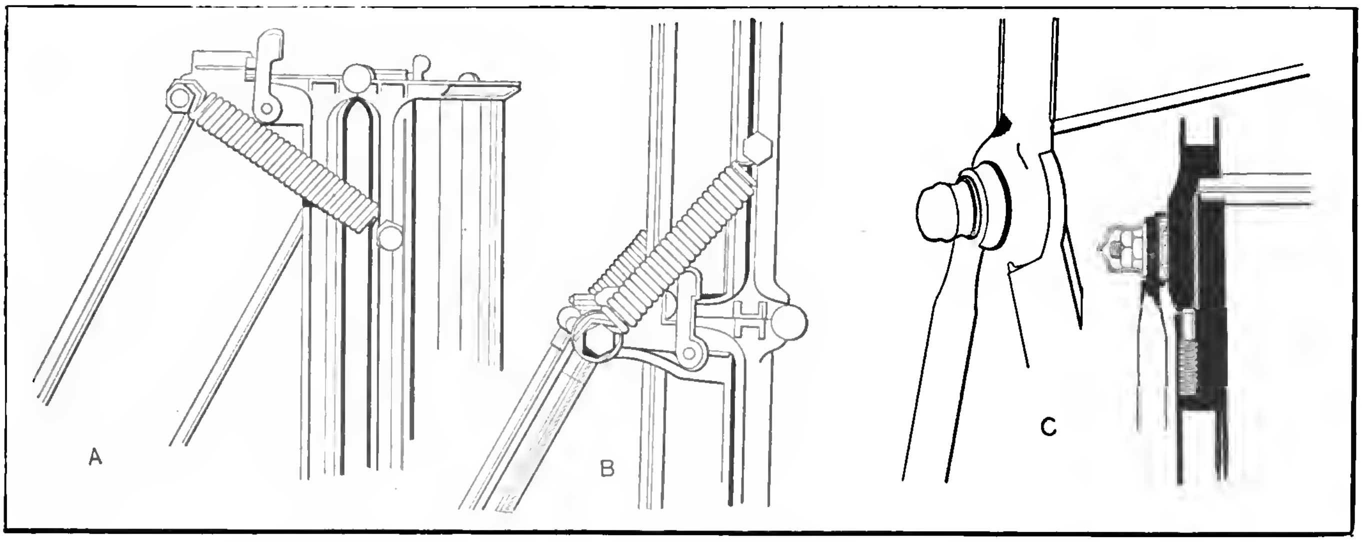
Banker Wind Shield Company—Two styles are made, both of a very high grade of material and workmanship. These are known as No. 1 and No. 2, the difference being small. Of the two, the latter is the one which is being pushed. The principal feature is that of the double fold, which allows of the shield being folded up and laid over the hood when its use is not desirable. Beyond this the glass is parted in the middle, but the parting line is rendered invisible by the absence of any molding or binding along either edge. This does not obstruct the vision as would a metal edge at that same point.

Rubber backing for the glass eliminates any possibility of noise, which, to put it mildly, is not needed. Aside from doing away with noise, this feature is of value, in that it lengthens the life of the whole device. The hinge is always a vital point, and this one has been designed with much care. It is of the so-called piano type, with a knurled locking nut which governs the opening and closing. When it is desired to open the shield so as to lay the top part down, this nut is turned part of a turn, which allows of its being pulled over to the side, and frees it from the knife edges which hold it. When freed, it turns over readily.

Chicago Wind Shield Company—Several named and lettered styles are marketed, among which may be mentioned: Styles R, O C, Dixie, Dixie Tube, Perretz, Telescope, S I, Oriole and Ziz Zag. These differ so widely that it would be impossible to describe all of them, so one or two will be selected for description. The Dixie is an inside folding wind shield, that is, the upper half folds over toward the driver, laying down close to the lower or fixed part when so folded. When folded, it is locked firmly at both top and bottom, so that the objectionable rattle is done away with. This fold is double, that is, the top of the shield has a compound movement about two pivot points, and does not describe a simple circle about the hinge. This is done to clear the steering wheel, which is usually so close to the dash board as to prevent the folding except as described.

Birch is the wood used, while the trimmings are of brass, with corners reinforced by special brass corner plates. The quarter-inch plate glass used is set into felt so as to stop rattling and lengthen the life. There are no thumb screws to take out, and the whole construction is such as to allow of reaching up from a seat at the wheel, folding it up or down, and going on without any fuss or trouble.

English & Mersick Company—This old-established New Haven carriage supply house is placing on the market the Tabor flexible wind shield. This, too, is made with an invisible central line of division, while the lower part is hinged to the dash board. The latter provision allows of the double fold, top over bottom, top and bottom over hood, which is so pleasant on warm days. Both of the joints are locked in the extreme and all intermediate positions, so that the top part alone, or both the top and bottom may be inclined. More than this the construction allows of this inclination being either toward the driver or away from him, thus, with the upper part vertical at the forward edge of the top, and the lower part sloping from the dash board line out to this, the position is perfect protection against fog or rain, while the shield is such a distance from the driver that he is enabled to see the road ahead very clearly, even with a clouded or befogged glass.



Spring Holding Mezger Wind Shield in Place (A & B), Also Action of Friction Automatic (C)

Emil Grossman—This firm, besides making "Redhead" spark plugs, and divers other automobile products, is the maker of the "Hydraulic" windshield and other types of the same general character. In this type of windshield, besides the automatic feature which prevents the shield from collapsing suddenly, French plate glass, very carefully annealed, is used, and, in its application, adequate means are taken to securely fasten the glass to prevent breakage. The metal work is very neat, has all the elements of needed strength, and a grade of liquid is used in the spring dashpot which remains at a constant state of viscosity under all temperature changes.

Hill Manufacturing Company—This Buffalo concern exhibited at the Palace show a full line of self-acting or automatic wind shields. These fold and are made up on a framework of 7-8-in. brass tubing, with 1-2-in. supporting rods. The shield is made in three differing widths, 40, 42 and 44 inches, which will take care of any ordinary dash board now used. The upper half of the shield may be tilted forward or backward at any angle, being held where set by compression.

Metal Stamping Company—The spring catch, which holds the shield in the folded or open positions, is the feature of this New York City product. It is made in two widths, both 29 in. high, these being 41 and 44 in. The catch is made sloping or tapering to a narrow edge, two semicircular notches being cut out of it on the two sides of the rod. Within the tubular framework of the shield are placed two spring-retained catches, one above and one below the parting, which catches slip into the notches through the impulse given them by the springs. This enables one to jerk the top out of its vertical position, and let go of it. The swing is circular and the catch at the bottom will retard the swing, and catch and hold it in the folded position.

This construction also does away with nuts, bolts or clamps, being complete in itself. The glass used is the best, selected, polished, French plate, clear and free from flaws. The frame is of heavy brass tubing mounted upon a mahogany filler board.

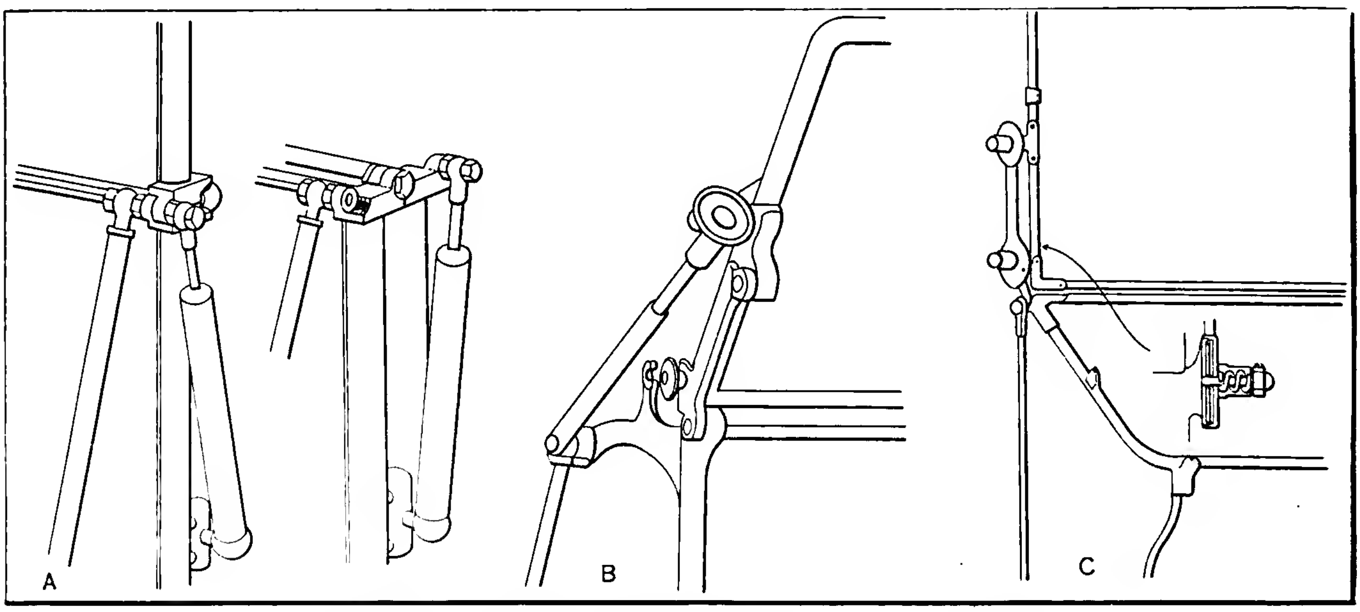
Novelty Manufacturing Company—Ajax is the name of the wind shield made by the automobile department of the Waterbury, Conn., supply house. It is described as strong, steady, silent, each one of these being considered a vital feature. At the Garden show this firm attracted not a little attention by giving away a small case, containing a mirror, powder puff and some powder. Needless to add this made the booth attractive to the ladies, while the result was to make the ladies more attractive.

Troy Carriage Sunshade Company—While many widely differing types and sizes of wind shields are made, the ones featured are numbers ten and twelve. The former is built, the makers say, to outlast the car, which speaks well of the construction. This has the lower part fixed, but the top or upper half, may be set in any one of four positions besides the most usual vertical and folded positions. A double pivot hinge allows of an offset position, that is the plane of the top either forward or back of the plane of the lower fixed part. Neither of the two models possesses any thumb screws to get out of order, or require time for manipulation. The upper sash, so-called, is self-locking in any position, the lock being a positive one. The lock is aided by crucible steel springs in keeping the contact parts in constant juxtaposition.

Like model ten, model twelve has the top hinged, but in addition the bottom is hinged to the top of the dash in a similar manner. This gives the bottom as many possible positions as the top, namely, four besides the vertical and horizontal ones. The whole wind shield, then, has all of the possible combinations of the two, considered collectively.

Vanguard Manufacturing Company—These Western makers have given the wind shield the name of the firm—Vanguard. It does not rattle, in fact, the makers say that it can not rattle. The shield parts in the middle, the brass binding along the two middle edges being very narrow, so narrow as to be practically invisible. The hinge is a two-radius one, so that the top part will swing down at the back without hitting the steering wheel, or in any way interfering with it. A clamp at the end of the two parts is hinged to the lower part, and held to the top by means of a thumb screw with a very large milled head. This clamping strip is also hinged to the bottom, so that when the top is swung over, the strip turns over with it, and the thumb screw comes into play again to lock it in the down position. The wood frame is of selected material, while the rod and bindings are of tubular brass, all other mountings, including the hinges, being of very heavy, machined brass.

Vehicle Apron & Hood Company—New and different in every respect are the 1910 wind shields of this company, the 1909 line having been discarded entirely. The newest shield is of the automatic variety, folding either forward or back. The folding action is controlled by a spring of oil-tempered steel, which is concealed in a cylinder at the ends or sides of the wind shield parts. In conjunction with the plunger operating the cylinder, this spring comes into action, the plunger having a large double-acting leather valve which controls the passage of the air in altering the position. The combination of the two is said to be very effective. The frames are of heavy brass tubing, and the hinges of manganese bronze castings, this material being well known for its wearing qualities and strength. The rods which brace the shield are of brass, and adjustable for length. Rattling is avoided by mounting the glass in a channel-shaped rubber.



Mechanisms of Hydraulic (A), Sprague (B), and Troy (C) Wind Shields

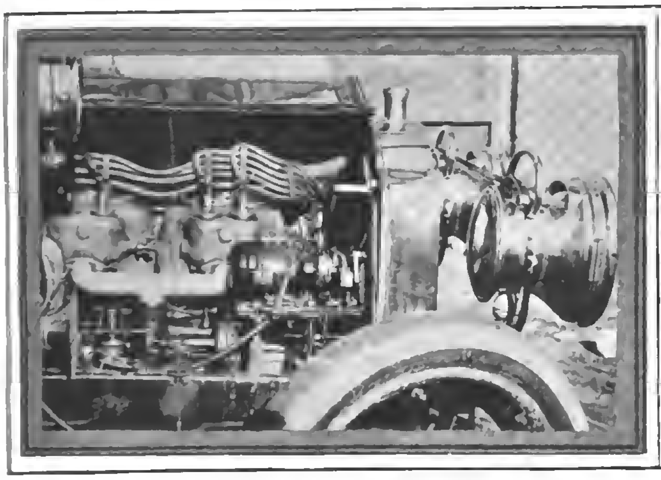


Fig. 1—Ward Leonard electric lighting dynamo shown on place beside the motor of an automobile, indicating compactness

Electric Lighting Takes on Significance

STORAGE batteries now seem to be of the greatest value in connection with gasoline automobiles due to the facility they offer in the process of lighting. In electric vehicle work this question of lighting has proven to be so pleasing, safe and reliable that autoists outside of the electric vehicle field have awakened to many of the possibilities and are strongly urging action.

Commercial activity is always but a reflection of a demand and, in view of the pressure which has been brought in this connection, makers of electrical equipment, as lamps, dynamos and storage batteries, are endeavoring to supply the requisite equipment. That attention to this matter in a commercial way has resulted in several solutions of the problem is now well established, and, among the systems which attract notice, that illustrated in Fig. 1 possesses more than commonplace novelty. This system was brought out by the Ward Leonard Electric Company (Bronxville), New York City, and, as the illustration portrays, it is compact, readily nested under the hood alongside of the motor, and as to its ability to serve, there seems to be no question unless to count its virtues.

WARD LEONARD LIGHTING DYNAMO FOR AUTOMOBILES

This system includes a dynamo D, taking its power from the automobile motor, through connection with the half-time gear system, or in any suitable way, and since the automobile motor runs at a variable speed, a means is at hand for regulating the voltage of the dynamo, in this case utilizing the principle of field control: that is to say, the field excitation is varied to suit the requirement as indicated by speed changes.

The drive takes place through a magnetic clutch which is so contrived as to eliminate the need of adjustment for any purpose. The clutch is so small that it adds but little to the dimensions of the dynamo, hence the objection which takes expression by way of comment on the space demanded is uncalled for and experience with this device affords evidence of its competence.

STORAGE BATTERY FLOATS ON THE SYSTEM

The storage battery, which is relatively small, floats on the system: that is to say, the battery, which may have the required number of cells in series as six, is connected across the terminals of the dynamo, hence the battery is in parallel with the dynamo armature, and since the fields of the same are shunt wound, they too are in parallel.

The dynamo is so wound that it is capable of charging the battery when the number of lights in circuit are less than the dynamo capacity, and the difference in potential across the terminals of the battery is that of the dynamo and the lamps in circuit at all times.

The dynamo has a capacity equal to the requirement of a large limousine; side-lights, searchlights, inside illumination and tail lighting being included. The battery, when floating, is always available to take the load if the dynamo is shut down, which would be true were it necessary to stop the automobile motor for any purpose, and when the automobile motor is started again the storage battery will then be charged automatically.

The wiring system in this application is so arranged that the ignition and lighting systems are quite independent of each other. The lighting circuit is what is technically designated as a "metallic circuit," which is another way for saying that the circuit is completed for both outgoing and return, rather than to use a so-called ground return, which is a technical way of stating that some part of the metallic frame work is utilized for the return circuit.

The advantage derived from employing a metallic circuit for the lighting system, entirely aside from questions of insulation, lies in the non-interference of the lighting system with hte ignition work; ignition wiring is "grounded," and were a grounded lighting system to be used also it is possible that some form of trouble would be experienced.

The storage battery used in this class of work is very interesting and will be the subject of separate discussion in an early issue of The Automobile. For the present it will suffice to state that, while any battery, if it has the required number of cells in series, will do the work, provided it is capable of being floated on the system and has a characteristic which will accord with the nearly constant voltage requirement as it is represented in lead storage batteries of well-known forms.

The new idea, however, seems to be in favor of a relatively substantial battery, one which will float on the system for, say, three years, and demand little or no attention in the interim. This is possible if the battery is very substantially made, and it is interesting to note that the introducers of this form of electric lighting decline to take notice of the question of weight with the idea of reducing the same to a low point.

It is claimed that the weight should be enough to assure permanence of lighting without attention, and were a battery of high weight efficiency selected, it is reasonable to expect that "buckling" and other battery troubles would be more likely. The plan then, considering the newer systems, is in favor of the greatest possible stability, excellence of lighting and low cost of maintenance even in the event of lack of care.

The batteries are especially sealed, loss due to "agssing" is reduced to a low ebb, and evaporation of the water of the electrolyte is aborted. Gassing does not transpire because the battery

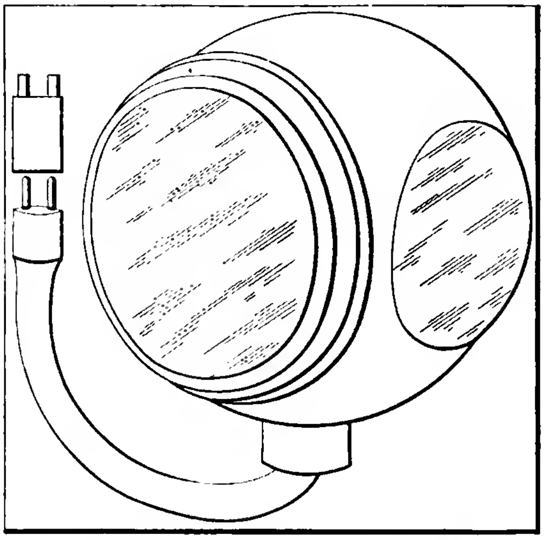

Fig. 2—Dietz tail lamp designed for electric lighting, and fitted for tungsten lamp, with suitable terminals

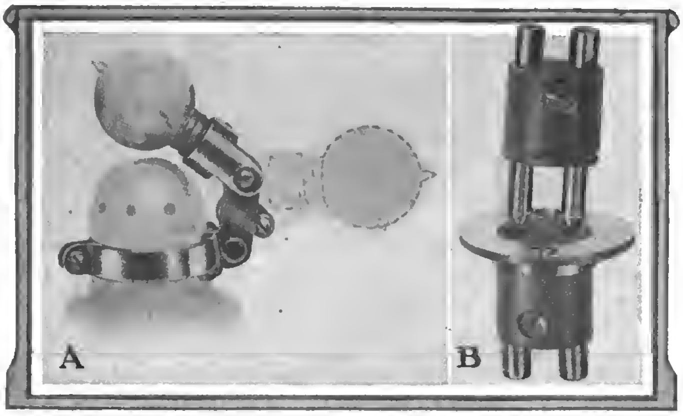

Fig. 3—Culver-Stearns electric combination lighting fittings; (A) presents lamp attachement, and (B) portrays the terminal

is never charged to a high potential difference—it floats—and the specific gravity of the electrolyte (liquid in the cells) should hold to a nearly constant level at all times. It is true, of course, that best results from any battery will follow if the cells are given the least bit of attention from time to time, but in this new form of lighting it is the purpose to reduce the matter of the care of the battery to a minimum. This will be quite possible in view of the present state of the art, from the battery point of view.

BATTERIES ARE USED WITHOUT DYNAMOS

This statement of the methods employed in lighting work would be incomplete without including one or two other variations which seem to be stable. In many cases, in the absence of a dynamo, the battery is of sufficient capacity to do the lighting and ignition work. This class of battery is selected for the service to be rendered and, in view of the extent to which lighting batteries are used, it is believed that the subject should be treated separately and at some length. This will be done at an early date.

LAMPS ARE MADE IN COMBINATION FORM

In connection with electric lighting the lamps are made in combination form; either acetylene or oil lighting may be taken advantage of in connection with the electric lighting, so that if the electric system should become deranged, the auxiliary system will serve in the emergency. Fig. 2 presents a Dietz electric tail lamp which is used to illustrate the nice way in which this class of work is being cared for by the makers of lamps, and, at the option of purchasers, lamps of this character may be had with an oil well and means for the use of oil burners when the emergency arises.

Fig. 3 presents three other forms of lamps, they being used ordinarily with electric (tungsten) lamps in place, and as an emergency measure the electric lamps may be swung back out of the way, and the oil burners may be lighted.

STABILITY IS PRESENT TO A MARKED DEGREE

In these methods of caring for the lighting question, it is the aim of the designers to eliminate contraptions and make the parts to suit the work to be done. It is now a recognized fact that good lighting is, like good brakes, insurance of a high order; indeed, it is useless to have good brakes if the lighting is not well cared for, on the ground that to arrest the motion of a car it is necessary to apply the brakes in time; no matter how good and effective the brakes may be, unless the distance is well regulated, the car cannot be brought to rest quick enough to serve the purpose.

CULVER-STEARNS ELECTRIC COMBINATION FITTINGS

As an illustration of the manner in which electric combination fittings are being made up, reference is had to Fig. 3, in which (A) is a fitting for a tungsten lamp to an oil lamp, and (B) presents a double pole terminal for the writing to lamps. These fittings are well made and appropriate to the needs.

Fig 4 of lamps made by C. T. Ham Manufcturing Company, Rochester, shows how the lamp makers are handling this phase of the problem. (A) represents the "Mars" tail lamp, (B) is the "Meteor" side-lamp, and (C) is the "Coupé." If so desired, these lamps may be fitted with electric combination fittings for tungsten lamps. It is a source of much regret that the whole electric lighting situation cannot be handled in a single number of The Automobile, but it will be the aim to give this matter much attention from time to time, and in the long run cover the whole situation. The interest taken by autoists at the two last shows rather goes to prove that it is a live subject, and that electric lighting is now on a very substantial basis seems to be a settled matter.

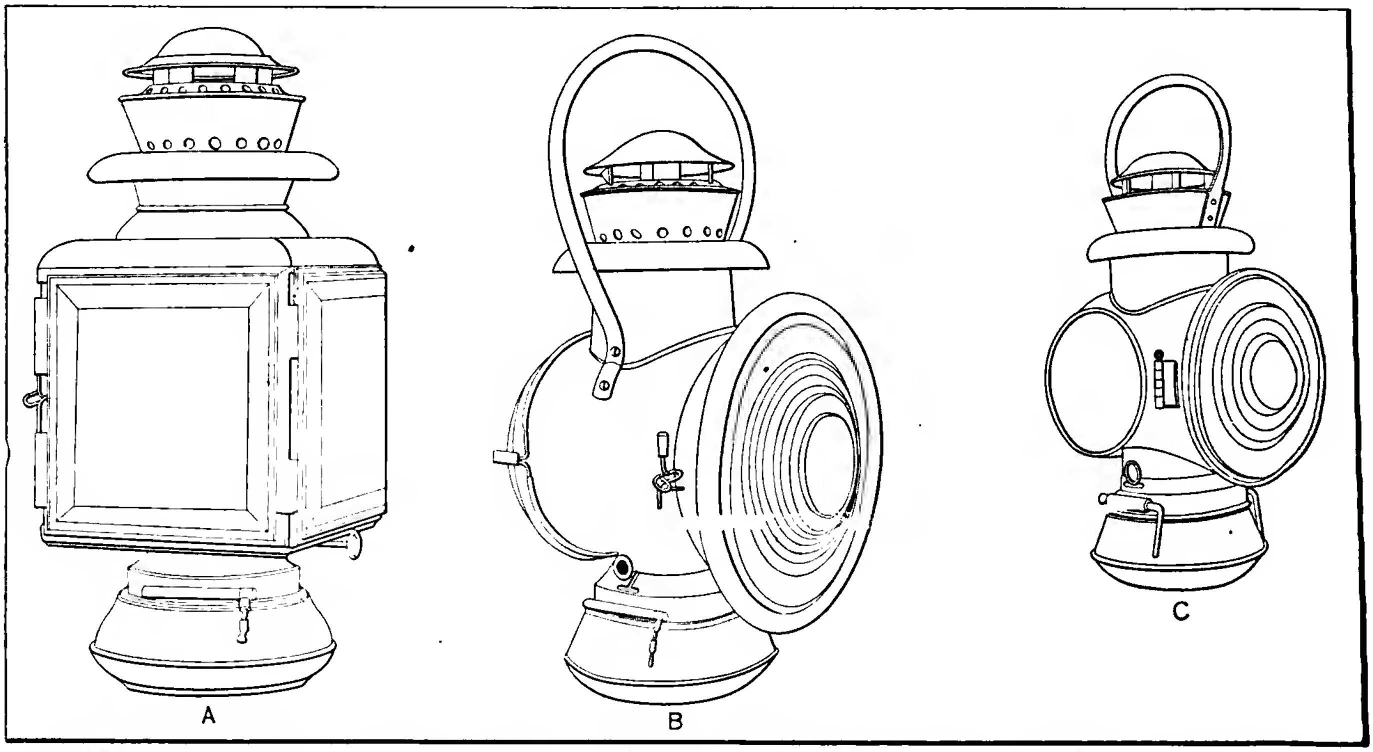

Fig. 4—Ham types of lamps for combustion lighting; (A) presents the "Mars," (B) shows the "Meteor," and (C) depicts the Coupé

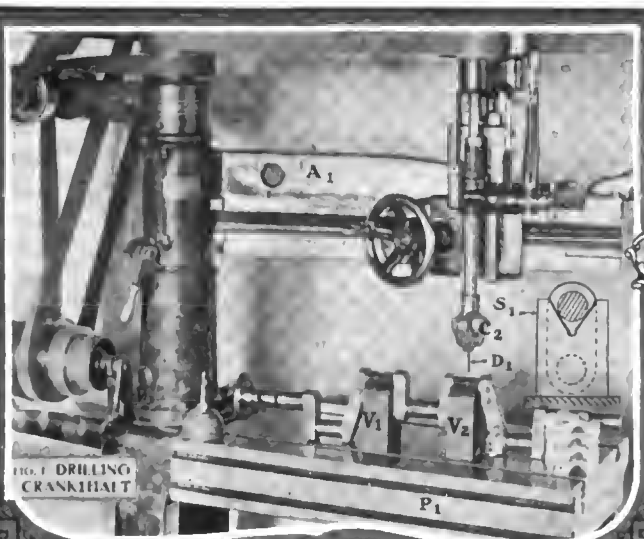

In the Garage Repair Shop

By Thos. J. Fay

Fig. 1—Method of drilling crankshafts, using a radial drill, V-blocks and a little skill

THOUSANDS of problems confront the garage repair man and in many instances are difficult to solve, moreover, the work has to be started on a speculative basis in many cases, and if it remains in the land of speculation after the owner of the car pays the score, it is not a matter of great wonder. The bill will be no smaller on this account; the repairman is entitled to pay for speculating as well as for working; risk belongs to the owner of the car.

How to treat this problem intelligently, is a matter which puzzles the editorial office more, perhaps, than any other one matter, and, in the long run, it is very likely that, to start from the ground, and work up, is a necessity. If this way is to prove to be right, it is necessary to start with the very methods used in the plants in which the automobiles are made, on the count that, a repair, if it is anything, is but the process by which the parts required are made and installed. That the makers know how to produce these parts, is proven by their presence in the cars, and the question of quality is beside the repair problem, on the ground that good or not so good the parts have to be made for the specific undertaking if the owner of the car is to realize further service.

INGENUITY TAKES THE PLACE OF TOOLS FOR REPAIRS

It is not to be supposed that a garage repair shop will have at its disposal all the generic types of machine tools which will be found in well-equipped manufacturing plants, but it will be one of the aims in this series of articles to show how a given operation can be consummated in many different ways, thus enabling the "provincial" garage with limited equipment to undertake even difficult tasks, although hampered by lack of facilities.

To some extent simplicity will have a bearing, that is to say, some of the methods which will be described will be so out of keeping with the practices in the "big" well-equipped garages that in the absence of fair consideration of the many angled problem, garage repair men will feel called upon to criticize—let the criticism come; tell of a better method; it will be afforded a resting place in the columns of THE AUTOMOBILE.

Since a garage, if it runs a repair shop, must cope with all sorts of jobs ingenuity must take the place of equipment more often than not, and it will be one of the specific undertakings to afford an insight into methods which will serve even when the tools which are best are not available. To illustrate this point it is enough to say that a drill press, for instance, is likely to be available in even the most poorly equipped garage repair shop imaginable, and it should prove of advantage to some to know in how many ways a drill press can be made to serve, moreover, without countenancing an inferior repair job.

Crankshafts are of such great importance in power plant work and they have to be so intelligently treated, that one is taken as the first thing shown. In this case a radial drill, Fig. 1, is shown in position for drilling the oilholes on the connecting rod pins, this being a rather troublesome operation. The crankshaft C1 is set up in V-blocks V1 and V2, they being high enough to bring the "work" up above the face of the platen P1, to clear the flange and throws of the crankshaft, so that the frame will rest in the V-blocks as the section S1 shows.

The round part of the shaft rests in the V-blocks and self-centers so that the tendency to work out from under is but slight and may almost be neglected. With the work in place and level with the face of the platen, all that remains is to chuck the drill D1 in the chuck C2, and swing the arm A1 of the radial drill around and in line with the work. By means of the travel of the drill mechanism the drill may then be centered and if the chuck is a suitable one it will hold the drill sufficiently true to accomplish the task. This illustration seems to be one with possible trouble to contemplate because of lack of sensitiveness of the drill. There is something in this view; sensitiveness, under certain conditions, is absolutely necessary.

One of the advantages of illustrating methods used in manufacturing is here clearly brought out, it being the case that this big tool is actually used in the Moon plant for just the work which is here shown, and the timid repair man, lacking in broader experience, perhaps, will be able to advance with greater confidence. There is no reason why a repair shop should not undertake the replacement of a crankshaft, even if it is the kind which is drilled out for oil ways, but it may come as a surprise to some that it is this "drilling out" that takes time and requires some skill.

KINETIC BALANCE OF ROTATING PARTS

In working on parts which have to rotate at high speeds in service, it is necessary to have a nearly perfect kinetic balance. Fig. 2 illustrates the method in vogue for ascertaining a true "static" balance, that is to say, the balance which is necessary when the parts are not in rotation. For static determinations a set of balancing tracks T1 and T2 are placed on an even foundation, and when the work is placed on the tracks, it should come to rest in any position in which it may be placed. In the particular balancing equipment shown, the rest on the foundation is through leveling screws, L1, L2, L3 and L4, which is behind, hence does not show. This ability to perfectly level the balancing equipment is a very good idea which is in vogue in the

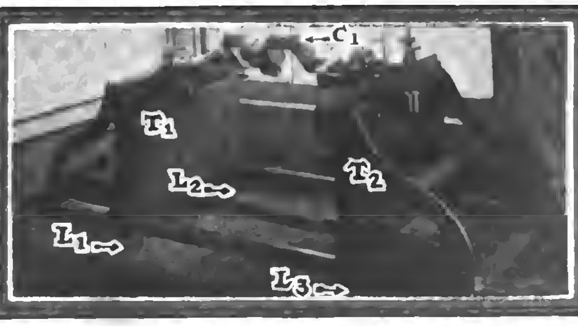

Fig. 2—Equipment used to determine the static balance of crankshafts showing method of leveling the same

Thomas plant at Buffalo, and some of the well-equipped garage repair shops have means at hand for ascertaining the static balance of the members which have to rotate.

A kinetic balance is a condition which must be arrived at in the designing process, hence the repair man does not have to cope with it as a rule. There is this to be said, however, when a repairman undertakes to improve on a designer, he must see to it that the kinetic couples are all satisfied. The mere fact that a crankshaft will prove out on a set of balancing rails, is no proof of its ability to run in a good state of balance.

Kinetic balancing must, of course, follow the condition of static balance, it being true that a part which is not in static balance cannot be balanced in a kinetic sense. For a perfect kinetic balance the conditions of a well-made six-cylinder crankshaft come near to satisfying the needs, and in future, as the situation would seem to warrant, this matter will be delved into at some length.

IN REPLACING A CRANKSHAFT AFTER REPAIR

It is first necessary to determine if the journals are all round; this is done by using a micrometer, making measurements across the diameter at the middle, and at the two extremities, then repeating these measurements across the diameter, but 90 around in order to determine if the journals are round.

The crankshaft, if the main bearings M1, M2, M3, M4 and M5 are not on the same axis, will fail to deliver satisfaction, and this form of trouble has been heard of. If, before assembling, the crankshaft is set up in centers in a lathe, it will be an easy matter to ascertain if all the bearings were turned and ground while on the same centers by the simple expedient of revolving the crankshaft on its centers E1 and E2, and by means of a piece of blue chalk note if contact (shown by the chalk line) is equal all around; shown in Fig. 3.

If the first try indicates that the centers are not common, the amount of the difference will then be a matter to be found, which to do requires a further investigation, using instruments as surface gauges, or of greater precision, in the process. Should the condition be acute, it is doubtful if the crankshaft can be used at all. That the trouble must be removed is one of the points which can be accepted without discussion, and if it is more than can be removed by setting the crankshaft up in centers in a grinder, the case is hopeless, unless it is possible to reduce the diameter of the main bearings M1, M2, M3, M4 and M5 enough to make up for the error, and allow of grinding sufficiently to bring the journals round (to the new diameter) and on the true axis of rotation. In deciding to reduce the diameter of a crankshaft for the purpose of correcting an error, it must be remembered that ability decreases as the cube of the diameter, and under such conditions but a slight decrease in diameter makes a considerable decrease in ability.

If the crankshaft is true on centers, referring to the main bearings, the next thing to do is to scrape in the bearings. This operation is performed by blueing the journal surfaces, using Prussian blue, and applying just enough of it (by smearing over the surfaces with the blue on the end of the index finger) to evenly color the metal all over the bearing surfaces. An excess should be avoided.

With the journals thus prepared, if the "brasses" are quite close to size (which may be determined by a dummy shaft of the exact right size layed in placed of the crankshaft) the crankshaft may then be substituted and rotated, to cause the blue to spread out over the surfaces of the brasses. If the brasses are to the right size the blue will show all over the surfaces which should bear.

BEARINGS SHOULD BE BACKED OFF IN TWO PLANES

Lubricating oil actually takes up room if it is present, which it must be if bearings are to be run for any length of time, even when the service is but slight; in a crankshaft, where the service is most strenuous, there is no possible chance of realizing service if the lubricating oil cannot work in and float the shaft on a film of the same. To be sure that the oil will work in, the brasses are scraped in such a way that they do not bear all around the diameter. In scraping it is the idea to back away (by scraping) toward the horizontal center line, as shown in the section S1, so that the shaft bears on the top and bottom and for a distance for about 1-3 around. When this condition is arrived at, the blueing should show, but there is no need of backing off more than a few thousandths of an inch at the points of no bearing, it being the case that oil will get by even if the distance is considerably less than five thousandths of an inch.

When the scraping is continued until the bearing around the girth is right, the next thing to do is to back off the metal in the axle plane. This is done by scraping in such a way as to leave a pair of truncated cone shapes (so to speak) with the crest at the center. This leaves the bearing surfaces firm at the center, and as the wedge-shape bearing increases toward the ends of the bearings, the pressure becomes less, with slight indication of blue at the outer ends.

The amount to back off in the axle plane is difficult to fix in exact measurements, but there is this to say: Trouble will be more likely when parallel scraping is resorted to than when the bearing metal is scraped away, for if lubricating oil is enabled to enter by scraping back toward the horizontal center around the girth, this same lubricating oil must be given a vent or it will stay in, prevent new oil from entering, and in a very short time it will have its lubricating qualities worn out, grit will accumulate, and the bearing will "freeze." The section B1, B2, B3, and B4, indicate, to an exaggerated degree, the backing off process in the axle plane of the journals.

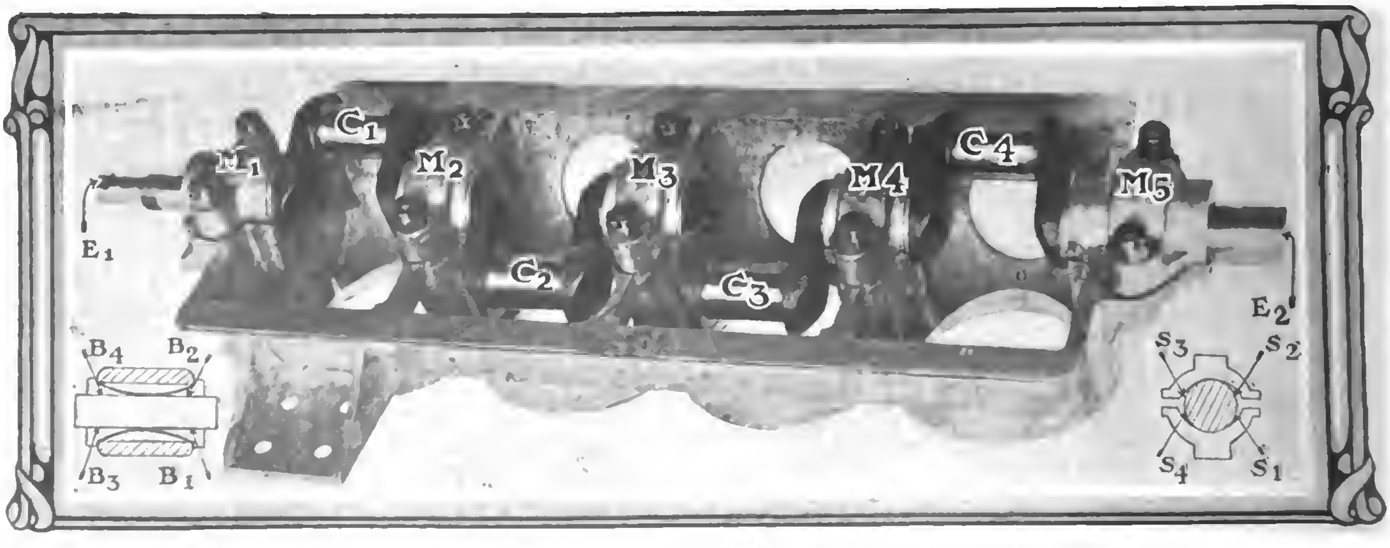

Fig. 3—Crankshaft in place after bearings were scraped in and liners reduced to requisite thickness to let cap down to contact

LINERS ARE NOT ALWAYS USED IN CRANKSHAFT WORK

When the two halves of the "brasses" are so accurately made that they come together properly, which should show in the trying process with blue on the journals, it is not necessary to consider the use of liners. If the fit is not "neat," then it is necessary to employ liners, and in this practice it is better to allow for them beforehand, and use several thicknesses of suitable material for the purpose. Paper is frequently employed, it being the case that "detail" paper, such as is used for detailing out work in the designing office, comes in several thicknesses, ranging from 0.005 to 0.015 inches, and with this selection of thicknesses it is possible to arrive at a good fit in a short time.

While paper works very well indeed, and seems to stand up under service conditions, even so many motor repair men prefer sheets of copper, using them of two or three separate thicknesses to facilitate arriving at a good fit of the bearings. This method would naturally be more satisfactory to a car owner on the ground that he might then be able to tighen up the bearings (without going to a repair shop), in the due course of time, by the simple expedient of removing a liner; if there are several, and all of a different thickness, he may then take his choice of them, removing the ones which will afford the nearest to what he might be willing to designate as a good fit of the bearings.

WHITE METAL USED IN CRANKSHAFT WORK

The average repair man must rely upon the vendors of Babbitt metal for the quality of the material, and yet when all things are considered, the two horns of the dilemma are: (a) The requirement is the most exacting of all applications of this class of material. (b) Babbitt is the most varied metal which it is possible to purchase.

It is a trick worth noting, the method by which clever repair men "fetch up" inferior Babbitt so that it will serve in a crankshaft job with reasonable certainty. The process consists in purchasing the best babbitt, according to the fellow who keeps all his grades in one bin, and after receipt melt down in an iron pot enough (nearly) to do the contemplated repair. When the Babbitt is at a fairly high heat (so that it "sparkles" the charcoal which is placed as a powder over the surface to prevent oxidation), tin is added in quantity sufficient to render the metal "cold short."

It is easy enough to ascertain when the right amount of tin is added; the metal (a little of which can be taken from the pot in a ladle, and quenched in water), will then fracture readily. It is not necessary to bring on an excess of the condition designated as "cold short," but it is better to do so than to let the metal go without enough tin in it to bring it up.

Instead of dealing with this relatively inferior white metal, even when it is tin corrected, it is better to have on hand a quantity of Fahrig metal, Parsons bearing metal, or other equally good material of this character as used in motor crankshaft bearings. Fahrig metal, according to analysis by Robt. W. Hunt & Co., is composed of:

CHEMICAL COMPOSITION.

Tin, 90 per cent.
Copper, 10 per cent.

This analysis is subject to such variations as will naturally creep in by way of such impurities as reside in copper and tin; the total of the impurities makes no great difference in this class of work.

In working this metal, in order to realize proper results, it is necessary to heat it to a dull red heat. This is extremely important, and many failures are directly due to pouring at a low heat.

PRIVATE GARAGES SHOULD LIMIT THE FIRE HAZARD

EVERY district has its special fire risk, and the insurance question is looked after by local boards of fire underwriters, who have in mind the local conditions and the fundamental risk involved; no set of rules, under the circumstances, will serve for every case, and when private garages are projected it is well to consult the local board, as well as to file plans with the "building department" having jurisdiction. In a general way, even though absolute rules may not be given, it will be possible to offer a set of rules such as will afford an insight into the intricacies of the requirements, and enable the prospective owner of a private garage to appreciate the necessity of proceeding with care and discrimination.

Ashes must be cared for in metal cans.

Blower system must be provided with metal conduits connecting each machine with shaving vault, such conduits passing to the outside of building at each floor.

Boilers must be outside of building, or if located in extensions, must be cut off by standard fire door. In wood-working establishments a door must be provided at each side of the communicating opening.

Buckets—There must be two buckets of at least 10 quarts on each floor, including basements, for each 1,000 square feet of floor area, same placed on permanent shelves, hooks or racks elevated not less than 2 feet nor more than 4 1-2 feet above the floor. Buckets to be painted red and marked "Fire" with letters not less than 2 1-2 inches in height, to be kept full of clean water and inspected once a week. If water in buckets is likely to freeze in cold weather, enough salt to be mixed therewith to prevent freezing. In rendering establishments, paint, oil and varnish stocks, or any other place where inflammable liquids form part of the stock, one-half of the number of buckets must be filled with sand instead of water. Wooden buckets will not be accepted.

Ceilings or side walls must not be paper or cloth or wood.

Communications must be provided with standard fire doors at each side of the wall constructed and installed in accordance with rules of the New York Board of Fire Underwriters.

Condition—Premises must be cleaned up and kept clean. Stove pipe holes must be closed up. Sawdust must not be used in spittoons or for catching oil or drippings. Broken plastering must be repaired.

Drying—Drying rooms must be constructed in accordance with the requirements of the New York Board of Fire Underwriters.

Fire Heat—Glue must be heated by steam. Melting of pitch, rosin, wax, paraffine, sulphur, etc., must be by a safe method. Soldering irons must be heated by stationary gas mufflers. All low gas stoves shall be placed on iron stands or the burners shall be at least 6 inches above the base of the stoves and a metal guard placed 4 inches below the burners and all wood work under them shall be covered by metal. Connections must be made by iron piping; rubber tubing must not be used.

Flues—Chimneys must be built of brick and rest on the ground. Stove pipes must run horizontally into the chimneys. Stove pipes must not run through floors or partitions.

Floor Openings—Openings for stairways, elevators, dummies, etc., must be closed or enclosed so as to prevent the spread of fire from floor to floor. Dumb waiter shafts open in the basement must be provided with the same kind of doors as floors above. Hatches with automatic attachments must be arranged to close the shaft even when the car cable is down, with not over 2 square inches of uncovered opening.

Gas Brackets—Open gas lights in show windows must be protected by globes. Swinging gas brackets must be made stationary or proper guards must be provided for same. Metal must be put on ceiling over all gas jets less than three feet below same.

Heating—Steam heat must be substituted for stoves or furnaces to secure removal of charge for latter.

Lighting—Gas or electric lamps must be substituted for oil lamps.

Oily Waste or Rags—Must be cared for in self-closing metal cans.

Packing Materials—For loose packing materials wherever used a covered bin must be provided, not larger than 4 x 4 x 4 feet (64 cubic feet) lined with heavy tin extending well over edges of the same, joints locked and tin nailed under joints in the same manner that the covering is applied to standard fire doors. Cover must have substantial fastenings and fit closely.

Shaving Vault—Must be of brick, ventilated, and located outside of building. If adjoining boiler house the opening to boiler room must be at right angles to fire hole of boiler and not nearer thereto than six feet; such opening to be protected with fire door.

Shutters—All openings (windows, etc.) in exterior walls excepting those on street front, must be provided with fire shutters or doors constructed and attached in accordance with rules of the New York Board of Fire Underwriters.

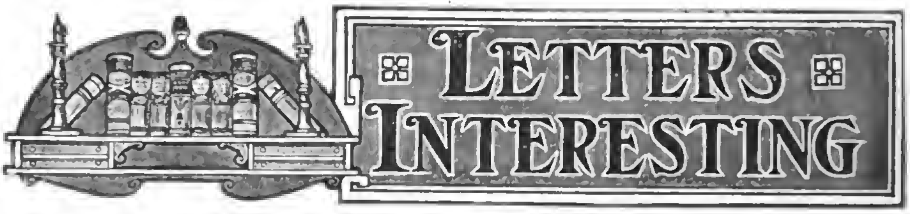
Skylights—Must be of rough glass 1-2 inch thick (wire glass preferred) supported in substantial metal frame, but when over elevator shafts thin glass in metal frame with wire mesh over should be used.

Storage of Oils, etc.—All oils, varnishes, turpentine, alcohol and similar articles must be stored outside of buildings.

Unsafe Heating Apparatus—Flues, stoves, furnaces, steam pipes, etc., reported unsafe by the New York Board of Fire Underwriters must be corrected in accordance with the specifications of the Heating Department of that Board, which will be furnished on application to the Board, and which must be signed and returned when fully complied with.

Watchman and Clock—Watchmen must be maintained nights, Sundays and holidays, or all the time when property is idle. Watchmen must patrol the property, making records once each hour on an approved clock, records to be dated and preserved in good order for examination by inspectors.

Watchman's Lantern—Must be of protected tubular make and only signal, lard, or sperm oil shall be used therein.



CYLINDER OIL CONGEALS

Editor THE AUTOMOBILE:

[2,139]—This is my first offense, but it seems serious enough to risk asking about. I have been draining my water system—I have a four-cylinder water-cooled automobile—this fall, but find that with this cold snap and the thermometer going to six degrees below, and seldom getting higher than 20 above during the day, that the oil in the cylinders congeals to the extent that I cannot turn the engine over, unless I fill the engine with hot water. I now have a supply of denatured alcohol on hand and propose to keep it right along, so will not have to drain every time, but while it will not freeze, it will no doubt get as cold in the cylinders as before. So, what can I do to make the engine turn over more easily? I keep my machine in a barn with a cement floor, without any heat, and it gets pretty cold these mornings. I have been taking "The Automobile" only a few months, but you have a life subscriber in me from now on!

Clinton, Mo. E. T. MONTGOMERY.

Aside from selecting the oil with care, so as to obtain one which will remain liquid at the lowest temperature encountered, there is very little that you can do, unless you want to install a heating system in the garage. This latter would be a very wise move as it will not only insure against a repetition of the trouble of which you speak, but will also result in the machine being kept in better condition at all times, as there will be hot water at all times, to wash it off, while the garage being heated will insure a comfortable place in which to do repair work and make adjustments. All these things contribute to the longevity of the machine, and can be measured in actual dollars and cents. If you were to look into the cost of installing a simple heating arrangement, you would be surprised at its lowness. If the barn is small, a simple stove will do the work, and this only needs to be kept burning during the night, at which times a very low fire will answer the purpose. If the barn is very big, a stove with some very simple piping around the room will do the work.

It would seem as if the time you waste every time you want to take the machine out, would be worth something to you. Capitalizing this, won't you find that you are money in pocket in installing a heating system?

TO INSERT PISTONS

Editor THE AUTOMOBILE:

[2,140]—How can you replace the piston in a single-cylinder engine when it is taken out at the top? The rings catch. I have asked many experts, have bought all the books on kinks in repairing, and still cannot seem to get the piston in. When the cylinder is taken off and the piston removed through the bottom it is an easy matter, it can be entered by springing each ring with the hands, when entering it into the cylinder, but I cannot replace it when taken out through the top.

Mooers, N. Y. W. U. TAYLOR.

This repair may be effected by the same method as is used to remove rings from a piston; that is, by the use of very thin, flat pieces of steel. Only, in the removal of the rings, the steels are inserted below the rings, while in the insertion of the piston and rings into the cylinder, the steels are set around the outside.

Make or obtain three or four very thin flat pieces of steel, the thinner the better. Place these around the piston and rings, which should be in place as well as the connecting rod, spacing them equally. Then with a rubber band, string, or something of that sort, spring the rings in close to the piston, as close as is possible, paying particular attention to the lowest ring.

Now insert the whole outfit into the cylinder through the open head, down as far as you can, which will doubtless be down to the bottom ring or the lower end of the flat steels. Then draw the steels upward slowly so as to partially uncover the lowest ring, say so as to uncover about half of it, at the same time forcing the piston into the cylinder. If the steels hold the rings into the grooves in the piston as they should, the lower ring will enter the cylinder bore. Then the steels may be drawn off of that ring entirely, and the piston pushed down until the next ring catches. Draw the steels up so as to half uncover this and repeat the performance described in connection with the first ring. This is simply repeated with each one of the rings, no matter how many you have, and should be successful in every case if manipulated rightly.

CARE OF TIRES IN WINTER

Editor THE AUTOMOBILE:

[2,141]—How is the best way to care for tires during the winter when the car is not in use? Should tires be washed clean when put away for the winter, or does water injure them? G. G. S.

Annandale, Minn.

When the use of the car is given up for the cold weather season, the car should be jacked up off of the tires, some air let out of them so as to reduce the pressure, and the whole washed very thoroughly, particular attention being paid to the removal of all traces of oil. Contrary to your implied idea, water does not harm the tires or the rubber composing them in the least, but oil and gasoline do. In case you wish to go into the matter a little further, and do a more thorough job of putting them up for the winter, proceed as follows:

After washing thoroughly, take the tires off of the wheels, take the tubes out of the shoes, paint the inside of the shoe and the outside of the tube with graphite, wrap both very carefully in cloth or heavy paper, paper over cloth being the best, then store in some dry, dark place, preferably where the temperature is very even all winter and not far from 30 deg. Fahr. Light is a great enemy of rubber, as is also heat; by putting the protective covering around the tires, then keeping them away from light and heat, there will be absolutely no deterioration, no matter how long they may be kept put away. This method of procedure is really worth the time it takes.

SAFE MAXIMUM SPEED

Editor THE AUTOMOBILE:

[2,142]—In your column of "Letters Interesting, Answered and Discussed," will you please give the maximum safe speed at which the average automobile engine may run. In other words, what is the greatest speed that the magneto of such a motor may have to stand? We have had an instance here of a Bosch armature being "shot" by racing the motor to get out of a "stall." Of course, this speed was excessive, but is not the magneto designed to stand such speeds?

Sumter, S. C. C. T. MASON.

In the usual case, the speed of the motor is only limited by the ability of the cast-iron flywheel to withstand the centrifugal force at that speed. The safe allowable linear speed, based on a liberal factor of safety, is about 6,000 ft. per minute. This, then, governs the speed, as knowing the diameter, it is a simple matter to get the circumference in ft. Then by dividing the safe linear speed per minute by the circumference, you get the safe allowable speed in revolutions per minute. Thus, to give a specific case, take a flywheel of 17 in., an ordinary size. The circumference of this in ft. is 4.45. Then, for a 17-in. flywheel the safe allowable speed is $\frac{6{,}000}{4.45} = 1{,}348$, or, in round figures, 1,350 r.p.m.

This, however, is figured with a factor of safety of 10, so that it may be exceeded slightly with safety. Using smaller flywheels, the speed may be increased in proportion, while with steel for the material instead of cast iron, the rotative speed may be increased in the ratio of the strength of the two materials.

The following speeds of a number of French engines are of interest as bearing on the subject, indirectly; De Dion, 1,400; Farcot, 1,500; Chenard-Walcker, 1,500; Darracq, 1,500; Sultan, 1,600; Renault, 1,600; Unic, 1,650; Sizaire-Naudin, 1,700.

Each and every one of these, to the best of our knowledge, is ignited by means of magneto, so that this list would seem to answer your question, at least as to safe practical speeds.

However, for racing purposes, the magneto is also used for ignition, and there these speeds are exceeded. Thus, the Arrol-Johnston (English) four-inch racer was tested up as high as 2,400 r.p.m., and is ignited by magneto, so that this rotative speed should be safe for the magneto armature. The English Napier is now magneto-ignited, and for the six-cylinder engine a rotative speed of 3,000 r.p.m. is claimed to be not only possible, but usual practice.

In your case, something else must have been the matter, as we have never heard of this trouble before.

ANSWERED AND DISCUSSED

BISSELL'S NEW HELICOPTER

Editor THE AUTOMOBILE:

[2,143]—The writer has been reading all you say in "Letters Interesting" about aeroplanes and begs to inclose herewith a sketch of a combination helicopter, aeroplane, parachute and gyroscope, all in one to make her safe, sane and reliable. The engine is at the bottom where it ought to be, and the "gladiator" sits in the middle behind the vertical shaft, where he is protected from all shocks and accidents. The propeller on the front is universal and can be turned in any direction. There are two guide planes in front of it, one smaller so if there is a severe side wind the planes can be reversd. The large plane is horizontal and the small one vertical. The guide handle also twists to tighten up on a leather strap that wraps around it and thereby push down on the spiral spring to loosen the belt that runs the front propeller so that all the power can be transferred to the vertical propeller which has adjustable blades.

One man can operate the whole thing himself. He gets on the seat, reaches up and gives the flywheel a whirl to start the engine, then he twists the little hand-wheel above his nose which controls the roof blades, and the machine rises. Then he lets go on the clutch and starts the pulling propeller, turning it well to the left side so he won't turn around himself, and gradually bringing this steering handle back to a position in front of him as the machine gets under way.

As there is very little head resistance this should be a fast machine. It can't be upset for obvious reasons, and the data already available indicates that a 20-horsepower engine would be sufficient to make it fly, as the whole apparatus, including a man and ten or fifteen gallons of gasoline wouldn't weigh over 400 pounds. Kindly advise me what you think of the scheme. "T. K."

Pittsburgh.

Another case where the proof of the pudding is in the eating. The only way to tell whether your machine is any good is to make one and try it. We doubt, however, if you appreciate the difficulties of using a single vertical propeller. With any sort of a propeller, there is just as much tendency for the propeller to stand still and the machine go around, as there is for the machine to stand still and the propeller go around. Apparently you intend to overcome the tendency of the machine to go around by means of the front propeller. It would be much more economical of power, though, if you used the vertical propellers turning in opposite directions, or other means of balancing the tendency directly.

We would like to know how you worked out the proportion of power to weight, and what authority you have for assuming that 20-horsepower acting on your vertical propellor will give a thrust of 400 pounds. Your weight, too, is doubtful. With a 160-pound man, an engine which cannot weigh less than 100 pounds, and 50 pounds of gasoline, you have but 100 pounds left for the framework and the propellers. The 80 feet of steel tubing in your fly-wheel-propeller rim will weigh more than that alone. A little consideration of the design, reproduced below, would seem to show that the inventor had not given enough thought to a number of salient points. As for instance, the adjustable blades at the rear, how do they clear the front end mechanism?

NO KEROSENE USED

Editor THE AUTOMOBILE:

[2,144]—We desire to call your attention to article on page 1049 of your December 16 issue, under heading "Troublesome Carbon." Replying to "F. H. T.," would say that he will have absolutely no trouble in getting his car started if he will immediately after cleaning one cylinder start the engine, and if the same is a four-cylinder car the three cylinders will be in working order and will soon get the fourth cylinder to firing properly. If the engine is started after each cylinder is treated with Prest-O-Carbon Remover there will be no trouble whatever in keeping the engine going and it will certainly clean out every particle of carbon. What we are especially interested in is your statement at the bottom of the column stating that it is believed to contain kerosene in large amount. Now we want to particularly caution you against making a statement that you know absolutely nothing about. As a matter of fact, there is not a particle of kerosene in Prest-O-Carbon Remover. We absolutely guarantee it in every way to do the work we claim it will do. We believe you realize the Prest-O-Lite Company has got too good a reputation and too large a business to try and push the sale of anything that is not high-class in every particular.

THE PREST-O-LITE COMPANY,
J. A. ALLISON, Secretary-Treasurer.

FULL VS. SEMI-ELLIPTICS

Editor THE AUTOMOBILE:

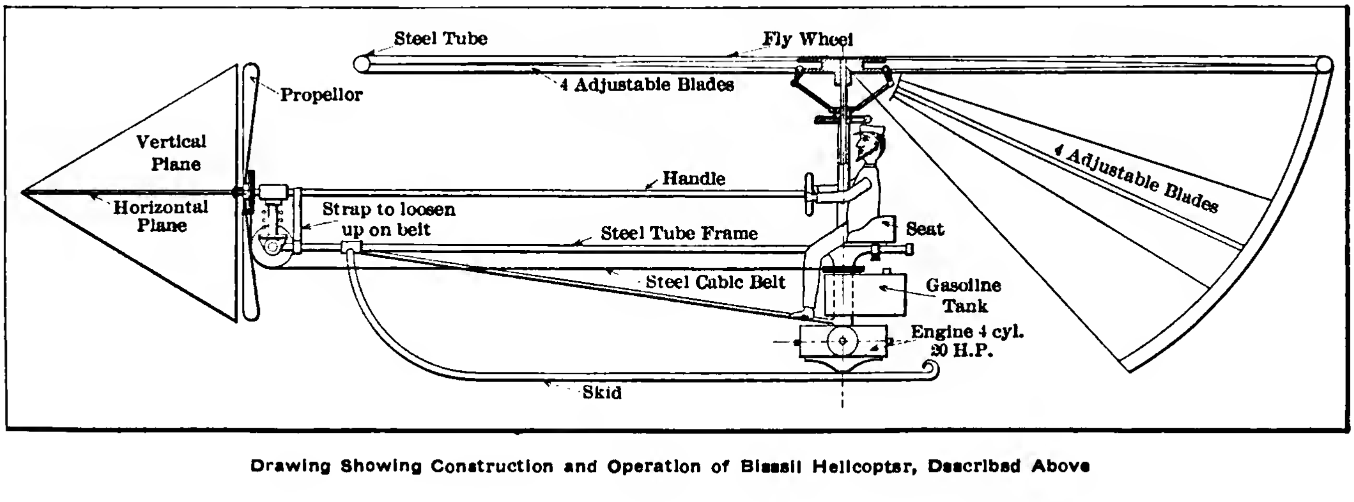
[2,145]—Will you please tell me in your columns why full elliptic springs are not in use more than they are. I had a car last year with full elliptic springs which rode very easy; this year I have a new car with semi-elliptic springs and a longer wheel-base and I feel the bumps much more. I intend changing for a new car with full elliptics unless I learn of some serious reason why they are faulty. C. F. H.

Milwaukee, Wis.

The relative advantage of full and semi-elliptic springs is one of the questions in automobile design which are still far from having reached a definite status. It seems as though a great many makers have decided to compromise on the three-quarter elliptic. You are mistaken in assuming that the difference in riding qualities in your two cars is due solely to the different types of springs. It is just as easy to make an easy-riding semi-elliptic and a hard-riding full elliptic as the reverse; and if you buy another car selected simply because it has full elliptics, you will run a good chance of being "stung" again. The difficulty is not in the type of springs, but in the proportioning of their stiffness to the weight of the car and its load.

Before going so far as to get another car, we think you had much better see what can be done to improve your present one. If the springs seem short, compared to those in use on other cars, it may be possible to arrange for longer ones. Shock absorbers, of one of the many types on the market, might do the trick, or a set of new springs of more or fewer leaves. The cost of such additions or alterations would be insignificent compared to the cost of a new car, and, if the present machine suits you in other respects, might be much more satisfactory in the end. If you will tell us the type of your car (runabout or touring), its weight, the length and width of the springs and the number and thickness of the leaves, we will be glad to advise you more definitely.

Or, it is possible that some spring maker will be glad to take the matter up with you, pointing out where the present spring suspension is defective, how it may be remedied with the least trouble and expense; also, the total expense.



Drawing Showing Construction and Operation of Bissell Helicopter, Described Above

BEST WAY TO CRANK

Editor THE AUTOMOBILE:

[2,146]—I have noticed in your issue of December 2 that C. S. J., of Paterson, N. J., is experiencing some difficulty in cranking his Lozier car, and he asks for some suggestion on how to overcome it.

I do not understand what the difficulty can be, because I own both a four-cylinder Lozier "Briarcliff" and a six-cylinder Lozier touring car, both of which I can crank with ease; and if C. S. J. will follow out my instructions, as given by the accompanying photographs, I believe he will have no further trouble.

I trust that these photographs will be of interest both to you and to your correspondent. GAYNOR KEELER.

Albany, N. Y.

The photographs, which we gladly show in the adjoining column, certainly reveal no alarming difficulties. Moreover, they illustrate, better than anything we have ever seen before, the one and only right way to crank a car. Nearly everybody knows by this time that the compression of the motor should be overcome by pulling the crank up, rather than by pushing it down. For this should the motor backfire, in the former case the crank would simply be jerked from one's fingers; while in the latter the shock would come against the rigid arm, and, if the arm should bend, the crank would be likely to hit the cranker on the jaw. The advantages of cranking left-handed are not so plain. It will be seen, however, that if after the suppositious backfire the crank should swing completely around, in the left-handed case the jerk would tend to throw the arm out of the way; whereas right-handed the arm would be thrown directly in the path of the return swing, and would receive a painful bruise, if not a broken bone. Another reason is that, owing to the direction the crank turns in, one can brace better for the upward pull when the crank is in the left hand.

Grasp Starting Crank In Left Hand;

Next, Push the Crank In;

A Pull Upward Throws the Motor Over;

Then—Listen! There She Goes

Now, No Use Arguing the Matter

LIKES STORAGE TANKS

Editor THE AUTOMOBILE:

[2,147]—Referring to the article entitled "The Private Garage Problem," by M. A. Hall (pages 1083-1086), in your December 23, '09, issue, in which Mr. Hall makes some suggestions about underground gasoline storage tanks, permit me to make some comment thereon.

While extremely valuable to the motorist of moderate means, Mr. Hall's suggestions on storage tanks are apt to be somewhat misleading to those not thoroughly familiar with the strict requirements of insurance companies and municipal ordinances as to the storage of gasoline. One of these rules, and one that is rigidly enforced, is that forbidding the storage of gasoline under pressure.

Mr. Hall's seeming preference for air pressure in forcing the gasoline out of the storage tank instead of the slow, uncertain suction pump, has the writer's heartiest approval. Of course there are some splendid double-action continuous-flow pumps on the market, but they are rather expensive, and since the idea is to cut down expense, these higher priced pumps must be eliminated.

Now for the point I wish to make. The two cocks shown in the diagram (the inlet for the air and outlet for the fluid) are all right so far as they go and permit the flow of gasoline to be stopped instantly—BUT they do not allow the compressed air left in the tank to escape, hence the gasoline in the tank remains under pressure, which is contrary to the regulations I have mentioned.

The writer has seen this defect overcome in the equipment of a one-barrel tank which he purchased from a Pittsburgh, Pa., firm. Stopping the pump stops the flow of gasoline after which a small cock (attached to the outlet pipe of the pump) is opened and permits the air to escape. The main air-cock is then closed and locked to prevent leakage or pilfering. Supplementing Mr. Hall's suggestion, I might state that the whole outfit did not cost more than the home made one would with the added assurance that it conforms absolutely to insurance and municipal requirements.

Mr. Hall's statement that a garage without this equipment loses money for its owner is borne out by comparisons of my own gasoline costs before and after the purchase of the tank. Apart from the great saving in this direction, the refilling of the car tank is no more trouble than drawing a pail of water from a water faucet, and most car owners know what that means. T. M. DAY.

Pittsburgh.

The writer above missed the point that it was possible in the design shown to open the air supply cock, allowing the air pressure to escape, when desirable or necessary.

MAGNETOS ON AEROPLANES

Editor THE AUTOMOBILE:

[2,148]—In your issue of December 23 we find a news paragraph under the caption, "Now an Aeroplane Magneto." It may be of interest to you to know that the use of "Now" in that headline is rather misleading, for several special magnetos for aeroplanes, with certain parts built of aluminum, have been made and used with success by the Bosch Magneto Company for considerably more than a year. Moreover, a magneto of power which weighs as little as 11 pounds has been among the models of Bosch magnetos for several more than 12 months.

But it must be borne in mind that in spite of some demand for magnetos of light weight for aeroplane use, there are some masters of the air who are not particular about what their magnetos weigh. On this subject Mr. Wilbur Wright, when interviewed a day or two before his historic flight up the Hudson, said "a heavy magneto which helps develop one-quarter more horsepower is all right; and I am perfectly willing to take a few more pounds handicap provided I can get the extra one-quarter horsepower." These remarks of Mr. Wright's were brought out in discussing two models of Bosch magnetos which he was using. One, a rather small magneto, was a new Bosch device with which he was experimenting.

On the subject of aeroplane ignition, you will doubtless be interested in the reports covering the ignition of the aircraft at Rheims and Brescia. From complete data and records in our hands covering these two meets we have compiled the following data:

At Rheims the four great prizes were won by Bosch equipped aeroplanes. Curtiss took the Gordon Bennett Cup and the Prix de la Vitesse; while Farman with his Gnome motor which is Bosch equipped captured the Grand Prix de La Champagne et de La Ville and the Prix des Passagers.

Of twenty contestants in these four contests the motors of eight of the aeroplanes were equipped with Bosch magnetos, seven with batteries and six with other ignition apparatus.

At the Brescia meet Curtiss won the Grand International Prize de Brescia and another minor prize; while Calderara with his (Italian) Wright Bosch-equipped biplane captured four prizes. In other words, six of the nine events were won by aeroplanes equipped with Bosch magnetos, and these contests included prizes for starting, passenger carrying, circling, high flying for the day and other special prizes for the varying lengths. The results show that the Bosch ignition was found efficient and serviceable in all sorts of contests and under greatly varying conditions.

In both of these meets it is interesting to observe that the Bosch magneto was the ignition most favored, while the use of batteries was next in popularity, but not a single prize was won by an aeroplane which depended on batteries, and of the 13 prizes of the two meets (Rheims and Brescia) 10 prizes and trophies were won by aeroplanes equipped with Bosch magnetos; the other three prizes were won by Rougier with a Voisin aeroplane with Gibaud equipment.

While what has been is of interest to every one connected with the aeroplane industry, what is going to be is of no less importance, and an illuminating side light on the enormous growth of the aeroplane industry may be gained from the fact that orders for 700 Bosch magnetos for 1910 aeroplanes have already been booked. Of course, these 700 magnetos are not for American use exclusively, but include the orders of French, German and other European aeroplane makers.

BOSCH MAGNETO COMPANY.
Per Harlow Hyde.

BY H. H. FRANKLIN, PRESIDENT, H. H. [illegible]

UNQUESTIONABLY the incoming Legislature will undertake to modify the existing motor vehicle law. There is so much interest in motor vehicles that users, manufacturers and legislators will consider that they should undertake to do something in motor vehicle legislation. What all should recognize is that the public does not need a new law, or more law, so much as it needs an enforcement of present law.

Against the operation of the present law, the great complaint is that of reckless driving and the consequent killing and maiming of innocent people upon the highways. The trouble is not that the speed restrictions are not severe enough, or that the penalties for their violation are not heavy enough, but that public officials do not exercise the power which the law gives. If a driver operates "a motor vehicle on the public highway at a rate of speed greater than is reasonable and proper, having regard to the traffic and use of the highway, or so as to endanger the life and limb of any person, or the safety of any property," he is guilty of a misdemeanor and liable to a fine of $100 for the first offense; for the second offense to a fine of $100 and 30 days' imprisonment: and for the third to a fine of $250 and 30 days.

The law goes further and says that even if the speed of the motor vehicle is safe as to the traffic of the highway and does not endanger life or property, still at street intersections, at sharp curves and on bridges, etc., the speed shall not exceed four miles per hour, and in closely built-up portions of cities and villages shall not exceed ten miles per hour, and in other portions of cities and villages shall not exceed fifteen miles per hour, while in the open country, it shall not exceed twenty miles per hour; *i. e.*, the law says *first*, that the speed must always be safe, and *second*, that, whether safe or not, it cannot exceed the prescribed limits.

However, the law does not stop with the foregoing, but says that if any city or village is dissatisfied with the above provisions, by action of its common council or board of trustees, and by posting certain specified signs, it may provide for such lesser speed as it shall desire, except that such provisions for lesser speed shall apply to all vehicles and shall not be less than ten miles per hour in incorporated villages.

Is there any dissatisfaction on the part of the public with the speed restrictions of the present law? Clearly not. If dissatisfaction existed, it would appear in the cities of the State, where motor vehicle accidents principally take place; and if it did appear in the cities, it would manifest itself in a disposition to take advantage of the provisions of the law which authorizes any city of the State to make the speed limits whatever it sees fit, provided the restrictions are made to apply to all vehicles and provided the certain specified signs are posted. So far as I know, no city of the State has taken advantage of these provisions of the statute.

Is the law too lenient as regards penalties for violating speed provisions? Clearly not. If it were too lenient we would expect to find justices of the peace and courts of special sessions giving convicted violators of the motor vehicle law the full penalties prescribed. On the other hand, it is doubtful if a case can be found in the State of New York where the punishment of the convicted offender has been as severe as the law would allow.

If the speed provisions and the penalties for their violations are as severe as they should be, clearly there is nothing further that the public needs for its protection except the enforcement of the law. Enforcing the law will stop speeding and stop accidents more than all the amendments to the existing law and more than any new law that the Legislature can enact.

THE MOTOR WISE GRASP OPPORTUNITY

Dealers must dispose of the grist. The mill is grinding out automobiles on a basis of, perhaps, 280,000 this year. There is a good automobile for every one of the possible purchasers in this vast assortment by virtue of proper selection, but in the absence of care in making the distribution there may be a number of misfits.

The motor wise among the dealers are bound to take due cognizance of the great loss which the industry must endure, if, in the distribution of the product of the year, the automobiles and the purchasers are not in harmony with each other. No automobile is good if it is not suitable for the intended work, and the dealer, in selling a car, must ascertain if the service to be rendered is that which the car is capable of.

There is just as much possibility of delivering the wrong automobile if it costs the price of a house and lot as will be true of the cheapest automobile made, and, considering the future of the industry, there is every reason why the dealer should find that class of customer who will be able to utilize his make of automobile, and that, too, to excellent advantage. If there is a buyer for every automobile made, and apparently there is, then there is absolutely no reason why dealers should employ hypnotic methods—persuading beggars to sport diamonds is bad business. The idea that the purchaser must take care of himself may be a good dictum in general, and in law, but the automobile business needs all the prestige it can get from wise and fair dealing and that it is wise to overtion to rub pollen off the sleeves of veteran engineers, which would be a logical conclusion under an arrangement of this sort.

GARDEN DELIVERED ITS QUOTA OF SUCCESS

Without attempting to analyze the statements of the officials who proclaim the show at the Garden as the greatest success of the industry; that the attendance was fully 30 per cent above that of last year, and that arrangements are now on for the proper launching of the next year's exhibition of the swollen A.L.A.M. membership (there are now 62 members), it is well within reason to point out than any of the earlier talk about abandoning shows is without the pale of a sane possibility.

The attendance, this year, was the buying kind, and this was adequately indicated by the weight of actual purchasing, not counting the possibilities and as is generally well appreciated, shows do not, as a rule, make a large number of sales on the premises. Autoists go there to see things, and to make comparisons while the opportunity affords. This year, for some reason which has not been explained, these same autoists were ready to make purchases, and that a good increase in actual sales were consummated is assured. The number of agency representatives who visited the Garden this year was far in excess of all previous showings, and that this means something to the makers of automobiles is also a matter which cannot be denied.

S. A. E. HELD SECOND HALF OF ANNUAL MEETING

NEW YORK CITY, Jan. 13—The second half of the dual annual meeting of the Society of Automobile Engineers opened at 10 o'clock a. m. at the Engineers' Society's building, with an attendance which was regarded as very satisfactory indeed, numbering in its makeup many of the most enthusiastic of the men who are responsible for the high qualities of automobiles as they obtain in America at the present time.

When the ballots were duly counted, this having been the meeting which shouldered the pleasant duty of determining as to the personnel of the officers of the society for the ensuing year, it was found that a perfect accord of the members was indicated, and the officials duly elected were made known to be as follows:

LATEST OFFICIAL MAKE-UP OF THE SOCIETY

President, H. E. Coffin; first vice-president, H. G. Chatain; second vice-president, Prof. Rola C. Carpenter; managers, H. Cunz, W. C. Wall and H. M. Donaldson; treasurer, A. H. Whiting (re-elected). Alexander Churchward is the society's secretary. This office is appointive.

According to the by-laws of the society, there are five past presidents to hold a position in the council; when the number exceeds five, one will be retired every year. As it is, considering the past presidents available, all are members of the council, they being as follows in the order of service: A. L. Riker, Thos. J. Fay, and Henry Hess, who just retired to make room for the new president.

THE FUTURE OF THE SOCIETY LOOKS BRIGHT

When the new president took the chair, after passing over purely routine matters, he entertained the members present in divers ways, among which the question of the duties of such a society were discussed. The paper, by B. D. Gray, in relation to motor tests and methods of recording them, brought out many points of more than a little merit, and Mr. Coffin, in handling this discussion, pointed out that the cost of making tests, conducting original investigations and reaching satisfactory conclusions would be very great.

It was said, among other points which were brought out, that it is highly improbable that any single manufacturing company will be likely to stand the cost of such investigations, and to illustrate just what this means an example was cited, in which it appears that one company, desiring to ascertain more information about internal combustion motors, expended the enormous sum of $100,000 without exhausting the subject from its angle.

That there are many things to be ascertained before internal combustion motors will be on a basis of finality is now assured, and, as Mr. Coffin stated, "Few, indeed, are the concerns who have had time in which to go into the matter sufficiently to feel that motors are, even now, beyond swaddling clothes."

The committee on test, under the direction of B. D. Gray, as chairman, will handle the matter from a certain point of view, rather with the hope, perhaps, that purchasers of automobiles, when they desire to ascertain if the manufacturer, in any given case, is making a delivery in accordance with the specifications, will be in a position to determine (upon a standard basis of comparison) by having a test run, just what the real status may be.

This may look to the casual observer like a simple thing to do, but when all angles are contemplated it is so extremely difficult as to hold all the elements of a first-rate problem, even under the guidance of a special skilled committee, under the auspices of the first body of engineers in America, nor has this problem been solved by any of the older bodies of automobile engineers as they exist abroad.

AFFILIATED MEMBERSHIP TO BE INSTITUTED

Last year, when the "International" grade of membership was established in the society, it was thought that about all avenues of utility from the membership point of view were closed. It has been found, however, that there is still room to expand, and the last effort in this direction is by way of an "Affiliated" member, the status of which will be gone into at a later moment.

The papers, as previously announced, were added to by a very interesting paper on the subject of transmission gears by Dr. G. W. Sargent, and, in view of another arrangement which the society has consummated in relation to the publication of papers, this paper will be given out at an early date.

The new arrangement, which is now assured, is one in which the society will spread broadcast all the facts, including discussions, as they appear in the very desirable papers which are read from time to time before the society. The new arrangement has the advantage of giving to the society an additional income, it being the cast that the principal automobile publications in America will take and pay for the matter on a fixed "minimum" basis, and, additional, on a word basis, for all above a certain minimum. The papers are of the greatest possible interest to those who have to struggle with the problems of the day, and they should prove of excellent value to autoists in general. This arrangement, then, kills three birds at one time; *i.e.*, engineers will have the information at their disposal, the society will realize an additional income, and autoists will benefit by closer contact with the engineering subjects of the day.

A BANQUET ENDED THE YEAR'S ACTIVITY

In the evening, after the business of the year was concluded, the members and guests retired to the Engineers' Club, and at 7 o'clock were seated to a "spread' which proved to be one of the most enjoyable in the history of the society. At the appropriate instant the retiring president related the incidents of his year of labor, and, as might have been expected, the experiences were of an advantageous character, giving to the society many things which it wanted, and planning for the future the remaining matters which are to make the society large, influential and of the greatest advantage to the industry.

The membership has grown steadily, and to-day, counting "live" members, the society numbers upwards of 300 engineers, besides a fine showing of associates, internationals and possibilities. The idea of a neutral society of engineers of the automobile fraternity has proven to be well founded, and it is now assured that the society will grow and prosper; this alone is a matter of relatively large importance, considering the needs of the industry, it being true that everything should be subordinated to the question of the quality of the products which come from plants. That associated engineers will be able to do better than will be possible under any other way of proceeding is too sure to require discussion, but what is more to the point, this society has already made a "dent" in the quality of the automobiles made. The following members and invited guests attended the banquet:

H. W. Alden, Detroit; Joseph A. Anglada, Brooklyn, N. Y.; Bertram Bailey, Minneapolis, Minn.; Albert C. Bergmann, New York City; E. T. Birdsall, New York City; H. H. Brown, Boston; Rolla C. Carpenter, Ithaca, N. Y.; Henry Cave, Springfield, Mass.; Alexander Churchward, New York City; Howard E. Coffin, Detroit; H. F. Donaldson, New York City; Burton G. Ellis, Medford, Mass.; Thos. J. Fay, Brooklyn, N. Y.; Peter Fogarty, New York City; D. B. Gray, Providence, R. I.; Charles F. Herreshoff, Detroit; William Hesselkus, New York City; C. B. Hayward, New York City; William Herreshoff, Bridgeport, Conn.; Henry Hess, H. L. Hess, Jr., Philadelphia; M. R. Hutchison, New York City; Lindley Hubbell, Hartford, Conn.; W. P. Kennedy, New York City; William V. Lowe, Fitchburg, Mass.; Arthur R. Mosler, New York City; George C. McMullen, Buffalo, N. Y.; A. L. McMurtry, New York City; A. F. Masury, New York City; Frank Matheson, Wilkes-Barre, Pa.; Frederick S. Newman, Chicago; A. L. Riker, Bridgeport, Conn.; C. C. Reddick, Richard F. Russell, Brooklyn, N. Y.; G. W. Sargent, Reading, Pa.; A. J. Slade, New York City; Herbert L. Towle, New York City; H. M. Swetland, New York City; Allan H. Whiting, New York City; E. R. Whitney, Philadelphia; Clarence E. Whitney, Hartford, Conn.; Frank E. Whitney, Philadelphia; S. L. Wetherill, Philadelphia; Lawrence R. Whitcomb, Boston.

Invited Guests: G. K. Bradfield, G. G. Behn, F. E. Bright, W. J. Childs, M. J. Lathrop, C. H. Taylor.

MEETING OF A. A. A. LEGISLATIVE BOARD

Eleven State associations of the American Automobile Association were represented in the session of its national legislative board, held at headquarters, 437 Fifth avenue, Wednesday of last week, and presided over by Chairman Charles Thaddeus Terry. Vermont, Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Delaware, Ohio, Colorado and Nebraska were the States that supplied delegates, and a thorough discussion of the general legislative situation occupied several hours. Much time was devoted to the Federal Registration Bill and the National Legislative Convention which will take place at Washington, D. C., February 15, 16, 17.

The sole point sought to be effected by the Federal Registration Bill, as outlined by Chairman Terry, is to afford a motor vehicle user, after he shall have obtained his license to operate from the State of his residence, to procure from the Federal bureau in Washington a Federal license which will enable him to operate without the necessity of procuring any further license, or of paying any further fees, wherever he may choose to take his car. The bill does not in any effect interfere with States rights to regulate automobiles in all other respects, as to speed, signal devices, brakes and the like, and it leaves every State free to regulate the use of motor vehicles within its borders as it may choose in all these respects.

There was a thorough discussion of the question of the special taxation of automobiles, whether under the name of registration fees or license fees. It was the sense of the meeting that on principle there was no justification for charging automobilists for the use of their cars, anything more than such sum as should be sufficient to cover the cost of registration and the issuance of identification marks. Besides Chairman Terry those present were:

Maryland—H. M. Rowe, Automobile Club of Maryland.
Massachusetts—J. P. Coghlin, Worcester Automobile Club; A. E. Lerche, Springfield Automobile Club; R. C. Cooley, Springfield Automobile Club; W. A. Thibodeau, Auto Legal Assn., Boston; Francis Hurtibus, Jr., Bay State Automobile Association.
Vermont—S. S. Ballard, Automobile Club of Vermont.
Connecticut—C. H. Gillette, Automobile Club of Hartford; H. W. Weed, Automobile Club of Bridgeport; C. M. Robinson, New Haven Automobile Club.
Pennsylvania—Powell Evans, Automobile Club of Philadelphia.
New York—H. A. Meldrum, Automobile Club of Buffalo; Howard F. Martin, Albany Automobile Club; O. A. Quayle, Albany Automobile Club; Bert Van Tuvle, Automobile Club of Rochester; J. B. McMurrich, Oswego Automobile Club; H. F. Elliott, Bronxville Automobile Club.
New Jersey—A. G. Batchelder, Summit, N. J.
Delaware—John Bancroft, Delaware Automobile Association.
Colorado—G. A. Wahlgreen, Denver Motor Club.
Nebraska—D. C. Bradford, Omaha Automobile Club.
Ohio—A. J. Pray, Columbus Automobile Club.

PROSPECTIVE LEGISLATION IN KENTUCKY

LOUISVILLE, KY., Jan. 17—Closely akin to the Wyatt-Bosworth amendment, providing for good roads, three proposed bills are to be submitted to the Kentucky General Assembly next month. One of the bills establishes the office of county road engineer and authorizes each county in the State to issue bonds to improve and build roads. The second bill creates a State department of public roads under the Commissioner of Agriculture. This will be headquarters where all contracts for road building and improvements will be drawn up and let to construction companies. The third bill provides for a fund to build and maintain roads in the State. This fund is to be established by means of a tax levy, the amount of which is to be fixed by the Legislature.

OHIO AFTER LICENSE DELINQUENTS

COLUMBUS, O., Jan. 17—By orders issued by the Ohio State Automobile Department, all cars not provided with the mahogany tag of 1910 will be held up and the drivers or owners arrested for violation of the law. A grace of ten days has been allowed for all owners to secure their 1910 tags, and a large number have failed to take advantage of the extension of time. Hereafter orders have been issued for all owners to be prosecuted. Police will see that the law is obeyed.

BRISCOE STRONG FOR GLIDDEN TROPHY

EDITOR THE AUTOMOBILE:

In view of the recommendation made by an official of the American Automobile Association relative to discarding the famous Glidden trophy and returning it to its donor, Charles J. Glidden, I take this opportunity to protest any such action by the Contest Board of the A. A. A.

I protest not only for the Maxwell concern, but for many other concerns holding membership in the Manufacturers' Contest Association and who have competed for this trophy since its presentation to the A. A. A.

To discard this classic touring trophy of the country at this time, after it has accomplished so much good for the industry, is, in my opinion, an extraordinary action and one which would be regretted not only by motor car makers but by the public as well.

Surely no automobile trophy ever competed for in this country has done so much toward the progression of the motor car industry, not excepting even the Vanderbilt Cup.

Donated in the early days, when the automobile was looked upon as the rich man's toy, it created enthusiasm throughout the territories through which the Glidden Tour was run; it showed the public in general that the motor car could accomplish all that was claimed for it; it demonstrated that the "horseless carriage" had become a permanent fixture in social and business life; it has done more than anything else to sound the death knell of the horse and its relegation to the farm; it has given manufacturers a superior opportunity to learn the strong and weak points of their cars, which could not have been learned under general touring conditions. This, in brief, is what the Glidden Trophy has done for the industry, sport and pastime, and it is this same famous classic trophy that certain interests would now bury in the historic archives of motordom!

The Glidden Tour is well known by the public at large, from Boston on the east to the Golden Gate on the west, and from the Gulf of Mexico to the Great Lakes. It is the public barometer as to what the various cars can do in endurance, mountain climbing, plunging through sand or gumbo, or speeding over macadam roads. The Glidden Tour has taken the automobiles through country hardly passable by horse vehicles, and has fully demonstrated that the motor car can accomplish what no other form of transportation can.

None of these would have been learned so rapidly if not for Mr. Glidden's generous offer in donating the famous trophy which bears his name. As a pioneer he certainly is entitled to any credit which may be his. Personally I believe that too much credit cannot be given him for his foresight and keen intuition of the benefits to be derived from an annual contest such as the Glidden Tour has developed into. I doubt if Mr. Glidden himself even dreamed what wonderful beneficial results would be accomplished for the motor car when he first donated the trophy.

To me it sounds inconsistent for this A. A. A. official to recommend the withdrawal of the Glidden Trophy and offer certificates in its place, when in the same statement he says: "At this time suitable resolution should be offered expressing the appreciation of our Association to the generous donor of the Glidden Trophy, and a committee appointed to present such resolution to Mr. Glidden, with power to arrange with him as to the disposition of this trophy. Too much credit cannot be given Mr. Charles J. Glidden for his generosity and foresight in offering this trophy which has made it possible for this tour to become an event of national importance."

In other words, the recommendation is made to withdraw the trophy when in the same breath it is conceded that in offering the trophy Mr. Glidden "has made it possible for this tour to become an event of national importance." Let us keep the trophy and continue it in the high place which it has earned.

BENJAMIN BRISCOE,
President Manufacturers' Contest Association.

A. A. A. CONTEST BOARD IS BUSY

The new contest board of the American Automobile Association is bending every effort toward the rounding out of the projected racing circuit for 1910, and it will be its endeavor to make a schedule of meets and contests in such a way as to avoid long jumps for racing teams. The middle West and South will doubtless figure prominently in the schedule. Both Atlanta and Indianapolis have speedway promoters with ambitious plans for the year. The Southern Motordrome managers figure on two or three sets of dates, while it is said that Savannah plans some sort of a successor to the grand prize race of Thanksgiving Day, 1908. Indianapolis, according to report, has applied for dates that will include Memorial Day, July 4th and Labor Day. In the East it is said that Brighton Beach will be the scene of four 24-hour races, while the Vanderbilt Cup contest has been timed to occur about the beginning of October.

A. L. A. M. NOW LICENSES SIXTY-TWO MAKES

AT a well attended meeting of the board of managers of the Association of Licensed Automobile Manufacturers January 13, with President Clifton in the chair, Col. George Pope, chairman of the show committee, in his report stated that all records had been broken by the A. L. A. M. Show at Madison Square Garden this year, the daily attendance showing an increase of 30 per cent over former years. He announced plans for housing the big A. L. A. M. membership in the Garden at the 1911 show.

Alfred Reeves was unanimously elected general manager of the association. He was formerly general manager of the American Motor Car Manufacturers' Association, a majority of the members of which have joined the A. L. A. M. Coker F. Clarkson, who has been assistant general manager of the A. L. A. M. during the past year, will continue in this position.

The American Motor Car Company, Indianapolis, Ind.; Dorris Motor Car Company, St. Louis, and Mack Bros. Motor Car Company, Allentown, Pa., were granted licenses under the Selden patent. There was a number of other applicants for licenses, but the three above mentioned were the only ones admitted.

An important feature of the meeting was the empowering of the executive committee to institute such suits against automobile manufacturers who are infringers of the Selden patent as counsel may advise. There are now 62 makes of gasoline cars licensed under Selden patent, more than one-third of these having been so licensed since Judge Hough of the United States Circuit Court broadly sustained the Selden patent as covering the modern gasoline automobile. The complete list of licensees, and the cars they manufacture, revised to January 15, is as follows:

American Locomotive Company, Alco; American Motor Car Company, American; Apperson Bros. Automobile Company, Apperson; Autocar Company; Autocar; Bartholomew Company, Glide; Brush Runabout Company, Brush; Buckeye Manufacturing Company, Lambert; Buick Motor Company, Buick; Cadillac Motor Car Company, Cadillac; Chalmers-Detroit Motor Company, Chalmers-Detroit; Corbin Motor Vehicle Corporation, Corbin; Columbia Motor Car Company, Columbia; Dayton Motor Car Company, Stoddard-Dayton; Dorris Motor Car Company, Dorris; Elmore Manufacturing Company, Elmore; Everitt-Metzger-Flanders Company, Studebaker E-M-F, Studebaker-Flanders; H. H. Franklin Manufacturing Company, Franklin; Haynes Automobile Company, Haynes; Hewitt Motor Company, Hewitt Truck, Everitt; Hudson Motor Car Company, Hudson; Hupp Motor Car Company, Hupmobile; Jackson Automobile Company, Jackson; Knox Automobile Company, Knox; Locomobile Company of America, Locomobile; Lozier Motor Company, Lozier; Mack Bros. Motor Car Company, Mack Truck; Matheson Motor Car Company, Matheson; Maxwell-Briscoe Motor Company, Maxwell; Mercer Automobile Company, Mercer; Mitchell Motor Car Company, Mitchell; Moline Automobile Company, Moline; Moon Motor Car Company, Moon; Mora Company, Mora; National Motor Vehicle Company, National; Nordyke and Marmon Company, Marmon; Olds Motor Works, Oldsmobile; Packard Motor Car Company, Packard; Palmer & Singer Mfg. Co., Palmer-Singer; Peerless Motor Car Company, Peerless; Pierce-Arrow Motor Car Company, Pierce-Arrow; Pierce Motor Company, Pierce-Racine; Pope Manufacturing Company, Pope-Hartford; Premier Motor Manufacturing Company, Premier; Regal Motor Car Company, Regal; Reo Motor Car Company, Reo; Royal Tourist Car Company, Royal Tourist; Alden Sampson, 2d, Sampson Truck; Selden Motor Vehicle Company, Selden; Simplex Automobile Company, Simplex; F. B. Stearns Company, Stearns; Stevens-Duryea Company, Stevens-Duryea; Studebaker Automobile Company, Studebaker-Garford; E. R. Thomas Motor Company, Thomas; Waltham Manufacturing Company, White; Willys-Overland Company, Overland, Marion; Winton Motor Carriage Company, Winton; York Motor Car Company, Pullman.

The following were in attendance at the meeting:

James Joyce, American Locomotive Company; George H. Strout, Apperson Bros. Automobile Company; John S. Clarke, D. S. Ludlum, Autocar Company; A. Y. Bartholomew, Bartholomew Company; Frank Briscoe, Brush Runabout Company; W. C. Durant, Buick Motor Company; W. C. Leland, Cadillac Motor Car Company; Hugh Chalmers, Chalmers-Detroit Motor Company; Herbert Lloyd, H. W. Nuckols, Columbia Motor Car Company; M. S. Hart, Corbin Motor Vehicle Corp.; Wm. R. Innis, Everitt-Metzger-Flanders Company; G. H. Stilwell, H. H. Franklin Mfg. Company; Elwood Haynes, Haynes Automobile Company; E. R. Hewitt, Wm. E. Metzger, Hewitt Motor Company; R. D. Chapin, Hudson Motor Car Company; G. A. Matthews, Charles Lewis, Jackson Automobile Company; A. N. Mayo, Knox Automobile Company; S. T. Davis, Jr., A. W. Robinson, Locomobile Company of America; H. A. Lozier, Lozier Motor Company; F. F. Matheson, Matheson Motor Car Company; Benjamin Briscoe, Maxwell-Briscoe Motor Campany; Wm. T. White, Mercer Automobile Company; Henry Plow, Mitchell Motor Car Company; W. H. Van Dervoort, Moline Automobile Company; C. C. Hanch, Nordyke & Marmon Company; H. B. Joy, Packard Motor Car Company; L. H. Kittredge, Peerless Motor Car Company; Charles Clifton, Pierce-Arrow Motor Car Company; George Pope, A. L. Pope, Pope Mfg. Company; H. O. Smith, Premier Motor Mfg. Company; R. E. Olds, Reo Motor Car Company; Geo. J. Dunham, Royal-Tourist Car Company; G. E. Mitchell, Alden Sampson, 2nd, R. H. Salmons, George B. Selden, Selden Motor Vehicle Company; F. B. Stearns, F. B. Stearns Company; Wm. R. Innis, Studebaker Automobile Company; E. R. Thomas, E. R. Thomas Motor Company; Windsor T. White, Waltham Mfg. Company; Thos. Henderson, Winton Motor Carriage Company; Thos. C. O'Connor, York Motor Car Company.

SUCCESS OF THE PALACE SHOW

At the meeting of the committee of management, American Motor Car Manufacturers' Association, held at the New York headquarters last week, R. E. Olds, chairman of the show committee, rendered his report of the Grand Central Palace show, indicating that the affair exceeded in attendance, in the amount of business done and in profits any previous automobile exhibition held at the Palace. A dividend of 72 per cent. on the amount paid for space was declared to the Importers' Automobile Salon and the Motor and Accessory Manufacturers, who were interested in the show with the organization of makers.

A letter was approved to be sent to every member of the association relative to the annual meeting to be held in Chicago on February 9, for action on the association's agreement which expires by limitation on that date. The clause reads as follows:

The term of this agreement is for five years, but any party hereto shall be considered as withdrawn from the terms hereof who fails to pay the sum or sums hereinafter mentioned within thirty days of demand therefor by the committee heretofore created.

Upon motion, duly seconded, the resignation of Alfred Reeves as general manager, was accepted with regrets.

It was voted by the association to present R. E. Olds, chairman of the 1910 show committee, a suitable token in appreciation of his leadership in connection with the show.

At the meeting were H. O. Smith, chairman, Premier Motor Manufacturing Company; W. H. Van Dervoort, Moline Automobile Company; R. E. Olds, Reo Motor Car Company; Charles Lewis, Jackson Automobile Company; Benjamin Briscoe, Maxwell-Briscoe Motor Car Company; Henry Plow, Mitchell Motor Car Company; C. C. Hanch, Nordyke & Marmon Company; S. H. Mora, Mora Company, and Alfred Reeves, general manager.

LICENSED DEALERS TO ORGANIZE

A call has been issued with a view to forming an organization to be known as the "Licensed Automobile Dealers of New York." The meeting will be held at the Hotel Astor, Thursday, January 20, at 2 o'clock. The call is signd by the Sidney B. Bowman Automobile Company (Apperson and Marmon cars), The White Company (White cars), Geo. C. John (E. M. F. and Flanders), Oldsmobile Company of New York, General John T. Cutting (Oldsmobile), E. R. Thomas Motor Company (Thomas), Maxwell-Briscoe Company, Inc. (Maxwell), Carl H. Page & Co. (Chalmers-Detroit), R. M. Owen & Co. (Reo and Premier).

It is understood that the formation of the proposed Licensed Automobile Dealers of New York is the forerunner of similar associations in all of the big cities of the country.

MITCHELL COMPANIES ARE CONSOLIDATED

RACINE, WIS., Jan. 15—The Mitchell Motor Car Company and the Mitchell & Lewis Company, which manufactures farm wagons and buggies, were united yesterday in a new company capitalized at $10,000,000, to be known as the Mitchell-Lewis Motor Company. The new concern will be headed by William Mitchell Lewis, son of William T. Lewis, who has heretofore been at the head of both concerns.

William T. Lewis will retire from active work, but will remain in an advisory capacity as charman of the board of directors. The officers of the new Mitchell-Lewis Motor Company are: William Mitchell Lewis, president; Henry G. Mitchell, vice-president; George B. Wilson, second vice-president; Frank L. Mitchell, treasurer; G. Vernon Rogers, secretary; John W. Bate, designer and superintendent, and James W. Gilson, sales manager.

Contestants in the French Reliability Trials for Voiturettes, Climbing the Grade at St. Germain

HIGH PERCENTAGE OF CLEAN SCORES IN FRENCH TRIALS

PARIS, Dec. 28—Sixteen out of twenty-nine have survived with perfect scores in the first reliability trials held in France. The event was an endurance test of 2,000 miles spread over fifteen consecutive days, with conditions similar to those of the sealed bonnet tests of America, with the exception that the seals were replaced by an official observer. As the French observer is too often lacking in seriousness, and can be accused of such crimes as leaving his car to go shopping or sight-seeing en route, it has been decided to replace him by seals on the bonnets when the time comes for holding the next competition.

The percentage of clean score survivors is remarkable when it is considered that the event was run in midwinter over roads which were bad under the French standard. It is true there was never much mud plugging, but always a hard surface so full of pot holes that it had a masterly power of shaking nuts loose and causing the rupture of sundry bolts. As an example of the progress that has been made, it is worth recalling that in a similar event two years ago, over a good road guarded by military, there was an elimination of 50 per cent. after six days' running. This year about 35 per cent. have disappeared after fifteen days on the open road. Next year the average speed will be raised from 15 1-2 miles an hour to 19; the daily runs will be made longer, and not even the opportunity will be given to clean fouled spark plugs.

Although officially known as voiturettes, it needs a stretch of the imagination to place some of the competitors in this class. Light racing cars would be a more correct definition. Cylinder dimensions were fixed at 4.9 by 5.9 maximum bore and stroke for a one lunger; 3.9 by 5.1 for two cylinders and 3.1 by 4.7 for four cylinders. A considerable amount of speed can be got out of four cylinders of over 3-inch bore and nearly 5-inch stroke, as was fully proved during the trials. Officially, however, the extra speed above 15 1-2 miles went for nothing.

With one or two exceptions the competing vehicles were light sporting cars, many of them capable of doing 50 miles an hour on the open. Under the rules they had to be equipped for winter travel, complete with mud guards, hood, wind shield, lanterns, etc., and have comfortable touring bodies. One of the competitors went to the extent of furnishing a comfortable inside steering body, although the majority had the smallest wind shields and the lowest hoods possible, their drivers considering speed of far more importance than comfort.

Single cylinders were not as numerous as might have been expected, there being but three of this type in the sixteen clean-score winners. There were no two-cylinder cars, but plenty of small fours. The distinctive feature of the motors was the proportion of long strokes. Among the singles the dimensions in one case were 120 by 140, and in all others 100 by 130 millimeters. In the four-cylinder class the greatest proportion of stroke to bore was 1.84, and the lowest 1.38, the average being about 1.50. In the majority of cases the fours had their cylinders in one casting without a central bearing. High-tension ignition was used invariably, without any storage batteries as a stand-by.

In every case failures were due to careless driving or minor defects. George Sizaire, the one-lunger expert and speed champion, was put out of business by the breakage of a ball in a front wheel bearing. One of the four-cylinder Rolland-Pilain vehicles —the most racy looking and speediest of the whole lot—had to pull up sharp when going at 40 miles an hour. The result was a quick skid and an equally quick smashing of a rear wheel. Phil De Marne played at racing with his four-cylinder Gregoire until a back spring failed him when taking a gully at high speed. He changed the leaf alone in half an hour, but henceworth was counted among the out-and-outers. A Sizaire-Naudin went out through a valve sticking in its guide. A Hurtu broke its gasoline pipe; a Barre jumped its fan belt, and another car from the same factory damaged its radiator in a collision; a Doriot-Flandrin had a leaky radiator; a Corre-La Licorne bought bad gasoline on the road and lost so much time getting rid of it that it was not worth starting again; a friction-driven Turicum had to tighten up nuts on its friction disc; the driver of a similar type of car made by Fouillaron loitered so much that he came in beyond his time limit; a Doriot-Flandrin driver became weary of changing tires, and a Zenith car sneaked home without saying good-bye to anybody.

Those that came through after making all controls on time, without changing a part and without adjustments, represented eleven firms. Alcyon was the only one to put in three cars and bring all three through with perfect scores. Delage and Demeester started with only one each and finished perfect; all the others lost one or two cars. The perfect scorers are:

Alcyon (3) four cylinders, 2.9 by 4.3 bore and stroke.
Delage, four cylinders, 2.9 by 4.7 bore and stroke.
Demeester, four cylinders, 2.9 by 4.3 bore and stroke.
Gregoire (2), four cylinders, 3.1 by 4.3 bore and stroke.
Rolland-Pilain (2), four cylinders, 3.1 by 4.3 bore and stroke.
Corre-La Licorne (2), four cylinders of 2.4 by 3.9 and 3.1 by 4.3 bore and stroke.
Sizaire-Naudin, single cylinder, 4.7 by 5.5 bore and stroke.
Hurtu, single cylinder, 3.9 by 4.3 bore and stroke.
Barre, four cylinders, 2.9 by 4.7 bore and stroke.
Doriot-Flandrin, single cylinder, 3.9 by 5.1 bore and stroke.
Turicum, four cylinders, 2.9 by 4.3 bore and stroke.

FRENCH COMMERCIAL TRIAL RESULTS

PARIS, Jan. 12—Improvements in wheels, rubber tires and suspension are the strongest features of the commercial vehicles taking part in the recent French trials, and lubrication is the weakest, according to the technical report just issued by the judges. Of the 22 disqualified vehicles three only were thrown out by reason of accidents to wheels and tires, and of these three, one had a special type of tire being tested for the first time. Steel tires were not obligatory except under the military rules, and were not very generally employed. Their defect was a certain amount of skidding on the greasy Belgian block, and a tendency to flatten out under the continued action of the road. Shock absorbers were used extensively in conjunction with solid rubber tires, and proved most satisfactory. As the chassis in most cases is a lighter construction than a few years ago, it was possible to lengthen the springs considerably, while diminishing their width, with very good results. The improved suspension not only gave a longer life to the wheels, but was most advantageous to the mechanical organs, which in this competition finished in better condition than ever before.

The official report has not so much praise for the lubricating systems, so far as their economy is concerned. "One truck, weighing 5 3-4 tons, used 1 3-10 gallons of lubricating oil and 24 pounds of grease for a distance of 1,500 miles, while another vehicle, weighing a few pounds more, passed over the same route and used 30 gallons of oil and 15 pounds of grease; a third, weighing a few pounds less than the first vehicle, but covering a distance of 1,800 miles, consumed 66 gallons of lubricating oil and 42-5 pounds of grease. With such examples it would be most difficult to average the oil consumption of trucks."

Progress has been made in the use of various fuels by the internal combustion motor, but, in the opinion of the jury, it is desirable that the theoretical compression of the motor should be established with a full knowledge of the fuel that is about to be employed. "If the compression had been made higher the consumption of 50 per cent carburetted alcohol, which is at present equal to that of gasoline, would doubtless have been better than with this fuel. Benzol being fixed as a fuel by reason of its low price, constructors did not hesitate to modify their cooling arrangements, and to adequately warm their carburcters in order to get the most economical results.

The causes of the 22 failures out of the 54 vehicles starting in the competition are set forth in the official report. The Schneider Company had a vehicle in the ditch for 2 hours 20 minutes, and arrived late at the control; a second vehicle was disqualified by reason of magneto trouble. Krieger lost three vehicles, one by reason of ignition and carbureter trouble, a second by the loss of a rear tire, and the third by a serious leak in the gasoline tank. Panhard had a seized piston on one truck, a breakdown of the water circulating system on another, and a cracked cylinder on a third, following the breakdown of the water circulating system. Berliet figured for two vehicles in the failure class by reason of one running backwards on a hill, owing to oil on the brakes, and colliding with a following vehicle. Malicet & Blin also ran back on a hill and collided with a tree. Delaugere & Clayette burned out the anti-friction metal in a connecting rod, lost a tire, and had to change a spring hanger.

A two-cylinder Cohendet went into the ditch, but got out in time to qualify for the military portion of the trial. De Dion-Bouton had a single-cylinder delivery van which went out of business with its only cylinder cracked; a four-ton truck from the same factory broke its differential. Peugeot suffered a seized connecting rod bearing, and in another case lost a vehicle in a collision. Dietrich had two losses, one from magneto breakdown and the other by late arrival. An Aries had to be towed up a hill owing to the gears not working.

One of the Alcyon Voiturettes That Made a Perfect Score in the Recent French Reliability Trials

THE NEW LOS ANGELES MOTORDROME

Considerable interest is shown in the proposed construction of a one-mile board track at Santa Monica, a suburb of Los Angeles, Cal. Definite announcement of the plans has been made by F. E. Moskovies, the head of the enterprise, and an engineer of note. The project was quickly financed, a California railroad company assuming one-half of the stock, while the other half was immediately taken up by individuals.

Positive dates have been set for the opening meet and a sanction granted by the Contest Board of the A. A. A.—the first sanction to be granted under the new working agreement between that body and the Manufacturers' Contest Association. Seven days, April 8-9-10 and 13-15-16 and 17 are the dates selected.

In principle, this innovation will greatly resemble a bicycle track. It will cover one mile in a perfect circle, the turns having an enormous radius, even greater than that of the famous Brooklands track in England. The width will be 75 feet, the whole uniformly banked to a gradient of three in one, and 25 feet high on the outer edge. The track proper will be constructed of "two by fours" of Oregon pine properly planed down and finished in a way to insure the greatest smoothness.

A notable feature of the Los Angeles Motordrome, as it will be known, lies in the fact that owing to peculiar construction it will be completely closed against the non-paying public by its outer rim. The grand stand will encircle a certain portion of the track, having its main floor on a level with the top of the 25 foot outer edge. This grand stand will extend quite a distance around the track with entrances at various points on the ground. Its projectors claim that through its novel construction racing risk will be reduced, and greater speed made possible, and while there has been much discussion among experts relative to the merits of board surface for racing, yet some of the best engineers and drivers in the country have fallen in readily with the idea.

NEW ORLEANS READY FOR MARDI GRAS

New Orleans, Jan. 17—The New Orleans Automobile Club has been working upon its annual Mardi Gras Speed Carnival plans, and announcement has been made by the director of contests, Homer George, of the various events of the meet. Already entries have been received from George Robertson, with a Simplex; Ralph De Palma, with the Fiat Cyclone; Barney Oldfield, with his Benz, and Ben Kirscher, with a Darracq. The Jackson and Cole factories have named two cars each.

The list of events for the two days calls for fourteen races, for all classes of cars from the stock chassis of 161 to 230 piston displacement, to the free-for-alls. Three big amateur events are on the list, each with a $500 trophy. These have attracted entries so far representing New Orleans, Chicago, Atlanta, St. Louis and New York. Others are assured. Two of the events are at five miles and one at ten.

Two free-for-all races are carded each day, and one handicap. The feature of the first day is the New Oreans Hotel Sweepstakes at twenty-five miles, open to cars of A. A. A. classes 1, 2 and 4, with $250 in cash to the winner, donated by the Grunewald, St Charles, Montleone, New Denechaud and Cosmopolitan hotels. The second day's feature is the Crescent City Motor Derby at fifty miles, for the same class of stock chassis, with $250 in cash to the winner, donated by the New Orleans Progressive Union. A purse of $250 cash has been donated by New Orleans dealers to be divided among the three drivers scoring the greatest number of points in two days.

BUFFALO TO HAVE AERO SHOW

Buffalo, N. Y., Jan. 17—The Aero Club of Buffalo is making arrangements for a contest of aeroplane models to be held in one of the largest halls in the city about March 1. President John M. Satterfield will contribute a silver trophy. The club's total membership is now 61.

ANOTHER CHAPTER OF DETROIT GOSSIP

Detroit, Jan. 17.—Official announcement is made that the Lozier Automobile Company will remove to Detroit, negotiations which have been under way for some time having proved successful. Several prominent Detroiters are interested in the undertaking, and it is understood the company name will be changed to the Lozier-Detroit, following a practice prevailing among a number of local auto makers of incorporating the city name. This will add still another high grade concern to the already long list of automobile factories located here.

The Watt Motor Company, organized last November, has increased its capital stock from $100,000 to $300,000, the increase, it is announced, being occasioned by demands for the stock. A large factory will be erected in the spring.

The Ford Motor Company is now installed in its immense plant in Highland Park, just north of the city, where it will have a daily capacity of two hundred complete cars. This effectually serves to quiet rumors circulated for months, supposedly originated by disgruntled contractors, that the main building, 75 x 862 feet and four stories in height, was unsafe and would be torn down. A machine shop 840 x 140 feet, one story high, has just been completed and many more immense buildings will be constructed at once.

The Lotz Auto Company has been incoporated with a capital stock of $300,000, one-third of which is paid in. The principal stockholders are John A. Lotz, a local real estate man; Joseph Christian, Chicago; John McQueen, George Cooley and Arthur A. Fletcher. The company will manufacture a runabout and four and six-cylinder cars, the prices ranging from $600 to $1,500. It will also produce a new rubber tire, the invention of George Cooley, of Grand Rapids. A factory will be erected.

The Oriental-Detroit Company, an automobile manufacturing concern headed by O. F. Mead, of this city, and capitalized at $100,000, has secured a tract of land in Birmingham, just outside of Detroit, and will erect a factory for the manufacture of a high-powered two-passenger roadster to be marketed at a nominal price, as well as several other types of cars.

Further evidence of prosperity is found in the purchase by the Chalmers-Detroit Motor Company of another five and one-half acres of land adjoining its present plant on the east, and on which it is the intention to soon erect another addition to its already enormous plant. The company has just completed a four-story building which added one third to its factory space, making 500,000 square feet that are now available.

NEW HEIGHT RECORD AT LOS ANGELES

Los Angeles, Cal., Jan. 17—The principal event of the week of aviation trials was the new height record established last Wednesday by Louis Paulhan on a Farman biplane. The altitude was figured as 4,165 feet, and as it has been confirmed by the International Aeronautical Federation, which at the time was in session at Paris, it will stand as the official record. The best previous performance was Latham's 3,444 feet, at Mourmelon, France, January 7.

Paulhan again got into the limelight Friday, making a cross-country dash of twenty miles and return from the aviation field to San Pedro harbor, where he rounded the wireless telegraph mast. On the same day Curtiss set a record of 2:12 for the one-and-a-half-mile course. To-day Paulhan went after the distance record, but after covering 75.6 miles in 1 hour 58 minutes 27 2-5 seconds descended because of a leak in his gasoline tank. Curtiss made ten laps of the course in 23 minutes 4 2-5 seconds. Paulhan's best time in this event was 25 minutes 5 1-5 seconds.

Los Angeles, Cal., Jan. 18—Louis Paulhan again distinguished himself by a remarkable cross-country flight. Flying both with and against a wind that kept the other aviators down, he went from Aviation Field to "Lucky" Baldwin's ranch, 23 miles away, and returned to his tent, in 1 hr. 2 min. 42 4-5 sec.

What Clubs are doing these Winter Days

CAPITAL CITY CLUB ELECTS A NEWS LATE

Washington, D. C., Jan. 17—The sixth annual meeting of the Automobile Club of Washington was held to-night, and the following officers were elected for the ensuing year: President, H. Chadwick Hunter; vice-president, John K. Heyl; secretary-treasurer, Elliott P. Hough; captain, Joseph H. Falconer; lieutenant, D. J. Dunigan; governors, L. A. Dent, W. D. West, W. S. Duvall and W. H. Smith. This is an entire new slate with the exception of John K. Heyl, who was advanced from secretary to vice-president. An amendment to the by-laws was adopted in order to consolidate the office of secretary and treasurer. The retiring president, W. D. West, submitted a report which showed the club had been instrumental in securing a number of concessions for automobilists. Fifty-five new members were admitted during the year. The new president, Mr. Hunter, is one of Washington's pioneer automobilists and has been identified with every movement of interest to the motoring fraternity. He is also an authority on aviation.

BETTER ROADS BELOW MASON AND DIXON'S LINE

Baltimore, Jan. 17—The residents of Baltimore county, headed by the Good Roads Association of that section, are after improved crossroads, and have asked the Automobile Club of Maryland to help them in their efforts. The plan of the countyites is in the shape of a bill providing for a $1,500,000 bond issue, from which amount $100,000 is to be given to each of the 15 districts, to be expended in five years on improved crossroads, as the State has appropriated ample money for the turnpikes. The bill further provides that the money shall be handled by the commissioners of Baltimore county, and that the highways commission shall be composed of three county commissioners, the county roads engineer, and two other members selected by the judges of the Circuit Court for Baltimore county. The bill will be placed before the General Assembly, now in session. Members of the automobile club will put the plan before the directors at the next meeting.

BEEFSTEAK DINNER TO CHRISTEN CLUB HOUSE

Louisville, Ky., Jan. 17.—Right royally was the new clubroom of the Louisville Automobile Club christened Thursday evening. The occasion was announced as the club's "first beefsteak dinner," and it was probably the most unique event in the history of the organization. The business meeting began at 8 o'clock, at which certain changes in the by-laws and constitution were considered, with a view to making them conform to present day conditions, surrounding the sport of automobiling. Under the leadership of President Eugene Straus, the membership of the club has been increased until it now includes nearly every owner in the city. When an effort was made to exclude dealers from active membership it was promptly voted down. The club and the dealers are now in closer touch than at any previous time.

After the supper President Straus was presented with a handsome loving cup.

HARRISBURG, PA., NOMINATES FOR ELECTIONS

Harrisburg, Pa., Jan. 17—At the nomination meeting of the Automobile Club in the Metropolitan Hotel the following were put up for election next month: For president, W. O. Hickok, 3d; first vice-president, Frank H. Bomgardner; second vice-president, David G. Bowman; third vice-president, Dr. John Oenslager; treasurer, John C. Nissley; secretary, J. Clyde Myton. For the board of governors, Frank J. Brady, O. C. Robertson and H. C. Wright were nominated, to succeed C. G. Nissley, Roy W. Senseman and Dr. John Oenslager.

SYRACUSE OFFICERS RE-ELECTED FOR 1910

Syracuse, N. Y., Jan. 17.—The annual meeting of The Automobile Club of Syracuse was held at the Yates Tuesday night of last week. Hulburt W. Smith was re-elected president, and all the other officers and directors were re-elected. Annual reports by President Smith and Secretary Forman Wilkinson showed large gains in membership and finances during the year. With five new members elected that night, the club closed the year with a total membership of 410, of which 373 are resident and 37 out-of-town members.

During the year over 500 tourists have been routed from place to place at the club office, of which number 206 registered. More than 600 road signs giving warning of dangerous crossings, bad hills, sharp turns, etc., were placed along the main roads leading in and out of the city.

The club endorsed a plan to lay out a new State road from Cortland to Binghamton, and drafted recommendations to the State Highway Commission regarding improvements to roads hereabouts.

HARTFORD, CONN., CLUB INAUGURATES NEW YEAR

Hartford, Conn., Jan. 17—The first meeting of the local automobile club for the new year was held in the clubrooms on Allyn street Tuesday evening, and was purely a social session. No report on the "all-Connecticut" endurance run was submitted, but one is expected shortly. There was an informal discussion of the subject, and it was evident that there is considerable interest in the proposed event.

Refreshments were served, and everybody had a good time in the cozy quarters. The club membership continues to increase, and includes practically all the representative automobilists of the city.

QUAKER LADIES HOLD A BANQUET, TOO

Philadelphia, Jan. 17—The Ladies' Quaker City Motor Club held its annual banquet last week in the clubrooms at the Hotel Majestic. Gold and white, the club colors, were prominent in the decorations, and were repeated in the handsomely designed menu cards. During the affair a cable message was received announcing the election of the L. Q. C. M. C. to associate membership in the Royal Automobile Club of London. The committee in charge was composed of Mrs. Edward B. Finck, Mrs. Joseph J. Martin, Sr., Mrs. Joseph J. Martin, Jr., Mrs. Samuel E. Baily, Mrs. Charles Snyder and Dr. Katherine Sweeney.

BISON CITY'S AUTOMOBILE CLUB WILL BUILD

Buffalo, Jan. 17.—The board of directors of the Automobile Club of Buffalo has decided to build or buy quarters for a country clubhouse, the location of which will be within 20 miles of the city. It is planned to have the house ready for occupancy by July 1, and it will be located upon one of the principal automobile routes leading from the city. The building committee numbers 24 of the most prominent and wealthy members of the club, and is headed by Vice-President Harry Thorp Vars.

NORRISTOWN, PA., CLUB HAS 150 AT BANQUET

Norristown, Pa., Jan. 17—The Norristown Automobile Club held its annual banquet at the Jeffersonville clubhouse last Saturday night. One hundred and fifty members and guests were present, among the latter being numerous legislators, the county commissioners, State Highway Commissioner Joseph W. Hunter and representatives from all the nearby automobile clubs. Theodore L. Bean was toastmaster.

THE STUDEBAKER-E-M-F IMBROOLIO

Detroit, Jan. 18—Charges and counter charges continue to fly back and forth in the Studebaker-E-M-F controversy, which was scheduled for trial before Judge Swan, in the United States circuit court to-day, and which because of the disclosures made by both parties to the suit holds the center of the stage.

When the injunction proceedings came up to-day before Judge Swan, the attorneys for the Studebaker Company asked for a postponement of the case, owing to the fact that John S. Miller, its principal counsel, was also counsel for John R. Walsh, the convicted Chicago banker, representing him in mandamus proceedings. The E-M-F attorneys acquiesced in the request, and it was finally decided to have the hearing January 25.

When Judge Warrington, at Cincinnati, declined to have anything to do with the case, sending it back to the local United States Circuit Court, where the first action was taken by the Studebaker Automobile Company, E-M-F attorneys immediately filed an answer to the bill of complaint, in which some interesting facts are contained.

After going in detail into the business relations existing between the two companies prior to the ruction, showing how the factories were enlarged to supply the Studebaker Company with additional cars for which it was to be sole distributor, affidavits from majority stockholders in the E-M-F Company are presented to show that the schedule of cars called for by the Studebaker Company was arranged and passed upon by all the directors, and that F. S. Fish, chairman of the Studebaker Automobile Company, referring to the schedule of 15,200 cars for the first year, assured the E-M-F officials that the schedules so carefully prepared would be adhered to; that the Studebaker Company had every reason to believe the E-M-F Company would not be able to build cars as fast as the Studebakers could sell them; and that if through any unforseen cause the South Bend concern was unable to market the cars enumerated in that schedule by months it would arrange to take and pay for the cars and store them until they could be sold.

That the rescinding of this selling agreement by the E-M-F Company because of the alleged failure of the Studebaker Company to live up to the terms was welcomed by agents throughout the country it is endeavored to show through a printed volume of letters from agents who declare they were unfairly dealt with by the Studebakers in the matter of discounts, and that in order to handle E-M-F cars they were forced to purchase another car made by the Studebaker Company which they could not sell. As indicating what the rescinding of the agreement means to the E-M-F Company figures are submitted showing that by selling direct to dealers the company will take in an additional million dollars in profits and yet give the dealers fifty per cent. larger discounts than were allowed by the Studebaker Company.

Meanwhile the Studebaker Company has not been idle, last Saturday morning filing ten and one-half pounds of affidavits in the U. S. circuit court. The list comprises some one hundred and seventy-five separate affidavits from Studebaker agents all over the country, one of the chief points made being that they had rather work for the straight low discount offered by the Studebaker Company and have the prestige of that concern back of them than get the higher rate offered by the E-M-F. It was also declared that through the widespread publicity it has given the matter of discounts the E-M-F Company is demoralizing the automobile trade, rival agents being apprised of the discounts offered and other trade secrets, and being thus able to undersell.

The Studebaker Company charges indirectly that the E-M-F Company long contemplated a break, and seized upon the first excuse to cancel the selling agreement.

These affidavits, as well as providing interesting reading alike for the trade and the general public, are of value as outlining the lines along which the battle will be fought by both parties to the suit. Every point will be bitterly contested, and whichever party proves victor the case will go down in the annals of the automobile industry as one of the most expensive bits of litigation ever indulged in.

PACKARD DEALERS AT INFORMAL DINNER

Dealers in Packard cars who attended the Madison Square Garden Show were dined by the Packard Motor Car Company last Wednesday evening. The entertainment was given in the small ballroom at the Hotel Astor, and was informal in character, story telling taking the place of the usual set speeches. After the dinner courses had been served the room was darkened and an hour was given to the recital of an automobile story called "On the Road to Anywhere," illustrated by stereopticon pictures and enlivened by instrumental music and songs. The party included the following:

H. B. Joy, S. D. Waldon and C. J. Moore, of the Packard Motor Car Company; M. J. Budlong, New York; Alvan T. Fuller, A. Measure, L. R. Mack, F. C. Graves and I. H. Bolen, Boston; J. W. Tarbill, C. C. Blackmore and J. M. Richardson, Cincinnati; R. J. W. Hammill, Baltimore; C. M. Lines, Cleveland; E. C. Johnson, Philadelphia; W. N. Murray and H. P. Johnson, Pittsburg; Elliott Flint, George Cokely, Providence, R. I.; J. J. Mandery, Rochester, N. Y.; H. E. Greene, H. T. Warmick, Amsterdam, N. Y.; C. J. Bousfield, Bay City, Mich.; R. W. Whipple, Binghamton, N. Y.; W. R. Densmore, Buffalo, N. Y.; F. E. Avery, Columbus, O.; F. L. MacFarland, Denver; A. E. Barker, Detroit; C. G. Embleton, Hartford, Conn.; A. H. Dorscy, Memphis, Tenn.; F. B. Willis, Indianapolis; C. G. Welch, Milwaukee, Wis.; E. P. Moriarty, Kansas City, Mo.; G. M. Reddick, Denise Barkalow, Omaha, Neb.; Ginder Abbott, New Orleans, La.; E. C. Anthony, Los Angeles, Cal.; J. Schaitt, W. E. Seeley, Bridgeport, Conn.; J. A. P. Ketchum, H. G. Ketchum, Saratoga Springs, N. Y.; T. A. Bryson, Savannah, Ga.; C. H. Goss, St. Johnsbury, Ga.; O. L. Halsey, St. Louis; C. A. Benjamin, Syracuse, N. Y.; A. M. Thompson, Toronto, Can.; C. B. Rice, Utica, N. Y.; S. A. Luttrell, J. A. Muelheisen, Washington, D. C.; C. P. Joy, St. Paul, Minn.; C. E. Jones, H. M. Allison, Chicago; C. A. Fitzgerald, Newark, N. J.; Russell Huff, C. A. Du Charme, E. P. Chalfant, F. R. Humpage, W. L. Gleason, Allan Loomis, J. J. Ramsay, H. H. Hills, J. F. Baines, H. E. Stowell, W. H. Workman, L. W. Conkling, Detroit; E. B. Jackson, A. E. Corbin, C. W. Doty, New York.

GET DRAWBACK ON EXPORTED TIRES

Akron, O., Jan. 17—A ruling which interests the tire manufacturers of this city has been obtained from the Treasury Department at Washington, D. C., on the exportation of automobile tires. The shipment in question was made by the B. F. Goodrich Company, and the claim was that imported leather washers and steel rivets or studs had been used in the tires. The drawback allowed will equal the duty paid on the imported materials less the legal deduction of one per cent.

The regulations prescribe that the preliminary entry must show the marks and number of the shipping packages, and the number of tires of each size contained in each package, and the amount used, including waste, of the imported materials. Although the value of the materials in question in a single tire is small, in a large shipment it is worth saving.

"DUTCH" DINNER FOR NEWSPAPER MEN

Newspaper men and the advertising managers of a number of licensed companies were guests at a "Dutch" dinner given to themselves last Thursday at Mouquin's. Many of the representatives of the automobile journals and the New York, Chicago, Boston and Philadelphia daily papers were present.

The celebration started at 10:30 p. m. with a grand march around the floor of the Garden, led by a band. The two-score merrymakers were then transported to the restaurant on one of the new White gasoline trucks, on which they found standing room only. R. H. Johnston was chairman of the committee which arranged the dinner, and he presided over the deliberations of the session, which lasted well into "the cold gray dawn of the morning after."

Testing the Ice on Hudson River with a Maxwell "Q-Sportsman"

The photograph shows Berry Rockwell, advertising manager, and Arthur See, racing driver for the Maxwell-Briscoe Motor Company, visiting Rockland lighthouse, about a mile out from shore at Tarrytown, N. Y. At this point the river is three miles wide. The car weighs 1,400 pounds, and the ice is about seven inches thick

Hoosier Y. M. C. A. a Live One—Manufacturers and retailers of automobiles in Indianapolis are much interested in the automobile course given by the Y. M. C. A. as part of its industrial training. At the opening course, Ellwood Haynes, president of the Haynes Automobile Company, Kokomo, Ind., gave an interesting lecture on the development and various uses of the gasoline motor. Various lectures and instruction periods have been arranged for by the following committee: G. A. Weidley, Premier Motor Manufacturing Company; Howard Marmon, Nordyke & Marmon Company; Will H. Brown, Overland Automobile Company; Fred I. Tone, American Motor Car Company; George M. Schebler, of Wheeler & Schebler; W. G. Wall, National Motor Vehicle Company; Warren D. Oakes, Parry Automobile Company; Frank L. Moore, Fisher Automobile Company, and Fred I. Willis, Hearsey-Willis Company.

Carriage Company's Successful Motor Buggy—The United States Carriage Company of Columbus, O., which recently went into the business of manufacturing motor cars, has designed a combination wagon and call buggy for undertakers which has been quite popular. The wagon is equipped with a gasoline motor and is designed to do the service of both the call buggy and the wagon for the undertaker's assistant. The United States Carriage Company is also equipping a number of ambulances and hearses with motors.

"Get-you-home Tire"—C. S. Averill, of Syracuse, N. Y., together with a number of others is interested in this tire, which is said to be so constructed as to not collapse for several hours after it has been punctured. A test of the new tire was made recently as follows: An automobile weighing 4,800 pounds was equipped with the "Get-you-home" tire; with a large nail and hammer four punctures were made in the tire at noon, after which the car was driven all day around the city without any signs of collapse. The first indications of collapse occurred 18 hours after the punctures were made.

Rambler Truck Rescues Horses—In San Diego, Cal., recently a Rambler automobile hose truck was pressed into service to relieve a team of horses which had become stalled in the mire. The horse-drawn apparatus was on a railroad track with each pair of wheels against the rail down to the hubs in mud. The Rambler truck pulled it out without any damage and with apparently little effort. It is said that this piece of fire apparatus has answered 82 alarms and coverel about 2,000 miles since it was installed there six months ago.

Spokane Dealers to Organize—Plans are being made to organize a Spokane, Wash., auto dealers' association; this for mutual protection. It is expected to have 16 members, taking in every selling establishment in the city, and it is believed that by the organization those concerned will be brought closer together in a business way. It is also proposed to control road races and endurance runs in that vicinity. Harry Ball, L. W. Hodgins, H. P. Banta and J. A. Stoner will back the project.

New Factory for Cleveland—F. E. Stiverson, formerly sales manager for Ohio for the White Company, has organized a company known as the Stiverson Motor Car Company. The company will soon begin the erection of a plant near Cleveland at a cost of $100,000. Stiverson announces that his company will build both four and six-cylinder cars. The car will be known as the Stiverson and will be equipped with several different styles of body.

Hudson Company's Officers—The new personnel of the Hudson Motor Car Company, of Detroit, following its absolute separation from the Chalmers-Detroit Motor Company, is announced as follows: Chairman board of directors, J. L. Hudson; president, R. D. Chapin; vice-president, H. E. Coffin; secretary, F. O. Benzer; treasurer and general manager, R. B. Jackson.

Stein Increases Capital Stock—A recent meeting of the Stein Double Cushion Tire Company, Akron, O., increased its capital stock from $100,000 to $200,000, this preparatory to erecting a large addition to the factory. Increased demand for tires makes this step necessary. The president of the company is C. K. Sunshine and M. M. Neuman is secretary-treasurer.

Inquiries for Factory Sites—The Commercial Club of Superior, Wis., reports that several motor car manufacturers have made inquiries as to sites along the new belt line, the Interstate Transfer railroad, giving facilities for Superior and Duluth, Minn., the twin cities. The steel trust is now erecting the first unit of a huge plant at this point.

Mansfield Rubber Company, Mansfield, O.—At an annual meeting of stockholders the following board of directors was elected: C. H. Walters, F. H. Walters, C. R. Grant, James E. Waite, R. C. Kinnaman, F. M. Bushnell and F. A. Wilcox. A recent fire caused a damage of $16,000 to this plant.

International Harvester Company, Akron, O.—This company is planning to erect several additions to its plant in the Spring. These additions will give it a capacity of 4,000 cars, and for the purpose of carryng out the plans more than $75,000 worth of new machinery has been ordered.

United Motor Company, Denver.—Plans are under way for the erection of a new automobile plant in Denver which it is said will employ between 750 and 1,000 men. The principal product will be an automobile truck designed on an entirely new plan.

Will Make Magnetos.—The Duplex Coil Company, Fond du Lac, Wis., will start the manufacture of magnetos on February 1. New machinery, screw tools and drill presses are now being installed in the factory.

IN AND ABOUT THE AGENCIES

Studebaker Opens Twenty-four Agencies—The Columbus, O., branch of the Studebaker, which was formally opened in a new store room on North Fourth street the latter part of 1909, has placed 24 sub agencies in Central and Southern Ohio, which is the territory covered by the Columbus office. In all 53 counties are included in the Columbus territory. Sub-agencies have been placed in Dayton, Springfield, London, Marysville, Marion, Bucyrus, Ashland, Mansfield, Mt. Vernon, Newark, Coshocton, Bellaire, Athens, Logan, Lancaster, Circleville, Zanesville, Chillicothe, Delaware and Middleport.

New Rainier Agencies—The following Rainier agencies have recently been given out: In Charlotte, N. C., C. C. Coddington will distribute Rainiers for North and South Carolina; H. H. Tifft, Jr., becomes the Rainier agent in Georgia with headquarters at Atlanta; W. H. Johnson will handle the Alabama business with headquarters at Birmingham. The New England distributing point will be Boston, where Rainier cars will be sold by the New England Motor Vehicle Company, 591 Boylston street. Negotiations are in progress for the opening of agencies in the West and Middle West.

Sterling, Cleveland—The Sterling will be sold in Cleveland by the Sterling Motor Sales Company, formed during the week. The company is incorporated for $30,000. J. C. Koepke, general manager of the company, was formerly superintendent of the garage maintained by the Ohio sales branch of the White Company. Several downtown locations are being considered by the Sterling Company and a site will be chosen for a large garage within a few days.

New Pittsburg Selling House.—L. E. Randle, of the Shady Side Motor Car Company, and J. J. Feicht, who is Pittsburg agent for the Reo car, have formed the Liberty Automobile Company. They will have offices and garage at 5958 Center avenue, in the building formerly occupied by the Central Automobile Company, where they have made extensive improvements. Their agencies will be the Regal, Hupmobile and the Hart-Kraft commercial wagon.

Republic Tires, Philadelphia—The Lyman Tire & Rubber Company, occupying temporary quarters at No. 1324 Arch street, Philadelphia, has just closed a deal with the Republic Rubber Company, of Youngstown, O., whereby it has acquired the sales rights for Republic Staggard tread tires in the district included in eastern Pennsylvania, southern New Jersey, Delaware, Maryland, District of Columbia and Virginia.

Rainier, Waverly, Electric, and Crane & Breed Commercial, Philadelphia—The latest newcomer to the automobile trade is the Collings Carriage Company, Inc., with salesrooms at 1719 Chestnut street, which has recently acquired the Philadelphia agencies for the Rainier, the Waverly electric and the Crane & Breed commereial cars, one of the most comprehensive lines in the city.

Everett "30" and Rausch & Lang, Spokane, Wash.—The Pacific Motor Car Company will handle these two cars in addition to the Stevens-Duryea agency which they now have. They will soon break ground for a $10,000 garage. H. B. Housten has been engaged as salesman. Mr. Housten was formerly with the Diamond Rubber Company, San Francisco.

Lovell-McConnell, Newark—This company, which has been located in the Currier building, has outgrown its present quarters and is now erecting a new plant on Emmett street. The new buildings are to include a power plant building and garage. They are well known as the manufacturers of the Klaxon and Klaxonette, both audible signals for automobiles and motor boats.

New Cleveland Agency.—The Crest Motor Company has been formed and will act as Cleveland agents for the Warren-Detroit, the Paige-Detroit and the Abbot-Detroit. Within a short time the company will locate in a large building nearing completion on Euclid avenue, in the heart of automobile row. Demonstrators are expected within a week.

Palmer-Singer and Stoddard-Dayton, Philadelphia—The first of February will witness the removal of the Philadelphia Palmer-Singer and Stoddard-Dayton representatives to new buildings—the former at 336 North Broad street and the latter at 253-255 North Broad street. The "Courier," another Dayton product, has been added to the Stoddard-Dayton line.

Detroit Electric, Cleveland—L. L. and H. R. Applebaum have been appointed Cleveland agents for the Detroit Electric and have located in spacious salesrooms on Euclid avenue. Both are experienced business men and L. L. Applebaum has been connected with the Anderson Carriage Company, Detroit, makers of the Detroit Electric, for several years.

Sternberg Motor Trucks, Chicago—The Western Motor Car Company, of Chicago, has been selected as distributors in Chicago, northern Illinois and northern Indiana for the Sternberg motor trucks, manufactured by the Sternberg Mfg. Company, of Milwaukee. They are now building a $60,000 factory at West Allis, a manufacturing suburb.

American Locomotive Company, Chicago—A new building is to be erected for the Alco branch establishment on the corner of Michigan avenue and Twenty-fifth street. This will be a three-story building with a large sales and storage room for demonstrating and used cars. This branch will be in charge of B. C. Day.

New Milwaukee Quarters for Reo—The Curtis Automobile Company, Wisconsin agents for the Reo, has leased a three-story brick building under construction for its garage and salesrooms. The Reo headquarters have been situated at 180 Fifth street, Milwaukee, for several years.

Billy-Four, Washington, D. C.—Stanley P. Depew has acquired the agency in the District of Columbia for this car, which is a product of the McNabb Iron Works, of Atlanta, Ga. Business will be carried on in connection with the Washington Garage Company, Fourteenth and C streets.

Marmon, Pittsburg—The Keystone Automobile Company, of the East End, will handle the well-known Marmon car in addition to its regular lines, which include the Stoddard-Dayton, Welch, Velie, Columbus, Overland, Courier, and the Rapid motor trucks.

Hopewell, Newton, Mass.—On February 1 Hopewell Bros. will move from Cambridge to Northern Massachusetts, the factory at Cambridge proving inadequate to supply the demand. The new establishment has every facility for filling orders promptly.

Recent Baltimore Agencies—The following cars will be handled in Baltimore as follows: Matheson, E. L. Leinbach; Alco, Neeley & Emsor; Flanders, Dixon C. Walker Auto Company; Hudson, Zell Motor Car Company; Apperson, Boyd, Eastman Company.

Billings & Spencer, Detroit—Owing to an increase of business in the Middle West, this company will establish an office in Detroit with Clair L. Barnes, general sales manager, dividing his time between the factory offices at Hartford and Detroit.

Ohio "40," Pittsburg—The Park Automobile Company, which is composed of H. G. Knapp, J. C. Armor and A. G. C. Quay, and is located at 210-212 West Ohio street, North Side, has secured the agency for the new Ohio "40." The company has a storage capacity of forty cars in a fireproof garage.

Kissel Kar and Maxwell, Janesville, Wis.—The Baack-Reed-Gage Company, of Janesville, recently organized, will handle these two lines for 1910. The new garage is expected to be ready for occupancy on February 1.

Manhattan, Trenton, N. J.—C. B. Ackers has been appointed agent in this city for the Manhattan commercial cars, manufactured by the Mack Bros. Motor Car Co., of Allentown, Pa., which makes one and five-ton trucks and sight-seeing cars.

Parry, New York City—George H. Robertson, one of America's foremost racing drivers, has secured the New York agency for the Parry Automobile Company, of Indianapolis, Ind. He will be located on Broadway.

Mitchell Motor Car Company, Racine, Wis.—The new office building of the Mitchell Motor Car Company at Racine, Wis., is ready for occupancy and several departments are already using the new quarters.

Overland, Hartford, Conn.—E. H. Harris has taken the agency of the Overland which was recently relinquished by A. W. Peard, who introduced it in this section of the State two seasons ago.

Cole "30," Philadelphia—The Stoyle-Vogel Company, Broad and Race streets, Philadelphia, agents for the American, has rounded out its line by acquiring the local rights for the Cole "30."

Kissel Kar, Kenosha, Wis.—The Kent Motor Car Company, of Kenosha, Wis., organized several months ago to handle the Buick, has contracted for the Kissel Kar, made in Hartford, Wis.

Moon Agencies Established — The Moon car will be handled in Buffalo by Geo. G. Buse, in Cleveland by J. H. Greenwald, and in Lexington, Ky., by the Smith-Watkins Company.

Velie, Philadelphia—The Standard Motor Car Company, of 614 North Broad street, has just made a contract with the Velie Motor Car Company, of Moline, Ill., to handle the Velie.

E-M-F and Flanders, Pittsburg—The Pittsburg Automobile Company, Grant boulevard and Seventh avenue, has secured the agency for the E-M-F "30" and the Flanders "20" cars.

National, Detroit.—C. W. Sumner has secured the agency for the National car in Detroit and the State of Michigan. He is the manager of the Racine Boat & Automobile Company.

Franklin, Montreal, Quebec—The Wilson Automobile Company will represent all Franklin products, including pleasure and commercial cars.

Brownlee Auto Company, Austin, Tex.—This company has established a branch agency in Austin; the headquarters is located in San Antonio.

Hudson, Hartford, Conn.—George D. Knox has taken the Hudson for Hartford and Tolland counties, Connecticut.

Reo, Racine, Wis.—Jacob Stoffel has been appointed district agent for the Reo with F. Bosustow as his associate.

PERSONAL TRADE MENTION

Walter G. Pearson, former president of the Pearson Motor Supply Company, New York and Brooklyn, died on January 14 after a prolonged illness. Mr. Pearson was at one time editor and publisher of *Motor Car* and secretary of the Long Island Automobile Club during 1905-1907.

M. B. Fletcher has joined forces with the Premier Motor Car Company, Indi anapolis, Ind. He will act in the capacity of traveling representative for the company. Mr. Fletcher was previously identified with retail automobile trade in Denver, Colo., and has a wide acquaintance in the territory he will cover.

Oscar Stegman is now associated with Landau & Golden, consulting engineers, 1779 Broadway, New York, in the capacity of Western engineer. Mr. Stegman will be located in Milwaukee, Wis.

W. A. Webber, well known to the automobile trade, is now in charge of the Parry Boston Company, Inc., in Boston. He has established temporary headquarters at 2407 Columbus avenue.

Marcus Allen is now the sales manager of the Dorian Demountable Rim Company, 114 Liberty street, New York. He was formerly connected with the Empire Tire Company.

E. O. Wood has become identified with the General Motors Company, Flint, Mich., as assistant to W. C. Durant, chairman of the executive committee.

W. H. Schwartz has been elected sales manager of the Metz Company, manufacturers of automobiles, in Waltham, Mass.

EXCELSIOR SUPPLY STILL EXPANDING

CHICAGO, Jan. 17—An excess of business is gratifying, but sometimes it brings in its wake other things not so pleasant; thus, the necessity for opening a new branch with new ties to make, new friends to find out, and many other similar things. The Excelsior Supply Company, with headquarters at 237 Randolph street, this city, who have for some time carried on a huge supply business on the Pacific Coast, has now found this business so large that a Pacific branch has become a necessity.

So, to look after the interests in this territory, a branch of the Chicago establishment has just been opened with a full line of automobile supplies and Excelsior motor cycles. This will be in charge of T. A. Skinner, well known in the West as one of the Excelsior hustlers, with Frank W. Sanford as his right-hand man.

This centralizing of shipments and the maintenance of an elaborate stock will materially aid delivery both in time and expense. The stock carried will be the most complete line of automobile accessories carried west of Chicago and will run close second to the large supply houses of that city.

Making this a distributing point for the Excelsior Auto-Cycle will materially aid in meeting the demand for this machine on the Pacific coast which has, during the past year, been many times greater than it was possible to meet.

Special attention will be given to all lines of accessories manufactured or controlled by the Excelsior Supply Co.

SNOW REMOVAL BY MOTOR TRUCK

The work of removing the last fall of snow from the streets of New York furnished a striking example of the efficiency and earning capacity of the motor truck as compared with the horse-drawn vehicle. In order to expedite his task, Wm. N. Edwards, Commissioner of Street Cleaning, secured the services of a White 3-ton gasoline truck and put it to work side by side with the horse-drawn wagons so that the comparison between the two might be based on similar conditions of service.

The official figures of the Street Cleaning Department show that the White truck did at least four times the work of the ordinary two-horse truck. First of all, the motor truck carried 10 cubic yards of snow as compared with 5 cubic yards carried by the ordinary contractor's wagon, such as a brick cart. The motor truck was loaded at Union Square, made the trip to the dock at the foot of East Eighteenth street, was unloaded and returned to Union Square in an average of 40 minutes, while the best recorded time for a two-horse truck was 1 hour 20 minutes. The rate paid by the city was 36 cents a cubic yard, so that the White truck earned $7.20 while the best of its horse competitors was earning $1.80.

If the average performance of the two-horse truck was considered, the comparison in favor of the motor truck was even better. At frequent intervals horses would fall down and it was a matter of no small time and labor to get them on their feet again. Again, all of the teams traveled in a beaten track. If one team was delayed all those behind it were halted. The motor truck, under such conditions, would simply pull through the drifts at the side of the road and pass around the stalled teams. Furthermore, the efficiency of a two-horse truck gradually diminished as the day advanced, while that of the motor truck was unchanged. If it had been desired, the White truck would have kept in service for 24 hours a day, by employing another chauffeur, while the hours of service of the horses were necessarily limited by their physical strength.

MORE PLANTS IN INDIANA

INDIANAPOLIS, IND., Jan. 19—A number of new companies for the manufacture of automobiles and parts have been organized during the last few days, while there are said to be several others which will have their organization completed within a short time.

One of the most important recent organizations is that of the Standard Automobile Company at Wabash, which has an authorized capitalization of $500,000. A large number of business men are interested in it, the directors being G. J. Kobusch, W. S. McCall, A. R. Walton, W. B. Phelps and F. D. McMahan.

Another new company is the Diamond Automobile Company at South Bend, which has an authorized capitalization of $50,000. The directors of this concern are J. W. Ricketts, Hannah Ricketts and Grace C. Ricketts.

In this city, the Arthur B. Brown Manufacturing Company has been organized to manufacture tires. The company is composed of W. H. Coburn, F. H. Keller and P. A. Meek and has a capitalization of $10,000.

Another new local concern is the Haywood Tire & Equipment Company, which will do a general automobile and tire repair business. The company has an authorized capitalization of $6,000 and the directors are F. H. Rupert, M. Rupert and M. E. Haywood.

Approximately 35,000 automobiles will be made in Indiana this year, of which 20,000 will be made in this city.

RECENT INCORPORATIONS

Asbury Park Automobile Company, Asbury Park, N. J.—Incorporated with a capital stock of $50,000, by D. C. Haven, F. T. Weeden, W. C. Weeden and L. T. Croce, to manufacture automobiles and conduct a garage.

Wind Shield Manufacturing Company, Newark, N. J.—Incorporated with a capital stock of $100,000, by C. A. Metzger, R. H. Montgomery and R. M. Owen, to manufacture wind shields, automobile specialties, etc.

Maurer Garage Company, of Sheboygan, Wis.—Incorporated with a capitalization of $15,000, by Albert G. Maurer, William Casper and Fred C. Voigt, to conduct a large garage near the Hotel Foeste.

Lotz Auto Company, Detroit—Incorporated with a capital stock of $30,000, by J. A. Lotz, George Christianson, George Cooley and others, to manufacture three types of cars and a new rubber tire.

Alden-Sampson Manufacturing Company, Pittsfield, Mass.—Incorporated with a capital stock of $300,000, by L. E. Sampson and G. E. Mitchell, to engage in a general automobile business.

Hoosier Automobile Company, Garrett, Ind.—Incorporated with a capital stock of $80,000, by J. A. Moore, P. C. Little, J. B. Mager and others.

The Maurer Garage Co., Sheboygan, Wis.—Incorporated with a capital stock of $15,000, by Albert G. Maurer, William Casper and Fred C. Voigt, to conduct a garage.

The Swiss Magneto Company, Madison, Wis.—Incorporated with a capital stock of $20,000, by Bascom E. Clarke, James L. Clarke and E. F. Parkinson.

Connecticut Shock Absorber Company, Inc., Meriden, Conn.—With a capital stock of $110,000. Its purpose is to manufacture automobile devices.

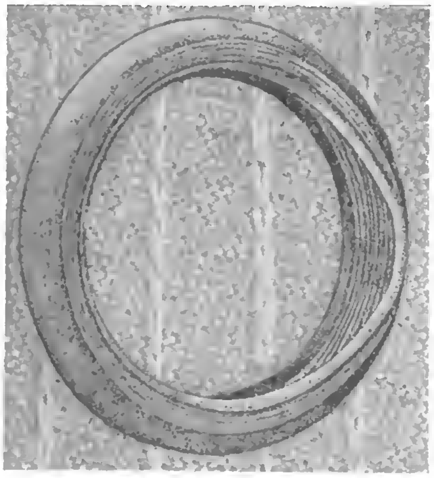
American Engine & Motor Company Dover, Del.—Incorporated with a capital stock of $1,000,000.

Reynolds Motor Car Company, Detroit—Incorporated with a capital stock of $40,000.

White Three-Ton Gasoline Truck Removing Snow in New York City

Information for Auto Users

Bragg Stitched Tires—Exceptional mileage records are claimed for the tires made by the Seamless Rubber Company, of New Haven, Conn., the construction of which is partially explained by the tire name. In the ordinary tire the layers of fabric are united solely by the rubber with which they are impregnated, being otherwise independent of each other. The Bragg Company claims that this is insufficient and that the layers are sure to work apart, thus weakening the tire and finally giving rise to a blow-out. In the Bragg tire the layers of fabric are united by rows of stitching around the circumference of the tread. The carcass of the tire thus becomes practically a solid piece. Twelve thousand stitches is the average number in a tire. The cut shows a Bragg tire in which the rows of stitching appear as lines, against a background of the stitched fabric, full size.

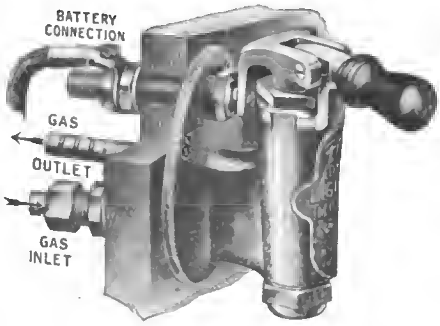


BRAGG TIRE WITH STITCHED FABRIC

The fabric used in the tire is woven of long fiber Sea Island cotton, impregnated between calendar rolls with the finest "up-river" Para rubber. Fabric so treated will not deteriorate as will fabric upon which an inferior grade of rubber is used. The tread is a rubber compound of especially good wearing qualities, to which is due the record of over 10,000 miles without re-treading. The process employed in curing is that known as the one-cure, wrapped tread process. There is no partial curing; the one-cure process assures a uniformity which cannot be obtained by any other method. No metal whatever comes in contact with the rubber of the tread, so that the life cannot be burned out, as may be the case with a mold-cured tire.

"Flash" Lamp Lighter—The greatest objection to acetylene headlights is the necessity of stopping the car and fussing with matches in order to light them. Several attempts have been made, with more or less success, to devise an electrical method of lighting them, and the latest in this line is the "Flash," made by the Motor Specialties Company, of Boston, Mass. The "Flash" is claimed to overcome all the objections cited against former devices of this sort.

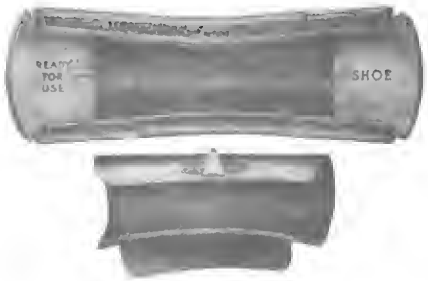
The most important part is the dashboard controller, which combines a gas valve and an electric contact, the timing



FLASH LAMP LIGHTER CONNECTIONS

being arranged so that sparks are brought to the burners before the gas appears at them. A single turn of the controller handle to the left closes the primary circuit through a special single-unit coil, inducing hot sparks at the burners. The same movement opens the gas valve. At the end of this movement the sparks are cut out and the lamps left lighted. A turn in the opposite direction extinguishes the lamps. Current is taken from the regular storage battery or from four dry cells. Regulation of gas pressure is accomplished by the needle valve on the tank, which may be any of the standard types.

Hagstrom Blowout Patch—This handy patch, which has found a good market among automobilists, has been improved for the coming season by the addition of a fabric flap, which passes under the bead of the tire. The patch goes on the inside of the show to be repaired, and is shaped to fit closely. On one side it has a sheet metal hook to fit under the bead. The fabric flap, which is the 1910

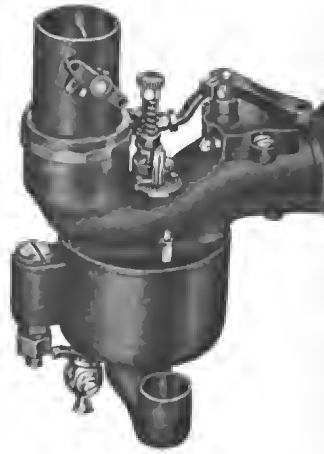


HAGSTROM BLOWOUT PATCH

improvement, is on the opposite side from the hook. The sleeve is applied directly under the blowout of rim-cut, with the hook on the rim-cut side or the side which appears to be the weaker. The flap assists the hook in holding down the worst blowout. It is claimed that old tires past the stage where re-treading would be profitable will still yield several hundred miles service when repaired with this patch.

The Hagstrom Brothers Manufacturing Company, of Lindsborg, Kan., which makes this patch, has also brought out a new soot-proof spark plug. A factory in Stockholm, Sweden, which for generations has been making the finest porcelain in Europe, will provide the insulators for this plug.

The "Siro" Carbureter—The essential feature of this carbureter is a reciprocal mechanism which controls the inflow of air and gasoline under all positions of the throttle. The "Siro" consists of a U-shaped mixing chamber, at one end of which is a throttle valve and at the other a mechanically-operated auxiliary air valve. These valves are so connected that when the throttle valve is being opened the auxiliary air valve also opens in exact proportion. At the bottom of the "U" is a main air inlet concentric with the float chamber, with the gasoline jet in its center. The jet is controlled by a needle valve interconnected with the throttle and the auxiliary air valve. The movement of the needle valve is affected by a cam, adjustable by a pointer on a dial.



THE SIRO CARBURETER

All the functions of the carbureter are thus controlled mechanically, there being no spring-operated valves. At a definite place in the opening of the throttle the needle valve lifts out of the nozzle to supply more fuel for the excess of inflowing air. This action is accomplished by a piece of glass-hard steel sliding up the surface of an inclined plane or cam, which is provided with an adjustment for advancing or retarding its position. The precise setting is determined once for all on any given motor. The adjustment of the carbureter is not subject to atmospheric or climatic conditions. All working parts are in blind bearings, preventing air leaks, and are made of bronze, fitted to gauges and interchangeable. The maker is the Siro Carbureter Company, Springfield, Mass.

"Beats All" Oiled Shirt—This garment has been placed on the market by the Standard Oiled Clothing Company, of 152d street and Tinton avenue, New York, to replace the rubber and gossamer shirts hitherto worn by automobilists. It is not subject to the action of gasoline or lubricating oil, and neither its appearance nor its durability suffer by contact with them. It is thoroughly waterproof and can be easily folded and stowed away, not being liable to cracking.

INDEX TO ADVERTISERS

(Continued on page 60)

IN this issue there are 92 Special Notice advertisers. Six hundred interesting lines of reading matter worth your careful perusal. Somebody wants to sell you a car. Another wants to buy a car. One wants a situation—maybe there is one who wants to employ you. Tires are advertised at a bargain—and you can find several who repair tires. Among the miscellaneous, there is paint and a patent for sale. One advertises for a partner and another wants capital to manufacture and market a new motor.

Correspond with some of the advertisers, or if you are in the field with something to sell, get in line with the others and send us your copy with remittance at rate of twenty cents per line (seven words make a line) and we will put your ad with the "92." For this twenty cents per line we carry your ad to over fifteen thousand subscribers weekly, which by a conservative estimate accepted by publishers generally, means over sixty thousand readers.

Address, THE AUTOMOBILE, 231-241 West Thirty-ninth Street, New York.

(Continued from page 58)

FOR SALE—New unit power plant, 4-cyl., 26-H.P. motor, multiple disc clutch, sliding gear transmission carbureter, coil and timer, muffler, gear-shifting levers, starting crank, $300. Address "Motor" care of The Automobile.

FORD OWNERS and dealers—Send for catalogue showing our outfits to convert any runabout into a handsome roadster; also Rumble and Surrey seats for "N. S. R. T.," enclosed fenders, dash hoods, folding hoods, glass fronts, oilers, magnetos and every part for these cars. Ask for Catalogue A. Write to-day. Auto Rebuilding Co., 1307 Wabash Ave., Chicago, Ill.

FOUR Fisk tires 36-in. x 4½-in. Four inner tubes 36-in. x 4½-in. Not used 125 miles. In fine shape. Rings, clamps and bolts for same. Will be shipped boxed C. O. D. privilege of examination to best offer. Send bids to H. B., 21 Hermon St., Worcester, Mass.

GENTLEMEN'S mink-lined coat, with elegant Persian lamb collar; outside English broadcloth; cost $175; will sell $35; never used; pair beautiful cinnamon bear robes, $30, cost $160; ladies' fur coat, $30. Call or write. J. Roberts, 104 West 114th St., New York.

GUARANTEED TIRES.

36x4½ Anti Diamond	$40.00
34x4½ Anti Diamond	35.00
30x3 Clincher Diamond	12.00
880x120 Hartford Midgeley	50.00
36x4½ Goodrich Bailey	30.00

Coleman's Polar Oils, non-carbonizing, zero test. Write for price list. Ten new Remy high-tension magnetos, with coils, at $35.00; 10,000 Standard and Metric new Wico Spark Plugs at 32 cents. Wm. R. Coleman, 1409 Broadway, New York. Telephone, 3001 Murray Hill.

ONE-CYLINDER Rambler Engine, new, complete, with transmission, radiator, hood, etc., $75 cash. A. R. Co., 1307 Wabash Ave., Chicago.

RADIATORS, hoods, mud guards, metal dishes, gasoline and water tanks. If building or remodeling a car, it will pay you to write us, as we lead in this line. Auto Sheet Metal Works, 2230 Michigan Ave., Chicago, Ill.

RUMBLE SEATS $10 each, Surrey Seats $20 each; Fenders with mat and brass-bound running board, $12 set. Cash with order. A. R. Co., 1309 Wabash Ave., Chicago.

RUMBLE and Surrey Seats made for any car. Name car and send for catalogue. A. R. Co., 1309 Wabash Ave., Chicago.

SECOND-HAND TIRES. Big stock. All sizes. Illinois Tire Co., 3111 Michigan Ave., Chicago, Ill.

STARTER successfully in use on motor car; automatic action, operated by foot lever; applicable to any gas engine for automobile; motor boat or stationary work; compact; demonstration given to interested manufacturers. Licenses issued on reasonable terms. J. W. Tudor, 35 Congress St., Boston, Mass.

TIRE SALE EXTRAORDINARY—All brand new stock. Must sell; mail orders filled, subject to prior sale. Not the kind usually advertised.

P., 25c.; 6-in. Stillson wrenches, 55c.; 8-in. Stillson wrenches, 67c.; thirty-eight only auto clocks, with brass stand, $2.00 each; trunk racks, $2.00 each. Get our No. 65 list. Auto Parts Co., 517 W. Jackson Boul., Chicago, Ill.

$20.00—New 4-cyl. Splitdorf Dash Coil.
22.50—Now 22-25 H. P. Radiator and Hood.
35.00—60 H. P. Radiator and Hood.
7.00—4-Feed Kinsey Force Feed Oiler.
10.00—6-Feed Kinsey Force Feed Oiler.
2.50—15 and 20 Gal. Gasoline Tanks.
3.00—Mufflers.
1.00—Each Quick Detachable Rims.
.50—Each 34x4, 34x4½ and 30x3 Clincher Rims.
15.00—Set Hartford Shock Absorbers.
10.00—Set 4 Wheels with Clincher Rims 30x3½, New, Less Hubs.
These are all highest class accessories. Send for complete list. I. L. Breakstone, 1712 Michigan Ave., Chicago, Ill.

Situations Wanted

CHAUFFEUR-MECHANIC, years' experience and best of references, would like position as demonstrator; would consider first-class driving job; go anywhere. Address "M. P.," care The Automobile.

FIRST-CLASS chauffeur-mechanic, eleven years' experience, desires position as demonstrator with reliable firm, or first-class private position. Address "B. M.," care The Automobile.

TO AUTOMOBILE FIRMS and manufacturers—Wanted position as salesman and demonstrator with automobile firm; best of English experience and references. Driven in all competitions. Apply G. N., care of The Automobile.

WANTED—Opportunity to learn driving and repairing automobiles, with view of buying business or interest in, if satisfactory; well versed in mechanical work. Address E. D., care The Automobile.

YOUNG man, American, thoroughly trained in manufacturing, shop systems and economics, having had several years' experience in the production of automobiles, desires to secure a position as production manager or works accountant. Address "James," care The Automobile.

Help Wanted

AUTOMOBILE oil salesman wanted, familiar with garage trade. Only good men need apply. "L. N. T.," care The Automobile.

INTEND opening branch automobile factory in Indiana; will require heads of departments, assistants, foremen, etc. Address York Motor Car Co., York, Pa.

WANTED—Salesmen and garage keepers to handle second-hand cars in every city of over 3,000 inhabitants. Address Box 87, care The Automobile.

WANTED—By a company manufacturing automobiles, a thoroughly competent and experienced man as head inspector of assembling and testing room. R. F. Ayers, 66 West Broadway, New York City.

Repairing

RADIATORS repaired by experts. Ship to us and follow with letter. A. R. Co., 1307 Wabash Ave., Chicago.

SEND US BROKEN CYLINDERS, crank-cases, etc., to be repaired by autogenous welding. Quicker and much cheaper than ordering replacement parts. No charge unless weld is successful. Estimates and references given. Remember we repair any broken metal parts without solder, pressure or brazing. Try us. Waterbury Welding Company, Waterbury, Conn.

TIRES REPAIRED—Automobile owners, do you want your tires repaired or re-covered by the people who know how? Give us a trial and be convinced. Inner tubes vulcanized at short notice. Jungkind & Vogler, 158 Chambers St., New York City. Telephone 3386 Cortlandt.

Garages For Sale or For Rent

A WELL established automobile business and repair garage for sale; chance for a live mechanic; good terms to proper party; should have some capital; best reasons for selling. Apply L., The Automobile.

CHOICE PLOT, 50x100, in West 47th St., with building, suitable for automobile garage; must positively be sold to partition estate. McDonald, 269 W. 45th St., New York.

FOR SALE—Garage located in the Shenandoah Valley, at Winchester, Va., on the New York-Atlanta Highway; good business location for hotel or printing company. N. A. Cooper, Winchester, Va.

WE HAVE a few choice offices left on the second and third floor of our downtown branch wholesale store, 1327 Race St., most desirable for branch offices of automobile accessory manufacturers. Address Keystone Lubricating Co., 20th and Allegheny Ave., Philadelphia, Pa.

Auto Schools

INDIVIDUAL road work. Small group classes. Day and evening in four or eight weeks' courses. Provision for out of town men. Booklet and pass to visit school on request. West Side Y. M. C. A. Automobile School, 310 West 57th St., New York City. Telephone 3800 Columbus.

THE STEWART Automobile Academy, 231 West 54th St., New York: best equipped motoring school in city; up-to-date motors, chassis and ignition systems; educated, practical instructors; for owners, prospective owners, women; separate courses for chauffeurs; modern cars for road work. Telephone 5409 Columbus.

Insurance

FIRE, THEFT, liability, collision, accident, property damage, and transportation fully covered, lowest rates. Colman Company, 165 Broadway, New York. 'Phone, Cortlandt 2409.

Miscellaneous

AEROPLANE—Mechanical engineer of wide experience desires to communicate with manufacturer interested in aeronautics, that would be willing to undertake the building of an aeroplane possessing great merits; metallic construction; greater speeds and lifting power and automatic equilibrium. Address "M. O. F.," care The Automobile.

FOR SALE—A valuable patent, shock eliminator and eradicator; it is positively simple and absolutely makes riding a pleasure; owner of this patent being a private party has not the time or facility to manufacture same; will sell it outright or on a royalty; prefer hearing from some manufacturer or those connected with automobile trade. Address "Patent," care The Automobile.

PARTNERS WANTED—I have an established, proven business paying $20 to $25 a week now; no competition; excellent chance for ground floor; $1,500 to $2,000 cash insures an equal share in profits which will double income. Apply Box 98, care The Automobile.

THE AUTOMOBILE

DETROIT SHOW OPENED UNDER AUSPICES of DETROIT DEALERS' ASSOCIATION

DETROIT, Jan. 26—Wayne Hotel Gardens on Monday evening, when the Detroit Show opened, presented a scene of activity which has been described as fully representative of the automobile situation in general as it obtains at the heart of the automobile industry. The Detroit Automobile Dealers' Association is the moving spirit in this demonstration in a large way, and it has proven by the results already realized that the 33,000 square feet of available space in the Garden is far from half enough for the purpose.

When the scheme of decoration greeted the eyes of the spectators last year the sentiments voiced were in substance that the last word was said. Sculptor Wagner evidently failed to consider last year's effort in the light of finality, for in all truth the decorative scheme this year is a pronounced, artistic innovation. In a word, the decorative idea comprises a Venetian Garden for the lower floor, and trellis-work through which is entwined Southern smilax, and in harmony with this artistic atmosphere, a myriad of canary birds in golden cages which are placed haphazard, as it were, completes the plan.

View Taken at Opening Time Showing Confusion

Approach to the upper floor is by means of a grand stairway, flanked at its base by two figures of "The Motor Girl" in heroic size, sharing the pleasant task of holding a silken banner between them, indicating the way to the hall above. As the visitor arrives at the head of the grand stairway, "Science," and "Labor" as represented by appropriate statuary extend greeting, and a little further on a graceful arch supports a scroll upon which is blazoned the single word "Progress" brought into bold relief by the proper use of electric lights. The seal of the D. A. D. A. occupies space upon the hangings at the rear of the platform, and the effect from the art point of view is appropriately completed by a trellis-like arrangement of white ropes, scattered through which are mammoth roses and a myriad of electric lights.

Despite the Herculean task, the Garden was in excellent presence on Monday night, agreeable to the scheduled time of opening, and the committee in charge is to be congratulated for having thus disposed of the work in hand. Much of the credit for the excellent work done must necessarily be sub-divided, but Manager John Gillespie, who labored indefatigably from the instant he was chosen for the position, maintained unswerving interest, and displayed an adequate measure of ingenuity resulting in the mastery of each of the intricate problems.

President George E. Lane, Secretary Robert K. Davis, Treasurer J. H. Brady, and Directors George Grand and John P. Schneider, each in his own way worked untiringly in the cause, and as pioneers in the Detroit arena occupy positions of distinction. That the show will prove to be a fitting success, is now well assured, and in view of this splendid effort on the part of Detroit's most capable automobile enthusiasts, it may not be out of place to digress for a pace, and by some prosaic means at hand indicate in a fair measure the material backing which is behind the committee. As representative of the Detroit automobile industry alone, the Detroit show would be one of stupendous proportions. During the coming year it is estimated that Detroit will build half of the country's automobile product.

Some Exhibitors Were Shrewd Enough to Get In Early

Looking through the mist which obscures the real situation, rather than to be dazzled by the extreme splendor of the automobiles which are on parade at the Detroit Show, discloses a situation of the greatest magnitude, and makes comprehension play the part of a dwarf. If some one phase of the great main story is spread out, it may be that it will retain enough of simplicity to enable one to grasp it, and that it will glisten on the polished surfaces of the plate of imagination, and leave the individual in pleasant reverie, is the main expectation. In the building of 100,000 automobiles, which is Detroit's estimate, besides the structures, real estate on which to plant them, and the what-not demanded, there are machine tools—the last of them would span a mile if strung out, after the 90 per cent are disposed of.

REFLECTING THE MACHINE TOOL SITUATION

To build 100,000 automobiles in a single year, requires the dextrous use of the following list of machine tools during a period of 3,000 hours, which is 300 working days of ten hours each.

POWER REQUIRED AND COST PER ANNUM

Considering 60,000 machine tools as being the requirement in the process of making 100,000 automobiles, this means that a power plant will have to be available, capable of delivering 120,000 horsepower, which, per year, is worth, or better yet, will cost $3,600,000, the same to be divisioned off in labor, coal, oil, waste and supplies. This power plant will be at an enormous first cost for buildings, boilers, engines, auxiliaries and dynamos. In the distribution of the power to the machine tools, if an electrical system is utilized, the motors will foot up to $10,800,000, which valuation does not include fittings and installing.

In a general way, not counting pennies, the summary of this cost including machine tools, shafting, belting, electric motors, power plant, and the one hundred and one things which were not mentioned, will foot up to the enormous sum of $84,755,000. Real estate, buildings and kindred costs are not included. This total includes the cost of running the power plant for the year, and, adding depreciation to this, which will be 10 per cent. of the cost of the equipment less the cost of operation, the amount which will have to be charged against the automobiles as "overhead" on account of machine tools, power, depreciation and like factors, will be $11,715,500, or $117 per automobile.

That this view is far from the whole story, is proven by the mere statement that interest on the investment has not been referred to. This item alone, on a 6 per cent. basis, would be $4,866,930, which is $48.66 per automobile produced. Let us not pursue this trend further; as it stands, it is an insight into the vastness of the automobile industry as it obtains in Detroit. In reading about, or glancing over the automobiles at the show, it will add some to the interest, it is believed, to realize that the coming of the automobile has brought prosperity into a host of homes, for, as will be readily appreciated, labor enters into the machine tools, power plant, electrical equipment and the many other things, as well as into the production of the automobiles while they are being made. Let us end by saying that the man who buys an automobile puts bread into the mouths of the children of the men who work in the mines, railroad the materials, and build the machine tools as well as those who make the automobiles, and in this way, according to competent estimates, $500,000,000 in round numbers, change hands per year, and that, too, on the puny basis on which the automobile now rests, puny, it is said, which is in the light of a future of which the show at Detroit is as a cuckoo egg in a robin's nest.

Fixing Up the Exhibit of One of Detroit's Finest

In Detroit the natives claim that it is to be the dominant center in the building of automobiles in the future as it seems to be at the present time. The city offers every inducement to trade, and from the details of the latest acquisition it looks as if Detroit is to have another million dollar automobile plant, as a result of negotiations that were completed to-day. Official confirmation of the announcement in these columns some weeks ago that the Lozier Motor Company would establish a plant in Detroit is made by President Harry Lozier, who is there to attend the local show and also for the purpose of arranging the final details in what will mean the addition of another immense plant to the local motor colony.

Quaker City Show

PHILADELPHIA, Jan. 26—The double-show idea certainly works wonders in providing adequate space for an excessive number of exhibitors, but it also makes trouble for the unfortunate showmen who are forced to clear out one set of cars and install another in the 36-hour interval. Hardly had the first week come to an end at 11 o'clock Saturday night when a hundred khaki-clad laborers entered upon the scene and began their task. First it was necessary to move out the original exhibits; then the spaces must be rearranged and the signs changed, and finally the gathering of pleasure cars, commercials, electrics, and accessories which make up the last half had to be installed.

Fourteen exhibitors of pleasure cars form the nucleus of the second installment. Four electric pleasure cars will be on hand, and eight commercial cars, part gasoline and some electric. Three motorcycle exhibits and twenty-five or so of tires, oil and other accessories will fill up the gaps. This week will witness the official debut here of the Flanders, Halladay, Empire, Otto, Springfield and Cole, Detroit electric, Crane & Breed, Martin, and Packard commercial vehicles, not to mention the reappearance of the Rainier, after two years' absence.

Last week's show was greatly handicapped by the weather, which could not have been worse if it had been especially prepared with a view to keeping everyone indoors. Snow, rain, sleet and slush were supreme for four of the six days. On Wednesday there was a temporary let-up, and then the crowd poured into the Armory in such numbers as to create a new attendance record. Thursday was a "dollar day," which fact, with a few more exhibitions of assorted bad weather, kept the crowd down; but that was the best business day of the week.

It is from a business standpoint that the first week will go down in the records of the Trade Association, whatever the box office figures may be. All of the thirty exhibitors who were doing business last week scored liberally in the matter of sales. Maxwell, Ford, Locomobile, Mitchell, Studebaker and other concerns which use Philadelphia as a distributing center reported a surprisingly large number of cars actually sold, as well as cars placed with the agents. The present week promises to be equally good in this respect.

Of the several local productions which naturally occupy the center of the stage, the only one to make its appearance at the first week was the Bergdoll "30," built by the Bergdoll Motor Car Company. This is a light four-cylinder car fitted, on order, with either touring, baby tonneau or runabout bodies. The motor cylinders are in a block casting, and are 4 inches bore by 4 1-2 inches stroke. Inlet valves, of generous dimensions, are in the centers of the cylinder heads, with exhaust valves in pockets at the left side. The crankshaft, very short and stiff, is carried on two ball bearings.

Motor, clutch and change-gear are all united in a single unit, the crankshaft being formed with a rear extension which surrounds the flywheel and meets a similar extension from the gear case. The clutch is a multiple disc, and the change-gear a three-speed selective, in which a good feature is the milling of the main shaft to form four splines. This motor unit is mounted on a running gear of 112 inches wheelbase, with 34 by 3 1-2-inch tires. Final drive is by a shaft enclosed in a torsion tube, with a single universal joint. A taxicab will be built on the same chassis, the only change of note being the use of 32 by 4-inch tires.

Two more native sons will come in for their share of attention this week, these being the Kline Kar and the Otto. The

Opened Second Section

Kline Kar, which, to be accurate, hails from York, Pa., made its appearance sufficiently early in the season to become quite well known. Two models of pleasure cars are made, a four and a six. Both have cylinders of 4 3-32 inches bore by 5-inch stroke, cast separately. The individual castings, however, are made with large core openings in the front and back of the water-jackets, and are bolted together with these openings registering, to form a continuous chamber for the water. The front of the first and the rear of the last cylinder are, of course, closed by plates. The appearance of the whole is that of a block casting.

For the rest the cars follow standard design. A cone clutch, three-speed selective gear, with annular ball bearings and an enclosed shaft with a single universal joint, complete the transmission of power. The rear axle is semi-floating, also with ball bearings, and the front axle is an I-beam.

The four-cylinder model, rated at 26.8 horsepower by the A. L. A. M. formula, has a 109-inch wheelbase with 34 by 3 1-2-inch tires. The six-cylinder, rated at 40.2 horsepower, is mounted on a 122-inch wheelbase, with 36 by 4-inch tires. For those who desire a speed car, a model known as the "Meteor" has been brought out, in which the six-cylinder motor is mounted on a shorter chassis, with a racing body.

This company also has a light commercial car, which can be fitted with either a stake truck, an express, delivery or wagonette body. The motor is a two-cylinder horizontal opposed, water-cooled by thermo-siphon circulation, and drives through a two-speed planetary gear and side chains. The standard wheelbase is 86 inches, and the tires are 36 by 3-inch solid.

The Otto Gas Engine Works, a firm known all over the country for the excellence of its stationary engines, has entered the automobile field with a four-cylinder car of medium size, which seems likely to still further increase its reputation. The motor follows the very latest practice in having a slightly longer bore in proportion to its stroke than is customary, the figures being 4 3-8 by 5 1-4 inches. Cylinders are cast in pairs, with all valves on the left side. A true honeycomb radiator, with fan, and a centrifugal pump mounted on the right side of the motor, take care of the cooling. The Bosch dual ignition system is used, the magneto being driven from the rear end of the pump shaft. The motor and its accessories are mounted on a sub-frame hung from the front and middle cross-pieces of the main frame.

The change-gear, a three-speed selective, is made a unit with the rear axle. The torsion tube which encloses the drive shaft is supported from the frame cross-member at its forward end by an original linkage, which has the effect of a ball or universal joint, allowing it to swing in any direction, while at the same time it is positively held, and all strains are taken off the drive shaft. In addition the rear axle is provided with two radius rods.

The Otto is made in three styles, a full tonneau, baby tonneau and runabout, with tires 34 by 4, 32 by 3 1-2 and 34 by 3 1-2, respectively. The weights average about 2,000 pounds. The wheelbase on all is 123 inches. The cars are all hung low, and this, combined with their long wheelbase, gives them a rakish appearance whicb many autoists find attractive.

Although Philadelphia has never claimed to be in the front rank as an automobile building city, especially now that outputs are rated in the thousands and tens of thousands, nevertheless, the old Quaker City has no reason to be ashamed of its product. With the addition of these newcomers it will attain still further prominence in the automobile world.

D—Novel rear axle construction of the Waverley electric, in which the drive is by a shaft parallel to the axle itself

LICENSED ASSOCIATION FAST ASSUMING DUE PROPORTIONS

FOREIGNERS TAKING OUT LICENSES UNDER SELDEN PATENT

MANY MAKERS STRUGGLING WITH A COMPLICATED SITUATION

THE latest understanding in relation to licensed relations of the various companies is reflected in the licensing of the Lancia Import Company, under a special form of contract, to import and sell automobiles in the United States.

From present appearances, considering the most authentic information available, it seems that the A. L. A. M. proposes to be liberal in its dealings with companies which can show that they are responsible, and especially if they have vested rights. The newcomers, however, seem to be anxious to know just where they are at, and, from all that can be learned, this is the question of the hour.

To sum up, taking the situation as it can reasonably stand discussion of, the makers of automobiles in America who were actually engaged in the manufacture of cars when the court decision was rendered, have nothing to fear for the future, excepting that they have to make terms; that the terms will be liberal and just is assured. Importers, if they were actually engaged in the trade before the date of the decision, will be able to make terms just as the Lancia concern has succeeded in doing.

Those who are shivering on the outside, and are likely to have a little trouble in getting near the stove, are, according to the evidences, makers of automobiles who went into the business after the famous court decision was handed down, disregarding all the attending facts. This will be especially true, unless they can show that they are in for the good of the automobile business as a whole.

GLIDDEN TROPHY MAY NOT BE ABANDONED

NEW YORK, Jan. 27—These are busy times for Chairman S. M. Butler of the A. A. A., due to the shower of protests which are reaching the Contest Board, following some preliminary discussion having for its purport the elimination of the Glidden Trophy from the acreage of contest. The meeting of the Board on the 25th instant, which numbers in its membership David Beecroft of Chicago, F. B. Stevens of Rome, N. Y., T. A. Wright of Wilkes-Barre, Pa., and Joseph H. Woods of Newark, collaborating with Chairman Butler.

The meeting of the Board seems to have been rather protracted, and the principal matter of discussion was, first, as to the expediency of any further effort involved in the Glidden Trophy. The consensus of opinion being that it would be ill advised to abandon the trophy at this time in view of the wide interest which is taken in it by the makers, the public at large and automobile drivers and owners in general.

Conceding that the trophy will be contested for, the next matter of great importance and knotty characteristics lies in the selection of the route. While this is a matter which cannot well be settled off hand, and which may demand the sending out of a "path finder," it is nevertheless likely to fall to a Southwestern orbid. The meeting adjourned without having taken definite action on either of the questions, but the sentiment seems to be in favor of a run of a reliability tone which will start from Cincinnati and take in Memphis, Tenn., Dallas, Tex., and Oklahoma, ending at Chicago. The fear has been expressed that many of the roads which might be included in this circuit are quite impossible to any sort of vehicles, and a pathfinder may have a stout task in front of it in the process of surveying the boundaries of the route.

NEW CONCERN FORMED OUT OF BROWN-LIPE

The Brown-Lipe-Chapin Company, with a capitalization of $1,500,000, has been organized in Syracuse, N. Y., to take over the differential gear department of the Brown-Lipe Gear Company. C. S. Mott, of the Weston-Mott Company, Flint, Mich., is the only stockholder not in the parent corporation. During the past two years the present plant of the Brown-Lipe Gear Company has been worked day and night with 825 employees. The increasing demand made it necessary to separate the differential gear department from the transmission and steering gear department to provide sufficient room for the latter.

The business of the new company will be managed by H. W. Chapin, who for the past fifteen years has been general manager of the Brown-Lipe Gear Company. He will retain this position in addition to his new one. The new company will assume all of the differential gear contracts of the parent, and all the machinery and equipment used by the latter in this branch will be turned over.

REDUCED R. R. RATES TO CHICAGO

The Central Passenger Association will grant the rate of one-and-a-half fare to visitors to the Chicago show on account of the A. A. A. Convention. Ticket agents will issue certificates for this purpose, which will be validated at the headquarters of the A. A. A. in Chicago. They will be good only provided one thousand or more are presented. Membership in the association is not essential.

CLEVELAND ALSO BOOKS TWO SHOWS

CLEVELAND, Jan. 25—With the exception of a small amount of gallery space, the entire floor of Central Armory has been allotted to prospective exhibitors at the show to be held during the week of February 19 by the Cleveland Automobile Show Company. A great demand has also been manifested for space in the second show, to be held during the week of March 5. This exhibition will be conducted by the Cleveland Automobile Club, also in Central Armory.

SUBSCRIPTIONS — NATIONAL CONVENTION

The latest revised list of the paid-in subscriptions to the National Convention fund of the A. A. A. as reported by Charles Thaddeus Terry, chairman, shows a keen interest on the part of the clubs, as the following list indicates:

Name of subscriber.	Amount of subscription.
Automobile Club of Buffalo	$500.00
Quaker City Motor Club	100.00
Pennsylvania Motor Federation	250.00
Springfield Automobile Club	200.00
Automobile Club of Southern California	125.00
Albany Automobile Club	50.00
Oliver Crosby (individual subscription)	25.00
Automobile Club of Pittsburg	50.00
Automobile Club of Hudson County (N. J.)	100.00
Automobile Club of Auburn	150.00
New Jersey Automobile and Motor Club	200.00
Atlanta Automobile Association	200.00
Associated Automobile Clubs of New Jersey	100.00
Denver Motor Club	50.00
Long Island Motor Club	300.00
Automobile Club of Philadelphia	250.00
Delaware Automobile Association	50.00

AUTHENTIC FIGURES OF AUTOMOBILE PRODUCTION

INTEREST seems to center in forecasts of the automobile production for the season of 1909-1910, partly because of the general interest which is taken in the industry, and for the rest—in view of the known facts—automobiles are undoubtedly being turned out at an enormous rate. The chart here given was made under the direction of Alfred Reeves, General Manager of the A. L. A. M., and it is the net result of a very careful canvass of the whole situation within the confines of the licensed association. Just what number of cars should be added, considering unlicensed builders, is a matter which will have to be left to conjecture.

At all events, a brief statement of facts, based on this chart, is extremely interesting, the figures being as follows:

PERCENTAGE PRODUCTION OF AUTOMOBILES SINCE 1905

Years.	Percentage.
1904 over 1903	80
1905 over 1904	51
1906 over 1905	41
1907 over 1906	18
1908 over 1907	17
1909 over 1908	139

Authentic figures on the production of motor cars during 1909 have been compiled by the Association of Licensed Automobile Manufacturers, and show a startling increase over the production of 1908. The figures indicate that the licensees under the Selden patent alone made 94,891 cars. This is believed to be about 85 per cent. of the cars made. The compilers have added to these figures 20,000 cars as the product of the outsiders, making a total production for 1909 of 114,891 cars—far in excess of what was indicated six months ago, when it was declared that 80,000 cars would be made.

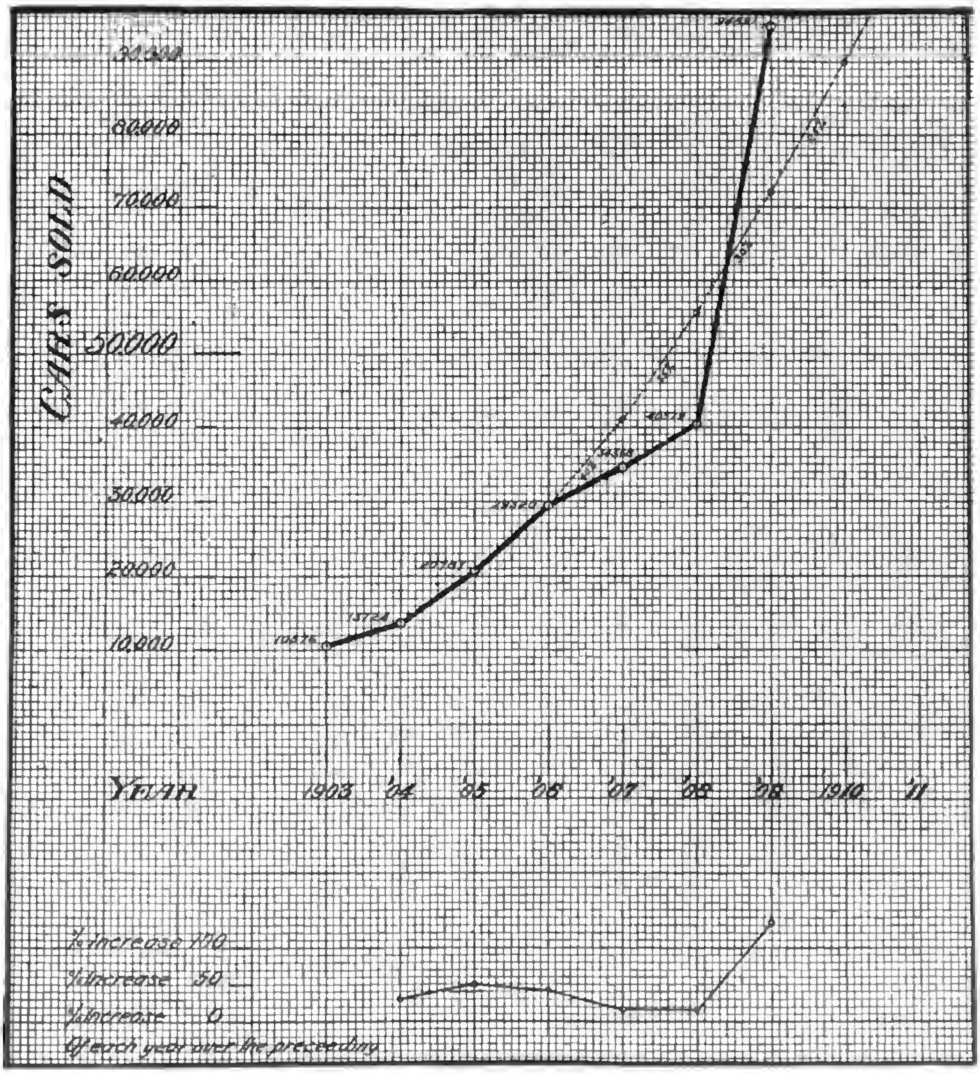
The figures indicate very clearly that production has reached a point that warrants at least a careful look into the future by the makers. There is nothing on the business horizon now to indicate that the present year will be anything but a prosperous one for the motor-car builders; yet the figures shown on the accompanying chart, prepared and issued by the A. L. A. M., are worthy of the deepest thought.

Prior to the decision sustaining the Selden patent last September, the business of the motor-car builders was divided about half in the Selden camp and half among the outsiders; but since the decision and the application and granting of licenses to a score or more additional makers the licensed product amounts to not less than 85 per cent. of the total business, and includes the cars of almost every concern of standing. All the Selden patent licensees conduct their business independently of the others and in strict competition.

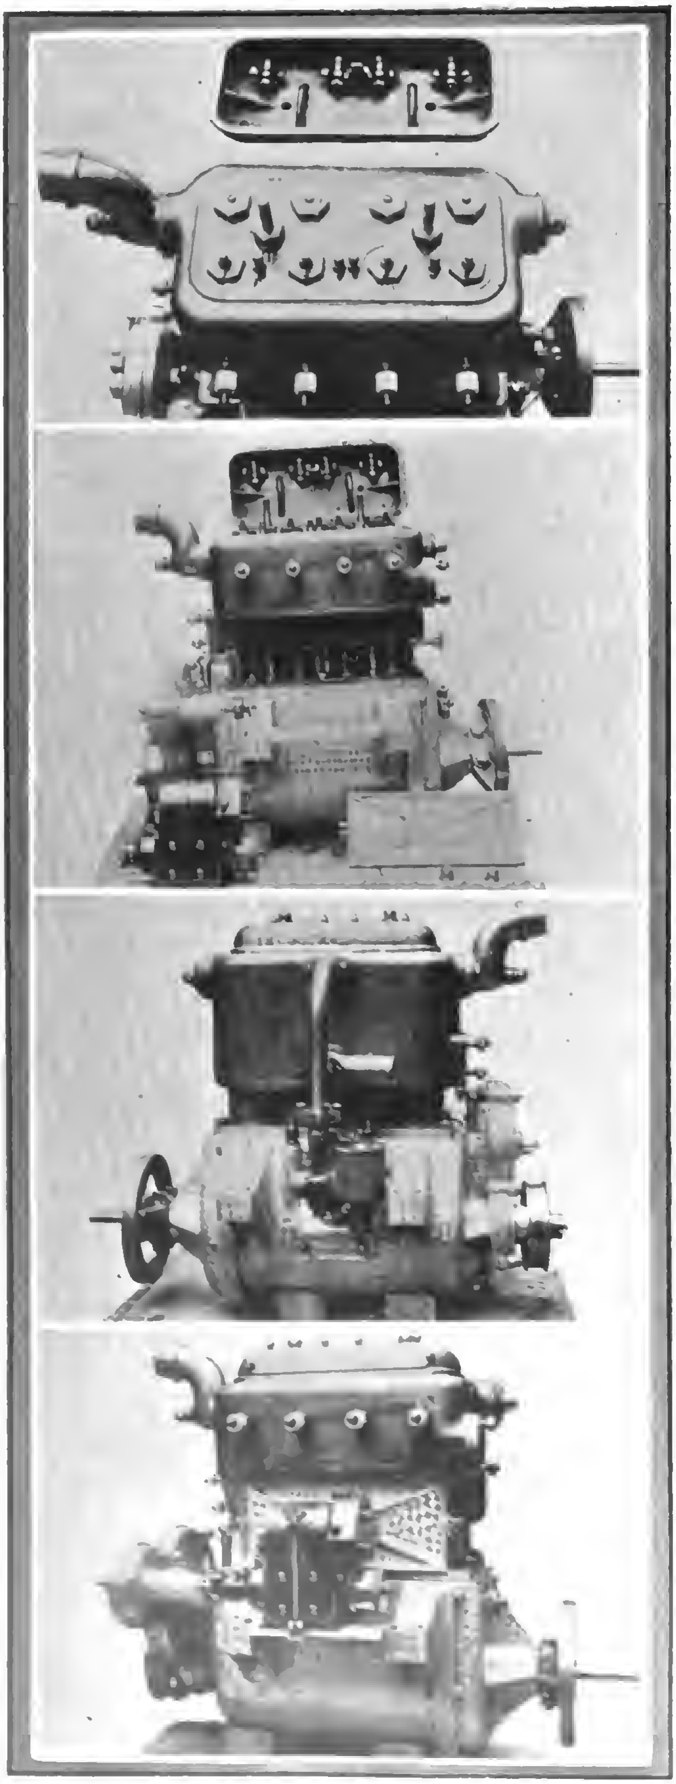
All attempts thus far to arrive at anything like accurate statistics which would reflect the magnitude of the automobile industry were rendered futile by the competition which was in evidence when partisans, in the interest of their cars, made bold to proclaim the number which they would build. Watering stock has been reduced to a science, but watering the figures of some of the estimators became so troublesome as to be rendered impotent. To illustrate how uncertain some of these guesses really are, it is pointed out that in an estimate which was made last year one well-known company said it would build 1,500 automobiles and another well-known company said it would turn out 5,000 cars. The company which said it would build 1,500 automobiles made good, and had a little margin to spare, but the company which said it would build 5,000 cars reached the magnificent figure of 80 cars by dint of hard labor.

This uncertainty is present in all estimates of the number of automobiles which will be turned out, to a sufficient extent when the situation is carefully canvassed by a competent statistician, provided he is in touch with the source of information and is perfectly familiar with the character of the work in hand. One way which has been tried with some success is to check all the statements of the makers of cars against all the statements of the makers of accessories and thereby strike a balance.

This method of arriving at an approximation of the extent of the industry has been tried out at some length, and it served very well to bolster up the contention that this year is a large one in the automobile business, and that most conservative estimates are just a little conservative. The chart here produced reflects the whole situation with much accuracy.



Number of Cars Made by Selden Patent Licensees During 1903-1909, as Estimated by A. L. A. M.



Showing How the Overhead Inlet Valves Are Operated
Details of the Monobloc Engine Valve Mechanism
Illustrates the Compactness of This Form of Engine
Magneto and Valve Side of the New Engine

A GOOD EXAMPLE OF MODERN TENDENCY

PARIS, Jan. 18—A good example of modern tendency in motor construction is to be found in a monobloc production by Chapuis & Dornier, a French firm building motors exclusively for the trade. The greatest demand in Europe at the present moment is for low-powered four-cylinder motors, as small, as light, and as silent as possible. The overall length of motors has been cut down in a remarkable degree since the introduction of the monobloc method of casting, and the limit appeared to be in the valves. With a single camshaft and eight valves in a pocket all on one side it was not the size of the engine bearings which proved an obstacle, but the valves, if these were to be of sufficient size to allow of adequate feeding of the motor. It was possible to superimpose them, by working the inlets from rocker arms, and maintaining a single camshaft, but this is not a solution that appealed to the constructor, for the user desires a motor that has no visible working parts, that looks, indeed, like a metal box with a few pipes and four plugs attached.

The Chapuis & Dornier solution is to employ a single camshaft, with exhausts operated from below and intakes immediately above operated by a special type of overhead mechanism. This design allows the cylinders to be placed as close together as possible compatible with a safe amount of metal in the walls. The thickness of the wall between the cylinders is 5 millimeters, and as a central bearing is not employed the overall cylinder length of a motor of 2 9-10 inches bore is only 15 inches. The four cylinders being responsible for almost 12 inches of this, the remaining 3 inches give the necessary amount for metal in the walls and for water jacketing at each end. The total overall length—from tip to tip of the crankshaft—is practically twenty-eight inches.

With good castings the makers declare that an engine of these dimensions will furnish adequate power without any danger of warping. The short length of the crankshaft makes a central bearing unnecessary, thus doing away with the difficulty of lining up a three-bearing crankshaft, and at the same time leaving an ample bearing for the connecting rod ends. By superimposing the valves it is possible to obtain a very large area, the diameter of the valves on this motor being a little more than half the bore of the cylinders. On of the disadvantages of the many monobloc motors has been the small area of the valves, resulting in a perpetual starving of the cylinders. There is nothing of particular note about the exhaust valve mechanism. The intake is operated from above, but instead of the vertical push rods being external, they pass through the pocket, in which they are guided at two points, and project above the cylinder head. The rocker arms are mounted on the inner face of an aluminum housing secured to the cylinder head by nuts fitting on two projecting bolts. One end of the rocker receives the pushrod, while the other fits on the extremity of the projecting inlet valve stem. The vertical push rod is provided with means for taking up any play which may be produced.

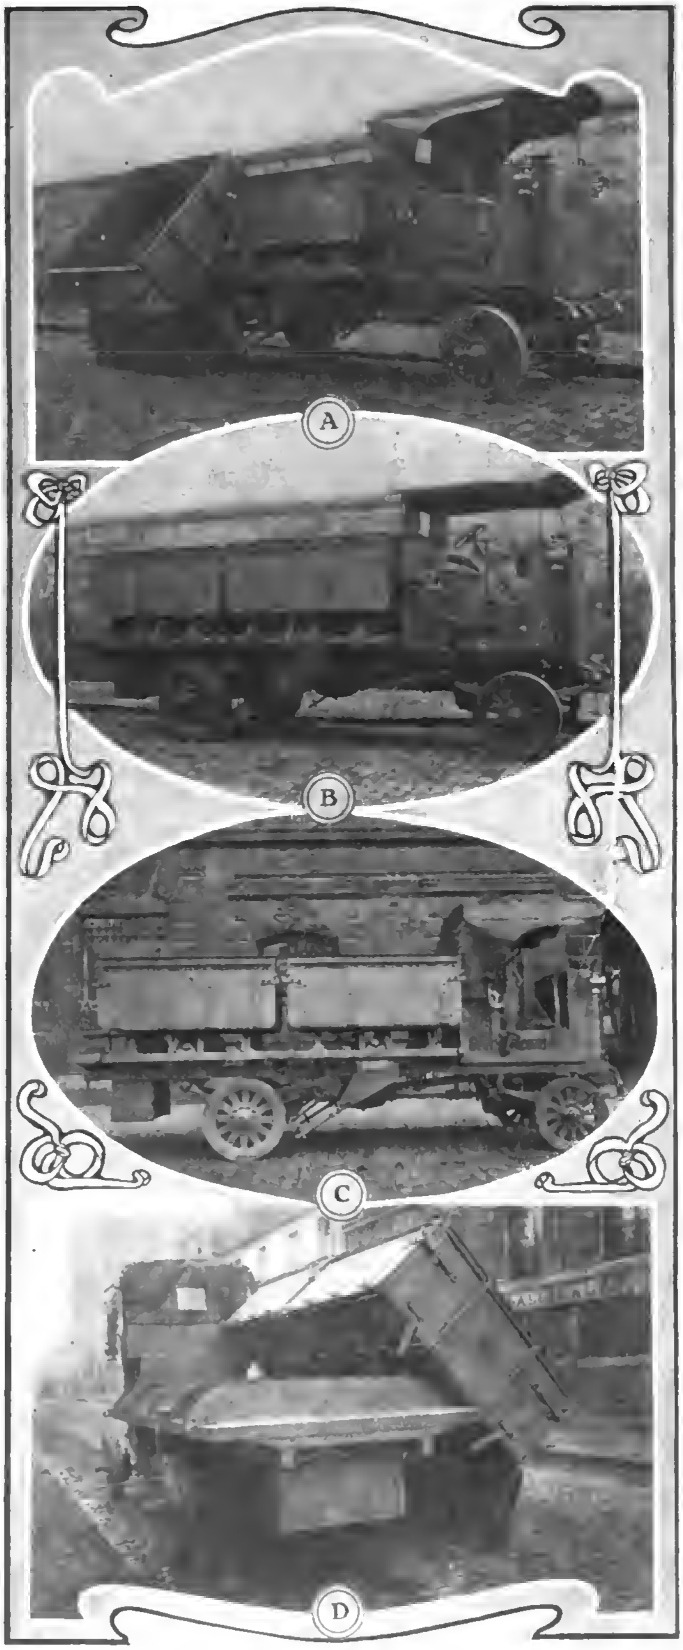
In addition to carrying the rocker arms, the cover completely encloses the cylinder head and hides from view all moving parts. As the valve stems are enclosed by an aluminum plate secured by a couple of thumb screws, there is no moving part visible excepting the extremities of the mainshaft. The plugs are carried in the side of the engine, between the inlet and exhaust valves, and on the same side as the magneto, thus necessitating very short leads. Water cooling is by thermo-siphon circulation, the space around the cylinders being adequate and inlet and outlet pipes of very large diameter.

The feature of the crankcase is that it is entirely of one piece with the exception of the end plate stoutly bolted in position. It is claimed for this design that there is an increase of strength compared with the usual type of base split longitudinally. Naturally it prevents leakage of oil, for it is easy to make the single joint oil tight, but it is not possible to inspect the connecting rod ends without taking down the motor. Timing gears are enclosed in an aluminum housing at the forward end, and merely consist of three pinions, the main one, on the crankshaft, having an elastic mounting to prevent "chattering" of the pinions on quick changes in the speed of the motor. The gudgeon pin also is mounted with a couple of special spring washers giving the necessary slight lateral play but without any objectionable metal-to-metal rattle. The carbureter. is carried on the right-hand side of the motor, with a single lead to the intake manifold cast with the cylinders and warmed by the circulating water. Normally lubrication is by splash, and with this object in view as much metal as possible has been left on the upper face of the crankcase, and the opening is further closed by a baffle plate allowing the connecting rod to pass with an easy fit, but preventing the passing of an excessive quantity of oil. The end of the crankshaft is provided for the fitting of a lubricating pump if desired. Three models are built of respectively 2 9-10 by 4 7-10 bore and stroke; 2 7-10 by 4 7-10, and 2 1-2 by 4 3-10. It will be noticed that in all cases the ratio of stroke to bore is high.

After nearly two years' exhaustive tests, the Panhard-Levassor Company has decided that the sliding valve motor invented by Charles Y. Knight, of Chicago, has made good its claims and can be produced with the guarantee of the Avenue d'Ivry factory. During the past six months several of these motors have been on the road fitted to cars owned by private members of the firm. The first series will be produced, in all probability, about June next, and will be of a very limited nature. Unless the motor acts quite differently in the hands of private owners from what it has done when driven by the experts, a large series will be built for the 1911 season. The cars at present on the road are declared to have a rating of 15 horsepower, but as they are capable of averaging 45 miles an hour on French roads, with a closed body and four passengers, this rating can certainly be taken as extremely conservative. It is very improbable that the Panhard-Levassor Company will build all their models with the Knight engine, as has been done by the Daimler Company in England, but will fit it to the larger models of respectively 15 and 25 horsepower, both with shaft drive. The only other Continental firm at present building the Knight motor is Minerva, in Belgium. Mercedes has secured the rights in Germany, but does not yet appear to have made a move.

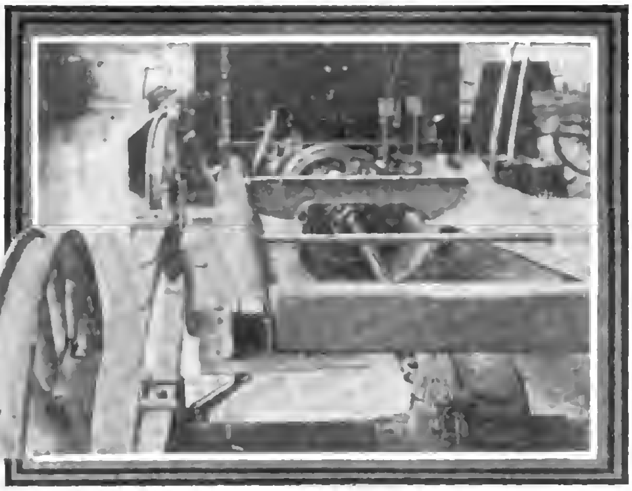
Power vehicles have played an important part in the construction of the Paris underground electric railway, but up to the present have always been of the steam variety. The latest type, to be adopted for this work is a tip wagon driven by a Cohendet, a two-cylinder vertical motor of 5 3-5 inches bore and stroke. The power plant seems small in comparison with the work that has to be done, but as the vehicles constantly deliver 5-ton loads from the boring in the city to the suburbs or the river wharf, it would appear to be sufficient. The motor is carried forward, under the driver's feet, and low down to secure a perfectly horizontal drive to the gear box and countershaft. Four speeds and reverse are provided, and final drive is by side chains.

As a truck of this nature can never expect to receive tender treatment, there is a big margin of safety in all the organs. Solid rubber tires have had to be discarded for reasons of economy, in favor of metal bands, with springs, however, made specially long, and shock absorbers fitted in order to protect the mechanical organs as much as possible. Even the radiator has been abolished as too fragile an organ for this class of work, and its place taken by a very large water tank with condenser. The tip wagons are all metal, mounted on rails, and capable of being tipped either left or right by hand-operated gearing. These vehicles show the great care with which the French constructors design and build specially for every class of work.



Cohendet Double Tip Wagon Operated in Paris
The Two Hoppers Easily Accommodate Five Tons of Earth
Showing Substantial Construction of Steel-Shod Wheels
Hoppers May Be Tipped Either Together or Singly

As so much of the labor in their factories is hand work, which is relatively cheap here, they can do this to much better advantage than the American constructors. In cases like the present instance, the system of individual construction produces vehicles of remarkable efficiency in service.

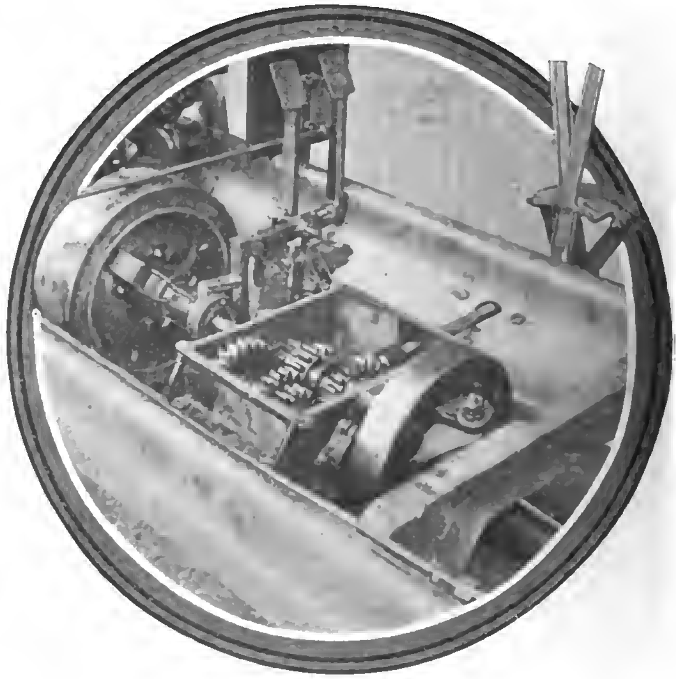


Appearance of the New Darracq from the Rear.

EXTREME SIMPLICITY FEATURE *of* DARRACQ

PARIS, Jan. 19—At a time when good automobiles are far from being the exclusive production of any one firm, more than ordinary interest attaches to a car which even causes constructors to sit up and take note. The new Darracq can claim to have created more than a mild sensation on the European market, for it is a four-cylinder car of 14 nominal and 19 actual horsepower, sold complete with touring body at only a fraction over a thousand dollars. The secret of the low price lies in a simplified and labor saving design, rather than in an unusually large series, though, of course, it is believed that the new production will figure well on the sales lists. Its first success has been on the English market, where the requirements are a medium-powered touring car as simple, silent, speedy and cheap as it is possible to make it.

Extreme simplicity is indeed the outstanding feature of the Darracq chassis. It is so clean cut, indeed, in comparison with the average chassis, that the first impression is that the vehicle is not complete. But if organs have been suppressed it is only because they are useless, and their abolition would entail a decrease in weight, the use of less material, a saving of labor in fitting, and a cheapening of the cost of maintenance. For instance, the frame members have been redesigned to lessen labor in assembling. The section is an inverted U, stamped out complete with dumb irons and an inswept portion forming an integral subframe for the motor and gear box, or, in other words, allowing the motor and gear box to be mounted direct to the frame without the use of side arms. All the labor necessary on the chassis proper is the placing in position and riveting of three cross members, also of inverted U section, one at each end and one in the center. Add to this a sheet-metal underpan, rivetted to the extremities of the inswept frame members, and the constructor has, in addition to a rigid frame, a structure on which all the mechanical organs are fully protected from dust and mud. The pan is pierced in one place only, for the passage of the oil plug in the base of the crank chamber. The inswept portions of the side members are pierced in three places only, for the passage of the drag link on the steering gear, the change speed and brake connections and the exhaust pipe. In passing it is worth mentioning that the exhaust pipe is the shortest ever fitted to a touring car. From the exhaust manifold cast with the cylinders, a short straight length of pipe passes directly into the exhaust box immediately below on the underside of the frame. It is only a detail, but it is sufficient to show how everything has been worked out with a view to simplicity. An additional advantage of this type of frame, which is a production of the well-known Arbel establishment, is that the body work is brought fully four inches lower than would otherwise be possible. It does not rest on the highest portion of the frame member, but on the two flanges.



Central Part of Chassis, Showing Transmission and Control.

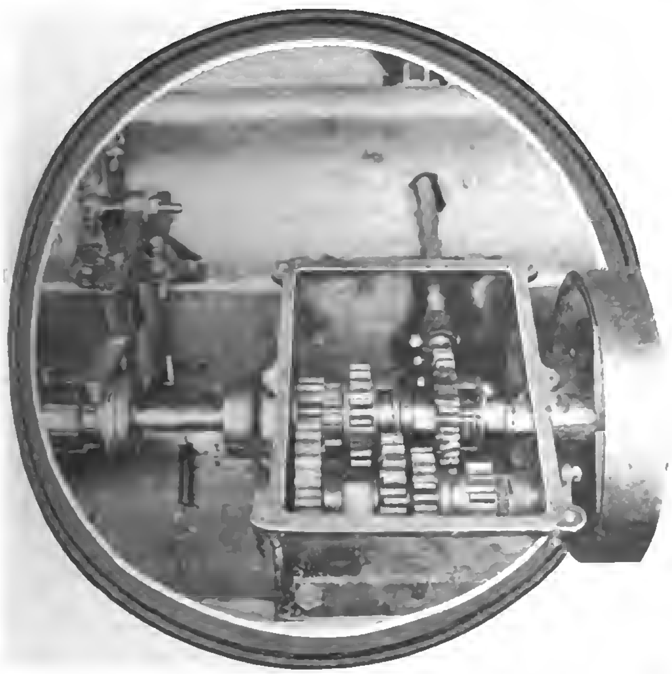
Valve Side of Engine, Showing Exhaust and Carbureter.

The motor is a four-cylinder in one casting, valves all on one side, intake and exhaust manifolds cast integral with the cylinders, and the latter ribbed for cooling. Cylinder dimensions are 3.3 bore by 3.9 stroke. Piping is reduced to a minimum. The exhaust, as already explained, is a twelve-inch length without a bend in it. The intake is just as simple, consisting of a short vertical tube, the upper end of which screws into the intake manifold and the lower end fits round the vertical jet. Throttling is done at the upper end of the tube, and at the same point is an automatic additional air inlet. The feature is one that first made its appearance on the 1908 Charron, but has since been adopted with detail modifications by a number of leading makers.

The water pump is retained, contrary to the more general tendency on medium powered European cars, the constructors being of the opinion that the slightly increased complication is more than paid for by the decrease in the size of the radiator and the weight of water carried. The pump is of the centrifugal type worked off the same pinion as the high-tension Bosch magneto. The timing gears thus resolve themselves into three pinions only, all enclosed at the forward end of the motor. A ventilator fan is carried, driven by flat belt off the main shaft.

The feature of the motor is undoubtedly the lubrication, which is of the forced feed type, but without any visible pipes, and without any dashboard fitting suggestive of oiling. The lower portion of the crankcase forms an oil reservoir, the filler—and at the same time breather—which is on the right-hand side of the motor, the driver's only care is to keep a sufficient quantity of oil in this tank. This is made easy by placing in the oil reservoir a balanced wood float, to which is attached a vertical rod projecting through the cap of the breather and filler. The length of spindle showing above the filler cap is indicative of the amount of oil in the case.

The oil pump is contained within the crankcase, and is operated by an eccentric on the camshaft, the lubricant being forced to all the main bearings, while the connecting rod ends are lubricated by splash from a shallow trough in which a constant level is maintained, the overflow returning to the oil well in the base of the chamber. The working of the pump can be verified by a tap



Closer View of Transmission, Showing Gear Sizes.

on the upper portion of the crankcase, and the piston of the pump can be withdrawn through the plug in the chamber.

The clutch is of the cone type, with springs behind the leather, and is in no way distinctive except by reason of the ease of dismounting. The gear box gives three speeds and reverse through a gate change. Owing to the form of the chassis only very short arms are necessary to attach the gear box to the frame members. An interesting detail is that the gear shifter is mounted on the shaft operating the foot brake at the rear of the gear box. The feature of the rear axle is the entire absence of a torque stay, this work being performed by the three-quarter elliptic springs, the seatings of which are made stronger in view of this work. Control is entirely on the throttle, through a foot accelerator, the sparking point being fixed. The dashboard is perfectly clear. There being no lubricator or pressure indicators to verify, the car is a remarkably easy one to handle. The first series of vehicles now being produced consists of open touring cars with five-passenger body. It is declared that the same model will be used for taxicab service, and that an order for 3,000 of these vehicles is now in hand to be sent to India.

Complete Chassis, As Viewed from the Front.

SHIPMENT BY TRUCK—LONDON TO PARIS

Paris, Jan. 20—The first attempt to compete with railroads in the matter of international transportation of goods has been made by the firm of Waring & Gillow, furniture dealers having establishments in London and Paris. The ordinary method is to ship goods by rail and steamer, closed vans, capable of being slung from truck to train and from train to steamer, always being employed when a full load is available. As there was a considerable amount of traffic between the London and the Paris houses, and it frequently fell to the firm to make large removals, the experiment was tried of shipping by auto.

After loading at the London house the driver of the three-ton truck covered the 80 miles separating the British capital from New Haven, and there ran the vehicle on board the cross-Channel steamer under its own power. On landing at Dieppe there were custom formalities, naturally, but with the aid of the triptyque system and the facilities which can be established when a regular service has been organized, this should not occasion any delay.

In the matter of time the automobile service is a distinct advance on the railway, for it is possible to leave London with a full load in the morning and deliver in Paris on the evening of the following day. By the ordinary method three days would certainly be necessary. At present it costs a little more to transfer goods by automobile instead of by rail. With a well-developed service, however, the cost can be brought down so low as to compete very favorably with the railway, while if account is taken of the lessened risk of breakage, there is a decided advantage in favor of the automobile. Although the present service is only between London and Paris, it is planned to extend it later to include all good roads radiating from London.

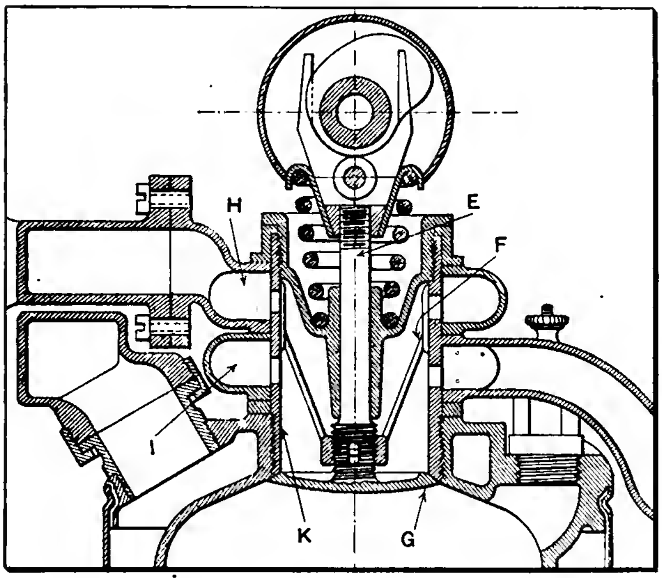
NOTES OF UP-TO-DATE PRACTICE IN EUROPE

FOREIGN practice, in a way the progenitor of the American. offers many suggestions to the wide-awake engineer. However, as the perusal of the representative English, French and German magazines consumes more time than a busy man would devote to this subject, THE AUTOMOBILE will endeavor to summarize in each issue a number of examples taken from foreign exchanges. Care will be taken to give the name and date of the magazine quoted, in order that it may be possible to refer to the original source for additional information.

Combined Inlet and Exhaust Valve—Palous & Beuse have brought out an extremely simple four-cylinder aeronautic motor, which is described in *Der Motorwagen,* December 10. The most distinguishing feature is the use of a single valve for the inlet and exhaust in each cylinder, driven by an overhead camshaft.



Palous & Beuse Combined Inlet and Exhaust Valve

In the head of each cylinder is a single valve port, normally closed by the valve G. The valve cage K, screwed into the cylinder head, has two circumferential rows of holes, the lower for the exhaust and the upper for the inlet. These holes are opened or closed by a sleeve F attached to the valve stem. The camshaft has for each cylinder a single cam of an unusual profile. The upper end of the valve stem has threaded directly on it a yoke encircling the shaft, to prevent rotation of the stem, and also carrying the roller upon which the cam bears. For the exhaust the cam presses the valve down about 6 mm., opening the valve proper and bringing the lower edge of the sleeve F down to the row of holes for the exhaust. At the end of the exhaust stroke a further downward movement causes the sleeve to cover the exhaust holes and open those of the inlet. Finally, the valve returns sharply to its seat.

Objections to this valve are easy to find; the sudden return to its seat from a lift of three-quarters of an inch must make a noisy engine and at the same time have a destructive effect on the valve itself. It will be noted that during this return, at the end of the inlet stroke, the exhaust valve is momentarily opened.

Comparison of Worm and Bevel Drives—In view of the widespread use of the worm gear for final drive in place of the bevel on English cars, a comparison of the two systems in *The Automotor Journal* of January 1 has much of interest.

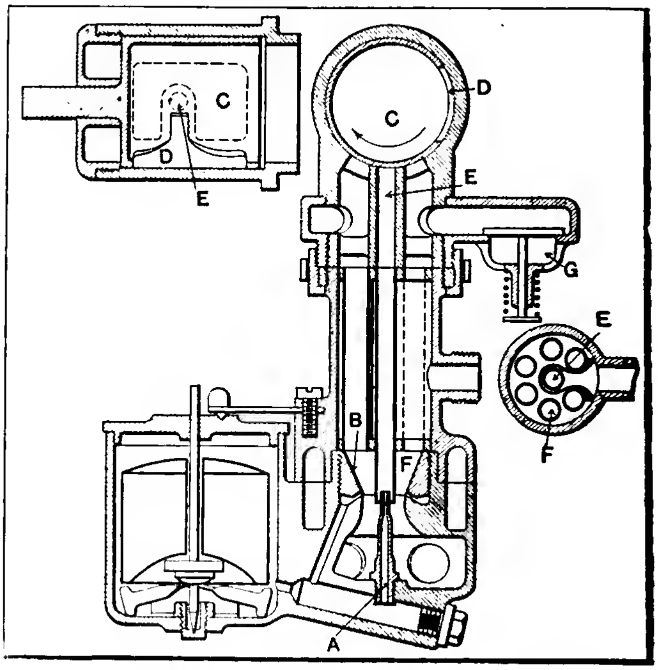
According to this paper, most manufacturers who have adopted the worm drive have done so because of its inherent quality of silence. The worm drive is by nature a more silent mechanism than the toothed bevel, because its method of transmitting power is absolutely continuous and of a sliding wedge-like kind. The bevel depends for its continuity of action on the accuracy of its manufacture, since, by nature, its operation consists of a sequence of blows. To an extent the worm and bevel may be compared, respectively, to the propeller and paddle-wheel in steamship propulsion.

From the purchaser's point of view, the relative efficiencies of the worm and tbe bevel are largely associated with the practical differences that are likely to be noticeable on the road. It is a common opinion expressed among those who have had experience with both types of car that the only noticeable difference between the two is to be observed under conditions of starting and coasting. A car fitted with a worm-driven axle would seem, in general, to convey the impression of a slight sluggishness, more particularly in not getting away so quickly from a standing start.

Proper lubrication is the secret of success with the worm drive. The worm, with its wedge-like sliding action, seems to have an especial propensity for squeezing the oil out from between the surfaces in contact.

English Multiple-Jet Carbureter—On the 12-16-horsepower F. L. car, recently introduced to the English market, there is incorporated a novel multiple-jet carbureter. A description of this device appears in the January 8 issue of *The Autocar.*

There are two carbureting chambers: the one formed by the tube E, which encircles the jet A and supplies the mixture at low speed; the other concentric with the first tube, and taking the form of a series of tubes F (sbown in plan in the small drawing), which draw gasoline from the auxiliary jets B. A rotary throttle C, formed with a carefully designed aperture D, uncovers the central tube E or the auxiliary tubes F in increasing proportion. An additional air valve G operates in correspondence with the motor speed. Wben the motor runs slowly, the whole of the mixture used passes up the central tube E, and it is therefore necessary that this tube be kept hot; this is accomplished by the admission of the exhaust gases to the spaces surrounding the jet chamber between the ring of tubes. The starting of the motor is made very easy, by the fact that, with the throttle in starting position, tbe central tube alone is open, and a strong suction is produced around the central jet.



Novel Design of F. L. Multiple-Jet Carbureter

FARMAN BROTHERS LEAD ALL FRANCE IN AVIATION

By W. F. Bradley.

PARIS, Jan. 20—When the old year rang out the Farman brothers remained the leaders in the aviation world, for Henry had definitely secured the Michelin trophy, and his younger brother, Maurice, had made the longest cross-country flight. The last week of the old year, however, was an anxious time for the holder of the Michelin record. On November 3 he had put up a distance of 138 miles in 4 hours 6 minutes 25 seconds, compared with 2 hours 20 minutes, by Wilbur Wright in 1908.

The most dangerous rivals were Edouard Chateau and G. Legagneux, both connected with the Voisin Company, and Hubert Latham, the managing director of the Antoinette factory. Fearing that they might snatch the trophy from him at the last moment, Farman had a machine specially prepared, carrying a load of nearly 30 gallons of gasoline, and ready to be taken out at a moment's notice.

Chateau was the first to make an attempt on a new type of Voisin, driven by a four-cylinder Voisin motor. On account of the large supply of gasoline carried it had been necessary to fix the tank low and secure a flow by means of pressure. After covering a short distance the tank burst and Chateau had to abandon. Legagneux, who was similarly equipped, had a backfire to the carbureter, which set his whole machine ablaze while in the air on a trial flight. As there were 25 gallons of gasoline on board the situation looked dangerous for a few moments, but Legagneaux managed to come to earth and have the flames extinguished without any serious damage to his person. Most of the lower plane was burned away, and the woodwork suffered so much that it was impossible to make another attempt on the last day of the year.

Latham remained as a menace to Henry Farman, and when he brought out his Antoinette on the last day of the year, the biplane champion gave orders also for his machine to be pushed onto the plain. The two started almost at the same time over the military ground near Mourmelon, Latham with the intention of beating the Farman record of 138 miles, and Farman with the determination to fly further and faster than his rival. It was a speed as well as an endurance test, for account is taken of distance covered round a triangular course, and not of the total time in the air. Farman employed all his skill, taking the turns short and in a masterly manner, while Latham, higher and more impressive, was in danger of being lapped by his opponent. The duel lasted for an hour, at the end of which time Latham was obliged to descend owing to his motor overheating.

Fearing that another attempt would be made to break the record, Farman continued to fly around the course alone. When he had been in the air 2 hours 24 minutes, and covered a distance of about 100 miles, he made a voluntary landing, for it was then too late in the day for any other aviator to beat the November record before the official hour of sunset.

Maurice Farman Flies to Orleans—While Henry Farman was flying at Mourmelon to retain the Michelin trophy, his brother Maurice was making an aerial trip from the town of Chartres, on the Beauce plains, to Orleans, in the Chateau country. The voyage was the continuation of one commenced at Buc, in the suburbs of Paris, a couple of weeks before. Farman had originally intended, after his descent on the town of Chartres, to continue by stages to Bordeaux, some 300 miles away. In view of the wintry weather, however, this was abandoned in favor of a trip to Orleans only.

The distance is about 47 miles, over fairly open country. The task was rendered difficult, however, by the start, which had to be made from very heavy ground. It was not until the frost had dried out the rain that a start could be made on the last day of the year. Rising to a height of 200 feet, Farman soon left in the rear his mechanics and friends endeavoring to follow him in fast automobiles. Fifty minutes later he had landed without a broken spar in an open field chosen in advance on the outskirts of the town of Orleans. The trip so successfully accomplished is a record for cross-country travel. The aeroplane employed by Farman is a biplane of his own design, but having a certain resemblance in its general features to the machine employed by his brother. The motor, which has always been used on this aeroplane, is an eight-cylinder, air-cooled Renault, on the camshaft of which is mounted a two-bladed wooden propeller, having a diameter of nearly 8 feet. Naturally the camshaft is specially strengthened, its diameter being equal to that of the crankshaft, while the timing gears have more resemblance to those employed in the gear box of a powerful touring car than to the usual fine construction.

Maurice Clement, the brother of the better-known Albert, killed a few years ago on a racing car at Dieppe, is now giving lessons in flying to Mlle. Helene Dutrieux, one of the first lady areonauts in France. The machine employed is the first of the "Demoiselle" monoplanes built in the Clement factory, under the supervision of Santos-Dumont. Although the general design has been retained, the new "Demoiselle" is a much more comfortable machine for its occupants than the model with which Santos-Dumont made his first flights. It has been raised higher from the ground by the use of larger wheels, and the pilot is comfortably housed below the wings in an automobile type of light aluminum bucket seat. The motor, too, is more powerful, being a four-cylinder Clement-Bayard of 40 horsepower.

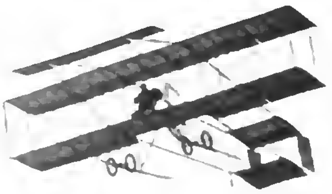
PARIS PLANS AERO AND AUTO SHOWS

Paris, Jan. 20—Paris has decided to hold its second annual aeronautical Salon in the Grand Palais in the Champs-Elysees, from Saturday, October 15, to Wednesday, November 2. The event will practically be a repetition on an enlarged scale of the first aero show, held in 1909. Uniform stands will be adopted, and although the event will be made as artistic as possible, money will not be wasted on mere decorations. The hall is so large that about one-third had to be boarded up for the first exhibition. Aeronautics, however, are developing at such a rate that doubtless the whole building will be occupied for the 1910 event.

Unlike the aero manufacturers, the automobile constructors are far from advanced in their preparations for the next automobile show. It is generally understood that an exhibition will be held, and that the Grand Palais will be occupied as on previous occasions, but absolutely nothing has yet been decided officially. The hall having been secured by the aero manufacturers until the first week in November, it will be necessary for the automobile men to hold their event later in the year, either towards the end of November, or, more likely, during the month of December.

TEN 'PLANES FOR PYRAMID AERO MEET

Paris, Jan. 20—One American and nine French aeroplanes will take part in the Egyptian races to be organized by the Aero Club of France from February 6 to 13. The American machine is a Curtiss biplane to be piloted by De Riemsdyk. Mortimer Singer, an American sportsman, will pilot a Farman biplane, with Arthur Duray, the well-known race driver, as his companion. Hubert Latham and Hanvette will have Antoinette monoplanes; Rougier, for a long time team-mate with Duray, will pilot a Voisin biplane together with Metrot and Mme. Delaroche, providing the latter recovers from an accident sufficiently early to earn her pilot's certificate; Le Blon and Jacques Balsan will each have a Bleriot monoplane. The races, the first of the year, are to be held on a specially prepared aerodrome established on the edge of the desert in the vicinity of Cairo.



PICTURE STORY OF THE LOS ANGELES MEET

Paulhan's First American Flight

Paulhen Inspecting His Seven-Cylinder Motor

LOS ANGELES, Jan. 22—Aviation week was concluded Thursday by a remarkable race between Paulhan and Curtiss, which, like the meet itself, resulted in divided honors. Paulhan went up at 3:25 in his Farman biplane for an endurance flight. After he had done two or three laps of the course, Curtiss started a ten-lap speed trial, half a lap, or more than three-quarters of a mile behind him. The two aeroplanes came over the grandstand at a fifty-mile clip, with Curtiss gaining rapidly. On the third lap the little American machine, high in the air, caught up with the big French one. For a few seconds Paulhan held even. Then Curtiss went over his head, at first for a single length, finally half a lap. Curtiss came down after a thirty-mile trip, but Paulhan continued flying for an hour and a half, covering 64.4 miles.

This one race summarizes the whole story of the meet. The Curtiss machines won all the prizes for speed, quick starts and perfect landings; Paulhan, on the other hand, won the cross-country, passenger-carrying and endurance tests. The latter broke world's records for altitude and cross country flights, both alone and with passengers. He will receive more than $15,000 in prizes. Curtiss made no records, and took about $5,000. Charles K. Hamilton and Charles H. Willard, of the Curtiss team, took second and third prizes in most of the events, never equalling the two masters.

Wednesday Paulhan took his wife for a twenty-mile spin out over the ocean. At 2:27, after helping Mrs. Paulhan into her seat behind him, he flew out in front of the grandstand, made his bow, at it were, and then set off toward the Pacific. In ten minutes he was out of sight among the sun-lit clouds. At an altitude of from 500 to 1,000 feet he passed over Redondo Beach, Venice-by-the-Sea and other resorts toward Point Firmin, for half a mile being directly over the ocean. At 2:50 he came in sight of the waiting crowd at the grandstand, and at 3 o'clock made his landing, whereupon he was carried in triumph down the lanes of frantic spectators.

Returning to his machine he began to run a sort of aerial omnibus, and within a short time took up five other passengers, the lucky ones being Mrs. Cortlandt F. Bishop, William Randolph Hearst, Clifford B. Harmon, Lieut. Paul Beck of the United States Army Signal Corps, and a newspaper reporter. Mr. Harmon got a twelve-mile trip, but the others had to content with shorter distances. Lieut. Beck on his trip tried to drop a dummy bomb from a considerable height into a measured square on the ground. He was not successful, but did not miss his mark by a very great margin.

Paulhan, with Maisson and Miscarol, his assistants, is now in San Francisco. It is probable that they will fly at Salt Lake City, Denver and New Orleans, at the last city during Mardi Gras. Beyond that they have no definite plans.

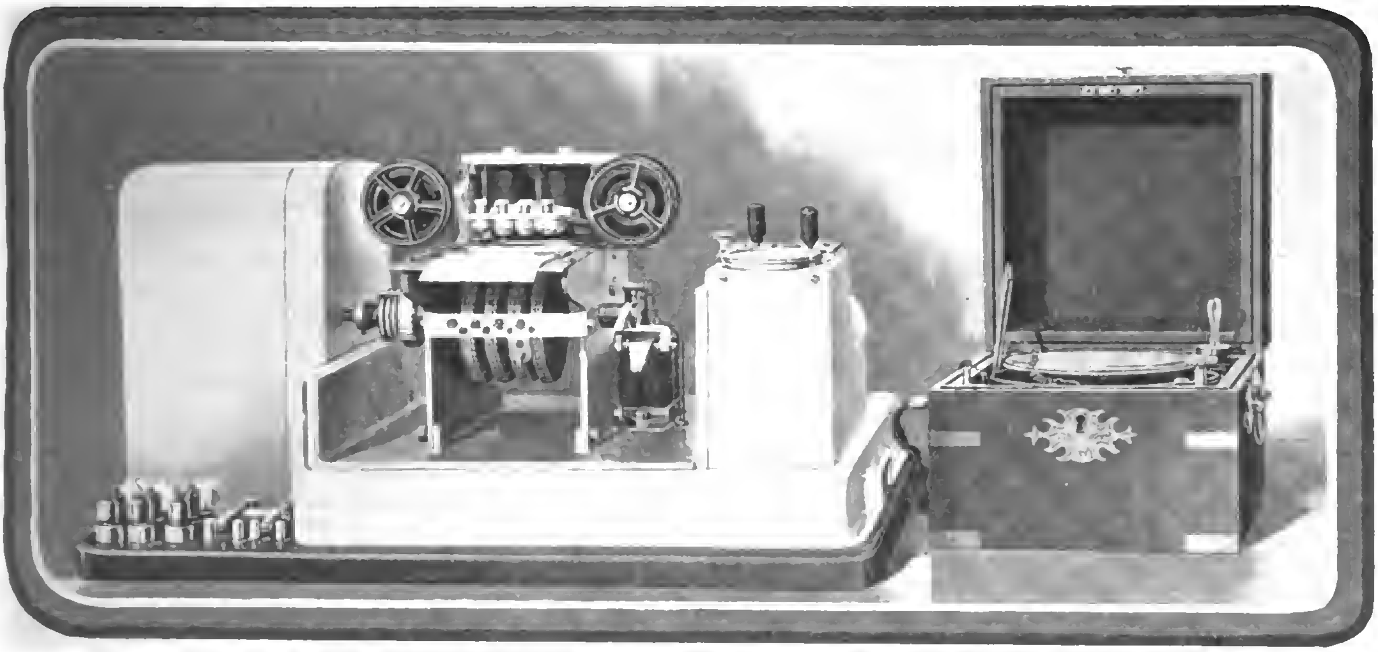
About to Leave the Ground, with Mrs. Paulhan as Passenger

Curtiss Passing the Grandstand Trying for Speed Record

HOW 1910 AUTOMOBILE RACES WILL BE TIMED

RACE-GOERS of the past season will be interested in the 1910 Warner timing instrument, which did such good service at all the principal race meets. The "horograph," as it is called by the maker, the Warner Instrument Company, has been redesigned and put in a more compact and workmanlike form, although the principles of its operation remain the same. In its original form the instrument recorded the times in tenths of seconds, which at the time was thought to be wonderful accuracy. The new "horograph," however, is far ahead of its predecessor, for it records the time in hundredths of a second.

The improved machine was given its tryout at Atlanta last November, and satisfied the most exacting critics. It makes dead heats almost impossible, as even when racers cross the line so close together that the eye alone cannot distinguish any difference, the machine will still find that one or two hundredths of a second separated them. One such case actually took place at Atlanta, where a ten-mile race was decided by 1-100 second at the finish. Some idea of the accuracy obtained may be gained from the fact that a car going a mile a minute goes 10 1-2 inches in 1-100 second.



Warner "Horogrsph," Which Distinguished Itself at Atlanta, Timing Racers to the Hundredth of a Second

THE AUTOMOBILE CALENDAR

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Jan. 24-31........Washington, D. C., Convention Hall, Automobile and Aeronautical Show, Automobile Dealers of Washington. B. R. Johnson, Manager, 1313 New York avenue, N. W.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main street.

Feb. 14-19........St. Louis, First Regiment Armory, Fourth Annual Automobile Show, St. Louis Automobile Manufacturers' and Dealers' Association, Robert E. Lee, Manager, 1629 Washington avenue.

Feb. 14-19........Rochester, N. Y., Convention Hall. Third Annual Show, Rochester Automobile Dealers' Association. Captain C. A. Simmons, Manager.

Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South street.

Feb. 19-26........Cleveland, Central Armory, Annual Automobile Show under auspices of the Cleveland Automobile Show Company. H. M. Adams, Secretary.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-26........Baltimore, Second Annual Automobile Show of the Automobile Club of Maryland, Fifth Regiment Armory.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Sec.

Mar. 5-12.........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park square.

Mar. 12-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden,, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

April 23-29.......Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

Races, Hill Climbs, Etc.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

DETROIT ENJOYING A GENERAL REVIEW

The Detroit show is interesting from two points of view. It is convened in the city of the West which supports 25 makers of automobiles, and the car production in Detroit for this year is estimated at 20,000 more automobiles than were made in all the world last year. Measured in automobiles, last year the world was large, ever so large, but the City of Detroit, where the "natives" say, "life is worth living," has lifted itself by its bootstraps, as it were, and in the doing made it possible to say, as a figure of speech, "a part is larger than the whole." Of the 43 makers of automobiles in Michigan, many of the balance, after deducting 25 in Detroit, are within a short trolley ride of the Pontchartrain, and counting this number of plants as substantially in, or clustered around Detroit, it is something to say that 50 per cent. of all the automobiles made come from this district within a trolley ride of Detroit.

This phase of the automobile industry is probably a little more than half of the whole, but by no means all. Besides the 43 makers of automobiles which center around Detroit, there are accessory plants, tire makers, and body manufacturers, which concerns, while they supply parts to Detroit makers of automobiles, also have a vast trade in 24 States of the Union in which automobiles are made, ranging from a valuation of $200,000,000 per annum in Michigan down to $5,000 in Georgia. It would be a little unfair to Flint, Michigan, to thus give to Detroit the palm—Flint produces nearly $80,000,000 of value in automobiles per annum, taking this year as the basis, and more than $30,000,000 in value comes from Lansing, Pontiac, Jackson and nearby towns. Were this the end it might be worth while to comment on the growth of the industry, but it is scarcely a good beginning and none will dare attempt to fix the boundaries.

ENGLAND GAINING FOREIGN LEAD

Students of the foreign automobile situation cannot fail to be impressed by the remarkable progress made during the past few years by England, as compared with France, Germany and Italy. If the present rate of advance is maintained, another twelvemonth will find the "tight little isle" comfortably in control of the foreign trade. English makers, long submissive to the dictates of Continental fashion, have of late developed an aggressiveness of spirit which has reacted both in the up-to-the-minute design of their cars and in their organizations.

The adoption of the Knight slide-valve system was the first important move. Although this has failed to "revolutionize the industry," it has been retained by all the companies originally using it. But as though this were not sufficient to prove the emancipation, several makers brought out other forms of slide and rotary valves.

The location of the radiator on the dashboard has also found many new adherents. This is logical in view of the spread of thermo-siphon cooling. The dashboard position allows the radiator to be set higher, consequently with a better head of water for the circulation, without marring the looks of the car.

In running gears there have been three important developments: worm drive, front-wheel brakes, and wire wheels. The last are now well-nigh universal in England, and are rapidly being taken up on the Continent.

GOVERNING DEVICES INCREASE SAFETY

While not perhaps as applicable to pleasure cars as to the more prosaic motor trucks, which are fast taking up the horse's burden, the use of any device in the nature of a governor is highly commendable.

As used today in this country these take many forms; one type utilizes the centrifugal action of balls at the outer end of rotating arms to decrease the volume of mixture, or retard the spark; another uses water or other fluid pressure upon a flexible diaphragm, which acts upon the throttle or spark, as the case may be; still others employ other principles of tried and proven merit to restrict the speed of the engine, and thus the speed of the vehicle, to a certain predetermined maximum. This is a quantity which the manufacturer is able to fix, and in so doing, serve the best interests of his clients, as well as himself.

However, many a purchaser loses sight of the fact that this very problem of maximum speed may have been carried throughout the entire design, and that in so altering the machine as to render the governing device futile and useless for the sake of a mile or two more per hour, he is really only paving the way for the quicker destruction of his vehicle. The net result will be a saving throughout the vehicle in upkeep and repair costs, as well as a marked decrease in the fuel and oil bills.

M. C. B. AND THE AUTOMOBILE INDUSTRY

It is well within the memory of many who are now in the automobile business, when railroads were absolutely free from any restraint from the point of view of standard methods. Master car builders (M. C. B.) if they met at all, failed to appreciate the advantages of a standard gauge, crystallized methods of design, and materials of a known desirable composition.

Those of our citizens who object to combinations, as they say, in restraint of trade, have but to slip back to the old and heterogeneous methods of non-standard work, and law will be wholly unnecessary, a combination will be impossible. As a matter of fact all the law in the universe would fail in the face of a 60-inch tread of car wheels on a 54-inch track, nor is this a far-fetched illustration of the variations which obtained but a few years back in railroad work.

History, if it repeats itself, is retarded in its march by the inertia of intelligence, or better yet, by lack of appreciation of known facts. It is a known fact that a standardized method of doing anything is better than a haphazard jump in the dark. Christopher Columbus discovered America against his inclinations; he was looking for India. Had he followed the standarized methods of to-day he would not have been disappointed.

Napoleon Bonaparte, at Waterloo, lost to Wellington, as history relates, because he departed from a standard. The peasant guide who affirmed that the way was level and the going good, did not represent the standard of military intelligence which Napoleon usually relied upon.

I-sections in structural shapes were long ago standardized—why should they not be brought under the same mantle of intelligence when they are employed in automobiles for front axles? The distance between supports is the same in all; roads are no better for one than another; shock is the same for all; a given grade of material is not improved by a difference in the color of the paint, and, when the last word is said, the desire of a designer to be different does not make him right.

Life of tires must be the desire of every autoist. This life is scarcely to be measured in terms depending upon a given size of tire, of a given make, for a given weight of automobiles. Weight alone is not the criterion. If two automobiles weigh the same and one of them is capable of traveling faster than the other, it is morally certain that the tires (of the same size) placed upon the more speedy automobile, will give out much the sooner.

Horsepower rating of a motor is not merely dependent upon the piston displacement under given conditions of compression, considering a given fuel. Rule-of-thumb formula is like "dog French"; were one to inquire for bread in dog French from passersby in Paris he would probably have to fast—adapt the standard and all will be well.

Radiators, of a given make and size, are not likely to work equally well on two different designs of motors. This is due to an entire absence of any standard method of fixing the flame-swept surface in proportion to the compression, piston displacement, etc. A steaming radiator is a most pronounced indication of the lack of a standard.

LICENSED AUTOMOBILE DEALERS ORGANIZE

While nothing was said to so indicate, it was generally understood that the new management of the Association of Licensed Automobile Manufacturers was responsible for the meeting of the New York dealers in licensed cars, held at the Hotel Astor last Thursday afternoon.

Over 20 local dealers responded to the invitation which had been sent out. The meeting was called to order by Sidney B. Bowman, who explained the objects and purposes of the proposed organization. Mr. Bowman's remarks met with the hearty approval of those present and it was decided that an organization should be perfected to include only such dealers as handle cars licensed under the Selden patent.

Percy Owen, of the Carl Page Company, agent for the Chalmers-Detroit, was elected temporary chairman and Mr. Bowman was made temporary secretary. It was decided to form an organization committee to consist of five members, who would also act as nominating committee. The chairman was given power to name this committee and stated that he would do so in the course of two or three days.

The new organization practically means the end of the New York Automobile Trade Association, which has been in existence for several years, as all of the members of the latter body were represented at the Hotel Astor meeting with the exception of four firms. One of the officers of the New York Automobile Trade Association practically admitted that the new organization will undoubtedly replace the older body.

If, as it is said, the A. L. A. M. was responsible for the calling of this meeting, it indicates an entire change of policy from that which was adopted by George Day, the organizer of the Licensed Association. During his connection with that organization Mr. Day discouraged in every possible way the formation of local bodies of licensed dealers undoubtedly under the belief that the individuals would be more easily controlled than organized bodies.

It is understood that one of the purposes of the new organization will be to conduct a campaign of education among the prospective buyers of cars, drawing attention to the Selden patent and the alleged liability of suit to those who purchased unlicensed cars.

Among those present at the Hotel Astor meeting were:

Sidney B. Bowman, George Johns, Col. K. C. Pardee, C. A. Duerr, Gen. John T. Cutting, J. Joyce, Carl Page, Percy Owen, Charles A. Singer, Jr., George W. Bennett, John F. Plummer, Fred Titus, W. H. Hurlburt, I. N. Uppercue, C. W. Wurster, E. Day, Robert Slusser, Ferdinand Cimiotti.

INTRICATE PROBLEMS INVOLVED IN SELLING

With an increase of 130 per cent. in the production of cars during 1909 over 1908, taking the licensed situation alone, it is necessary to seriously consider one or two of the phases among which the question of the future disposition of second-hand (used) automobiles is bound to float to the top. It has long been the practice of the selling representatives for the various makers, to take in trade used cars of their own make and allow something for them on account of the new purchase. That they will continue to do something of this kind is very likely, and it is even possible to foresee that it may be advantageous to any maker of automobiles to father the used cars of his brand rather than to allow them to become as "flotsam and jetsam," kicking about under the heels of the buying public, offering false ear marks which will reflect seriously upon the quality of all automobiles of the same make.

One way which has been suggested by a very fair-minded builder of automobiles is to organize a series of repair shops and more or less supervise their operation, placing the used automobiles in hand for repair and permitting the repair shops to realize a profit consistent with the troublesome work.

Waverley Electric Roadster

Fig. 1—Knife edge revolving controller as used on Waverley electrics in conjunction with Type H motor

GRADUALLY the general appearance of all mechanical modes of transportation verges towards a common standard, and the chances are that in the long run they will all look very much alike, if, indeed, agreeably to locomotive practice, they may not all be substantially the same, unless, perchance, there may be some four or five separate schools of design, each one persisting in some one method.

The new Waverley electric roadster, as it is offered this year, is interesting from the point of view of standardization, as well as to the patrons who prefer an electric vehicle to a gasoline automobile. That there should be just such preferences is to be readily taken for granted, due to the splendid utility of electrics, despite the greater radius of action of gasoline equipment.

BATTERY IN FRONT UNDER THE BONNET

The Exide battery, of 32 cells, each with 11 plates, is placed under the bonnet in front, just as the motor is there placed in gasoline work. It is something of an advantage, according to the maker, to thus have the battery in a perfectly accessible position, due to the facility with which the cells may be examined, the specific gravity of the electrolyte taken, and if necessary, remove the battery for the purpose of making repairs.

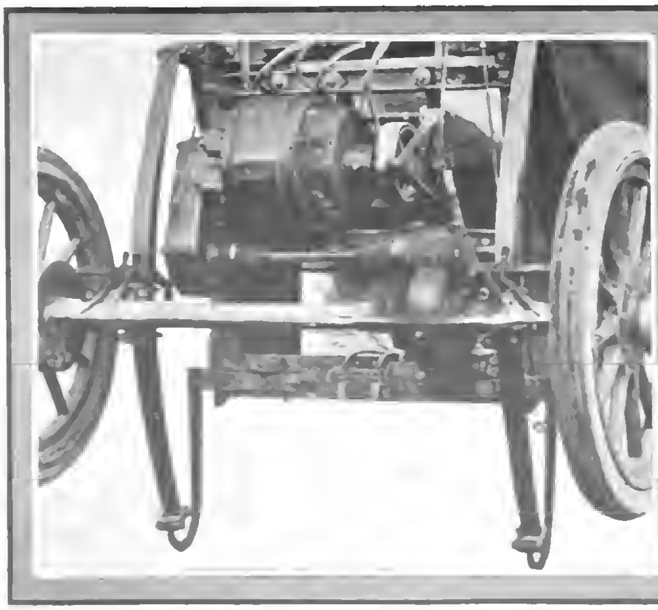

Fig. 2—Detecting relations in the swing of the power plant to the rear axle

The body of the chassis is 108 inches long, with a wheelbase of 94 inches, and the tread is 54 inches. The body is commodious, with inside measurement of the seat of 38 inches; the color is gray. A tilted steering wheel of the irreversible type, brings this part of the vehicle up to standard automobile practice, while the motor suspension is that usual in Waverley practice, as depicted in Fig. 2. This suspension has served for some time in the several types of vehicles of this make, and, besides being noiseless it has the faculty of delivering the power with a minimum loss as the characteristic Fig. 3 adequately indicates.

TYPE "D" CONTROLLER FOR CONTINUOUS TORQUE

In order to limit "drop" in the controller, thus safeguarding the commercial efficiency of the whole equipment to a considerable extent, the controller is so made that the "wipe" principle of contact assures high electrical conductivity across the joints. This is accomplished by having a central revolving core upon which is mounted a series of properly contoured knife-blade members which press between contact pieces which, in turn, are formed out of suitable grades of copper in sheet or strip form, securely fastened and held in rigid relation so that the knife blades pass between each pair of the fixed members and pry them apart sufficiently far to enable the core to rotate and make the respective combinations.

The "make and break" system of control is adopted in this system; the idea represented is to maintain a constant state of torque during the period of acceleration of the vehicle—just when torque is most in need. The controller is contrived to give four forward, and as many speeds in reverse, but in order to assure safety in the hands of the least experienced, an interlocking device is applied with advantages as follows:

(a) Direction cannot be changed while the power is on.
(b) The vehicle cannot be started in either direction, unless the lever is at the neutral point.

The controller is compact, well designed to stand the continuous working, and the connections of the wires from the motor and battery are so securely made that they will neither come loose or impose a high resistance to the electrical current. The wiring system is also most carefully executed, large sizes of wire are used to limit "drop," that is, the loss of voltage in the wiring is reduced to a nominal point by the proper grading of the sizes of wires used in the several branches. The wiring is also accessible, which is a point of importance, and too, the insulation is acid resisting, and so placed that the fumes from the battery cannot contact with the wiring.

TEST SHOWS ECONOMICAL CONDITIONS

It is of the greatest importance to conserve the energy in the battery for two reasons:

(a) The radius of travel of the automobile will be so much the greater.

(b) Life of the battery will be augmented: the life of any battery is in direct proportion to the number of discharges to which it will be subjected under a fixed set of conditions.

The curve, Fig. 3, was taken expressly for THE AUTOMOBILE in order to permit of a definite statement of the relating facts, it being the idea to display a proper regard for truth in discussing a matter of such great importance. In this chart the current in amperes is written as ordinates, and abscissa are given in four figures in order to express all the conditions.

A careful study of this chart will disclose divers points well worth knowing in relation to electric motors as they are applied to automobile work, as for illustration, it will be seen that the curve of efficiency is almost flat top between 20 and 120 amperes of current; it raises from 20 to a maximum at 35 amperes, but at 120 amperes the efficiency is no lower than at 20 amperes of current intake of the motor.

The speed of the motor is maximum at minimum load, which is to be expected since the motor is series wound, and, as to the speed variations, they range from 1,640 at 33 amperes, which is the point of maximum efficiency of the motor, down to 400 revolutions per minute when the load is such as to draw 120 amperes of current from the battery.

Referring to the torque, it is 74 at 120 amperes and 22 at 60 amperes of current, this curve of torque proves to be particularly desirable for work of this character, it being true, as a rule, that power of electric motors is a rapidly falling quantity as the load increases beyond a certain point.

The speed of the car in miles per hour, changes as the load increases, which is true when a car is required to make a grade or if the road is not hard and level. All motors do not perform in like manner in this regard, and, as to this particular motor the performance is plotted in the curve to show result as follows:

RELATION OF SPEED TO CURRENT IN AMPERES

Current in amperes.	Speed in miles per hour.
20	30.8
30	23.8
40	18.6
50	15.0
60	12.6
70	11.0
80	9.8
90	7.8
100	5.9

This interpretation of the chart as it tells about speed of the car for current consumption, is the real story of the efficiency of the whole, and, as an inspection will disclose, the speed falls to about 1-6 of the initial speed while the current in amperes increases in the ratio of 1:5. There is one other point which will tell of the mechanical efficiency of the whole; the curve of speed in miles per hour, while it shows a falling off as the load is increased for any cause, sustains to a remarkable degree, and fails to recede enough under increasing load to allow criticism.

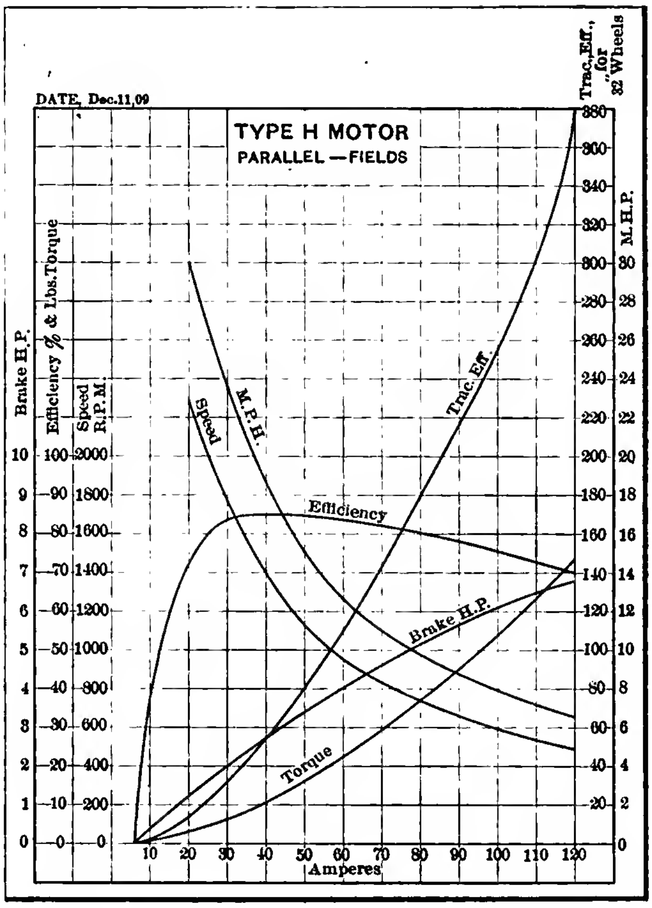

Fig. 3—Curve of performance of Type H Waverley motor, depicting a fine relation of torque to current in amperes

Were the motor inefficient at all speeds, which does not happen to be true, one would be inclined to look for high fixed losses. These fixed losses would be due to friction, hysteresis losses in the armature core, focault currents, possible in the polar horns, and to heat losses from all possible causes. A well-balanced motor is what is desired, in which the I^2R losses must also be carefully limited—this characteristic, as presented in the curve, is of just such a well-balanced motor.

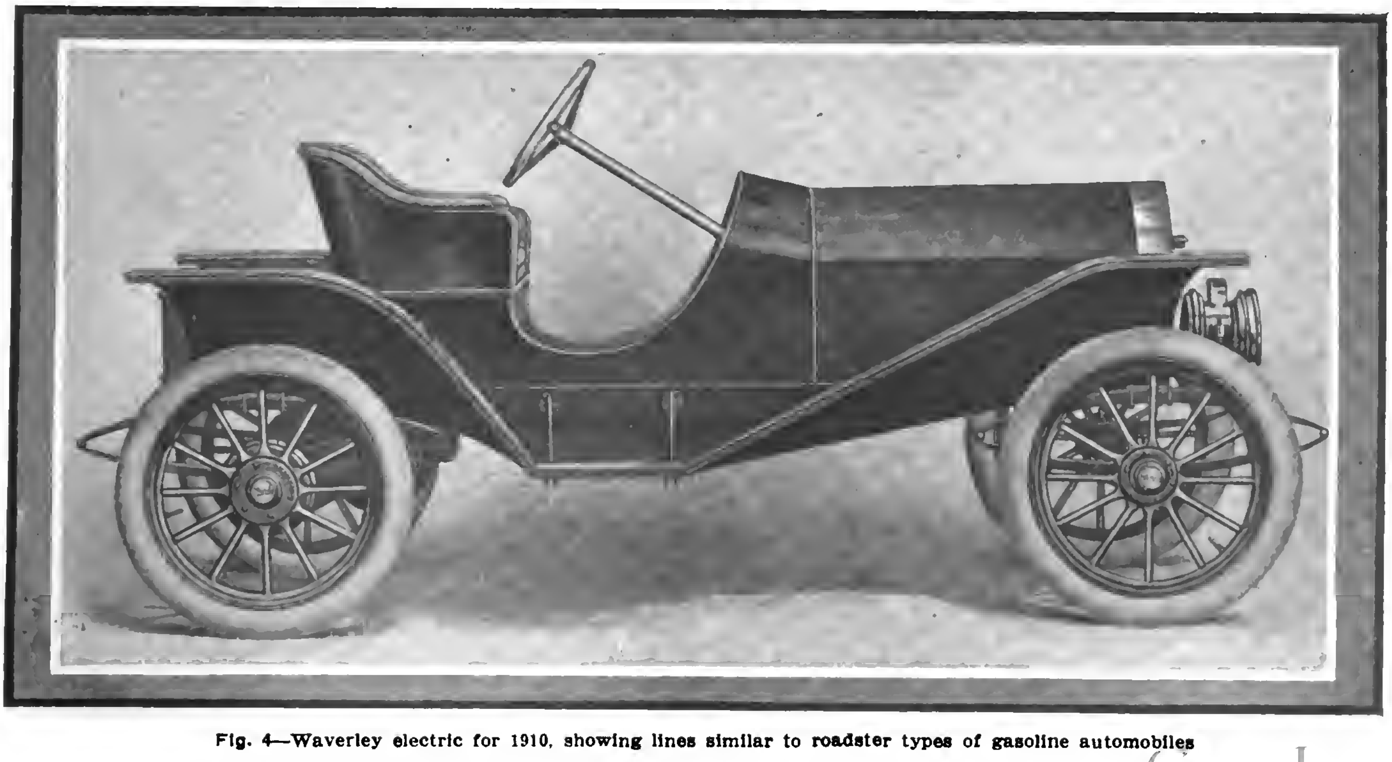

Fig. 4—Waverley electric for 1910, showing lines similar to roadster types of gasoline automobiles

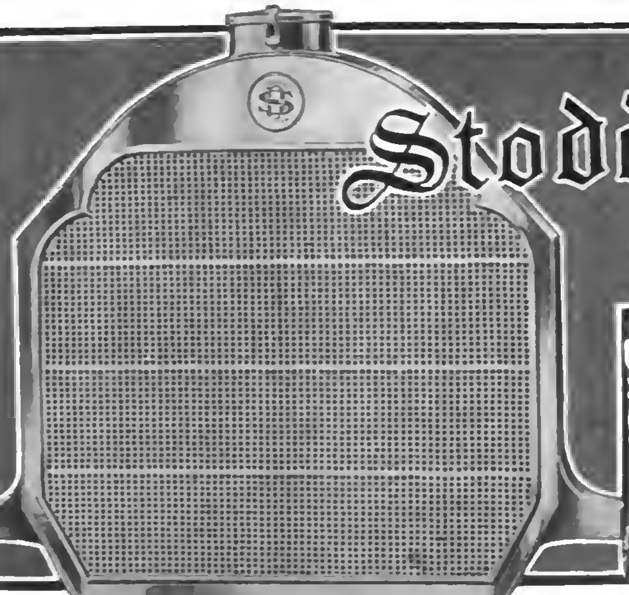
Stoddard-Dayton 1910 Construction



Appearance of 1910 Stoddard-Dayton Radiators

INFINITESIMAL would characterize the changes which have been made in the Stoddard-Dayton cars by the makers, the Dayton Motor Car Company, Dayton, Ohio, to fit them for the season of 1910. All told the line includes seven different chassis, which are powered by three distinct sizes of engine. Throughout the 1910 line, compared with the same cars as they were equipped in the past season, a longer wheelbase and more power are found to affect each and every model. To be specific, the three engines are rated by the makers at 30, 40 and 50 horsepower, respectively. The wheelbase of the 30 horsepower car is 108 inches in all models. The 40 horsepower types, on the other hand, all have a wheelbase of 116 inches. Then, with the still higher powered engine, a further increase is noted to 120 inches except in the 7-passenger touring body, the limousine, and landaulet enclosed cars, where the figure reached becomes 128 inches. The latest addition to the line is a speed car of 60 horsepower, which chassis has a short wheelbase of 106 inches. In addition to these, a town car will be put out, using the 30-horsepower chassis with 108-inch wheelbase.

Overhead Valve Arrangement Retained—Noticeable first in looking at the engine views is the retention of the overhead valves. This position, in combination with a spherical combustion chamber, is said by the makers to give a superior power output from any given size of cylinder. The valve marked A is the inlet valve, while B shows the exhaust. The position of the pipes gives a clue to the identity of the various valves, although the same could not be said of the push rods, for, with this motor, the exhaust camshaft is located on the inlet side, and the inlet camshaft on the exhaust side. So, it is that C, which is apparently the inlet push rod, is actually the push rod mechanism for the exhaust valve on the opposite side of the engine. An end view would show this construction, the rocker arms above, which operate the valves, and which are themselves operated by the push rods, cross one another above the cylinders.

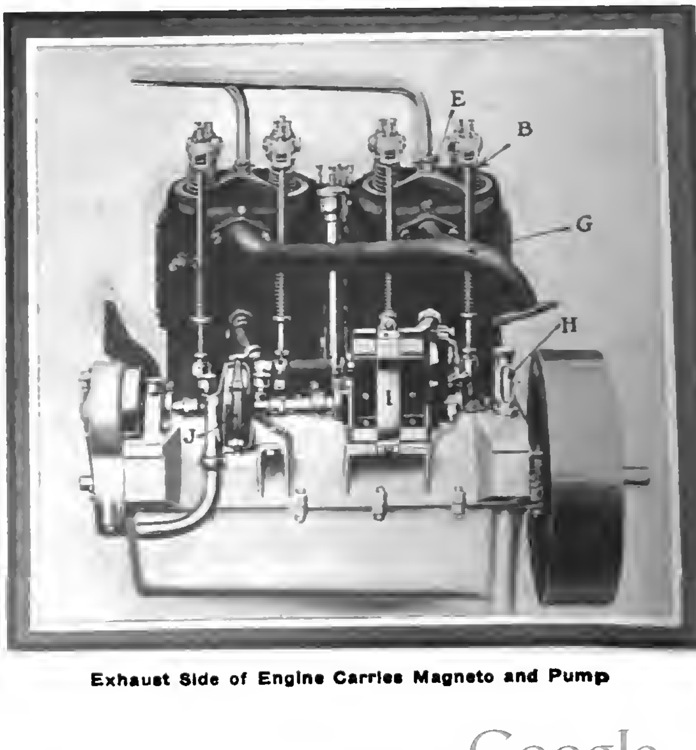
In looking at these two views of the engine, the method of fastening the valve cages in place will be noticed. This is a screwed-in fitting for the cooler and less liable to distort inlet valve cap, while the other, the exhaust valve cage, is held in place by a yoke. These yokes, marked E, hold each, a pair of valve cages, the loosening of a single nut sufficing to loosen and allow removal of a pair of cages. Since the exhaust valve requires grinding in more often than the inlet, this feature is one that will appeal to the experienced motorist.

In position, the valves are neither vertical nor at the more usual angle of 90 deg., being set at a very slight angle approximating 35 deg The use of the two valves in separate cages overhead, makes it necessary to place the spark plugs in the side of the cylinder casting. While not the exact center of the combustion chamber, this position is a very accessible one. One of these will be noted at D. The priming cups, and compression relief cocks are also placed in the side of the cylinder casting, and are visible in the same view, being located in pairs very close together, which is very convenient in priming, as two can be operated with practically one motion of the hand.

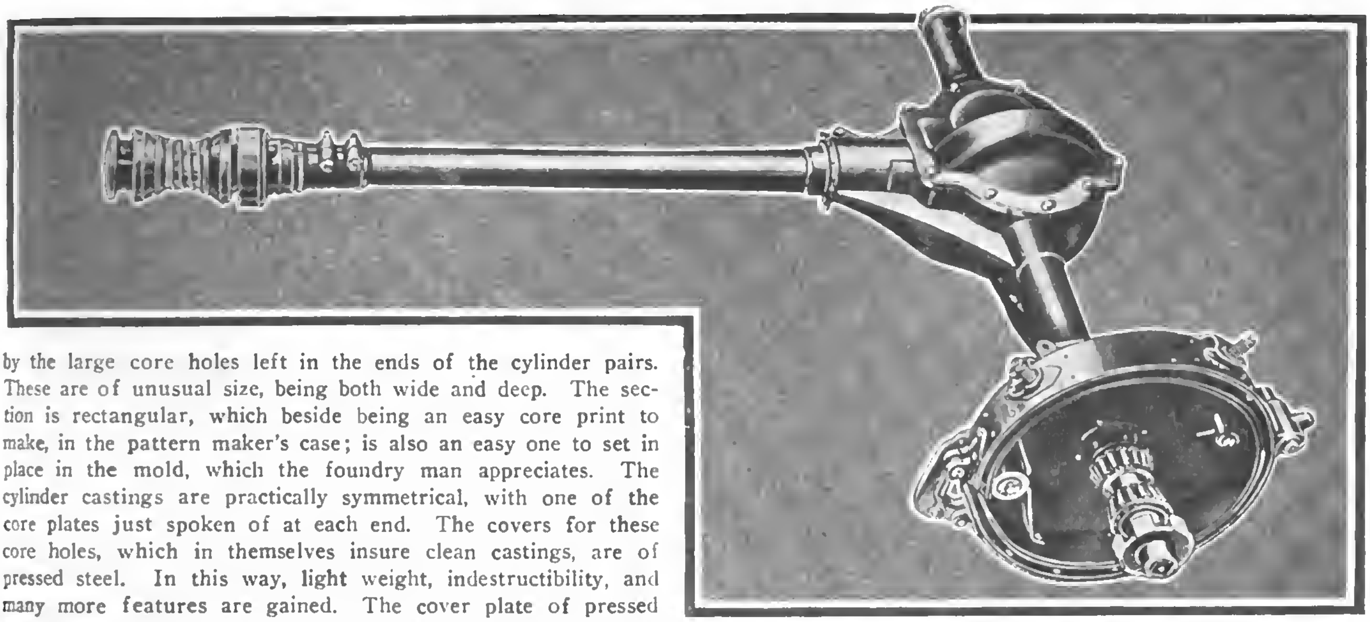
Tapering Pipes Make for Easy Gas and Water Flow—It is in the attention paid to little, but important, details, which shows the desire of a maker to improve his product, and in this particular case, several tendencies of this sort may be remarked about without harm. Thus, a glance at the exhaust side of the motor will suffice to show the tapered water pipe, which allows the two converging streams of outflowing water plenty of room. This is effected by an expansion of the diameter of the pipe just before the point of convergence of the two streams, that is, just before the first cylinder is reached, as shown at F.

This same side of the motor shows a similar scheme carried out on the exhaust pipe, which is exhibited at G. Without a doubt, the latter is of equal importance with the former, for the quicker the cylinders are cleared of the burned and thus, useless gases, the greater will be the power development. The pipe expands to a larger diameter just ahead of the second cylinder pairs—for this is the way they are cast. The short length of expanded diameter ahead of the second pair should have a muffling effect on the waste gases from cylinders one and two. This exhaust pipe is bolted up in place by means of a flanged connection, two bolts per flange being used. This allows of removing the pipe in its entirety without touching anything else, and with very little work or fuss.

Cylinders Cast in Pairs with Large Core Plates—The convenience of the foundry is taken care of in a suitable manner,



Exhaust Side of Engine Carries Magneto and Pump

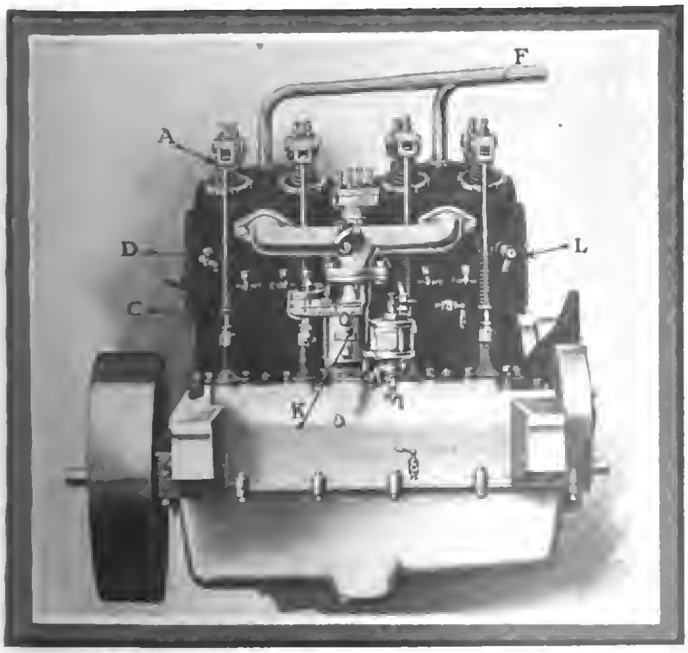


Construction of Stoddard-Dayton Rear Axle and Torque Rod

by the large core holes left in the ends of the cylinder pairs. These are of unusual size, being both wide and deep. The section is rectangular, which beside being an easy core print to make, in the pattern maker's case; is also an easy one to set in place in the mold, which the foundry man appreciates. The cylinder castings are practically symmetrical, with one of the core plates just spoken of at each end. The covers for these core holes, which in themselves insure clean castings, are of pressed steel. In this way, light weight, indestructibility, and many more features are gained. The cover plate of pressed steel is marked L in the picture, and is held in place by a goodly number of small diameter button-head cap screws, with a gasket below for water-tightness.

Aluminum is the material of the crankcase and covers. The case is parted laterally along the center line, forming an upper and a lower half, which are bolted together. The lower carries the oil well (variously called sump, compartment, and oil pan), and is of simple yet rigid shape. The upper half, on the other hand, supporting as it does all of the accessories, is necessarily more work for the foundry. The supporting arms, four in number, two on each side, are of a box shape, a small internal opening being left for lightness' sake. A pad for the pump support, and a small shelf for the magneto's resting place are found on the left side of the upper half, while the front end carries the inner, deeper half of the gear case. This reduces the cover for the gears to a simple plate, of nearly clypeate form held by eleven bolts. The single projection through this plate is the starting crank, which is surrounded by a packing nut or gland, threaded into the case. There is, then, nothing to oppose the work of removing the cover, for inspection or repair.

Carbureter Very Accessible, Too—The gears, valves, pipes and other parts, which have been described are not alone in possessing the desirable quality of accessibility, for the carbureter is a part which has had a maximum of consideration in this line. It is of the separate float chamber, Venturi tube type, with an auxiliary air adjustment. The float chamber has a glass body, which permits one to watch the action within and ascertain if the vaporization is proceeding properly. One innovation is the location of the throttle valve. This, instead of being an integral part of the carbureter, is carried up higher and fills the space at the parting of the inlet pipes, the nearest to the cylinders, which it would be possible to have it. After passing through the throttle, then, the carburetted air has a straight passage to the cylinder pairs. Moreover, the inlet pipe, is as short and compact as possible. The removal of two bolts, and the severance of the gasoline line—fitted with a union for this purpose—allows of the whole vaporizer being picked out bodily.

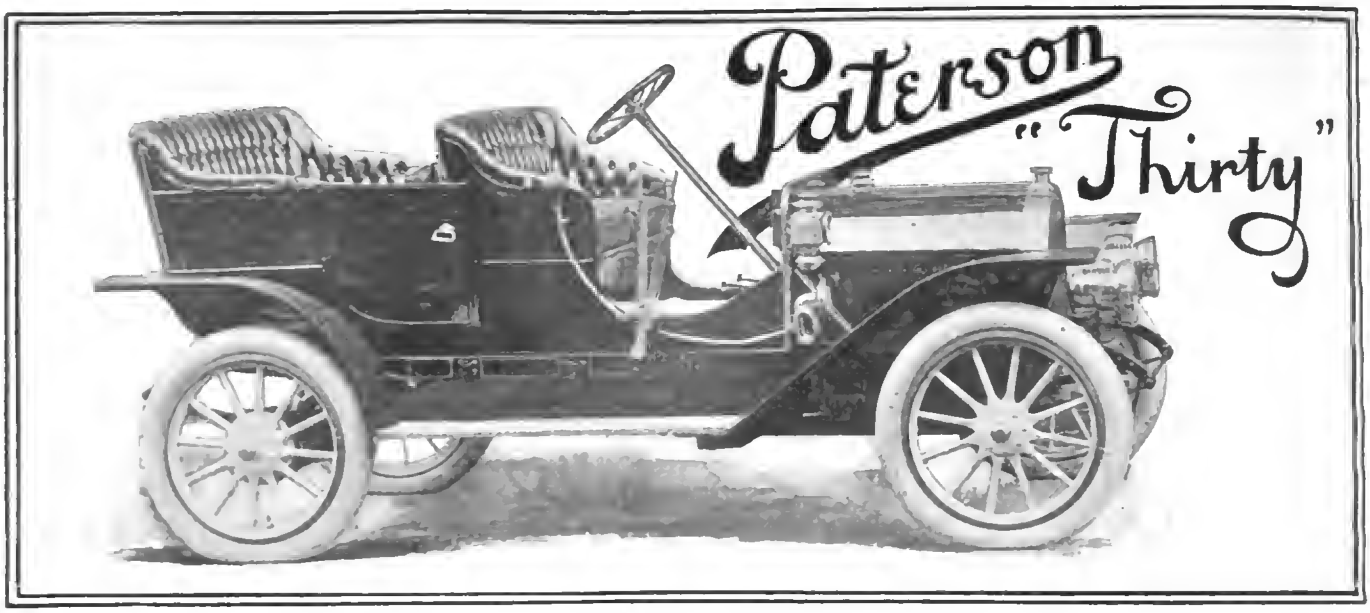


Inlet Side of Engine Reveals Carbureter

The magneto, too, is fixed up in a similar manner. The drive is through an universal coupling (with a shearing member, by the way), and is held to the case by a strap. Loosening this strap, disconnecting the wires, and pulling the magneto out backward, so as to separate the two component parts of the universal coupling, and the current system is ready for inspection.

Forward of this, and on the same side of the engine, is the pump of the centrifugal type. This, too, is driven by a shaft in which is located a universal coupling to allow ready removal. The water piping might be accurately described as "short and sweet," for there is but one straight, short horizontal pipe from radiator to pump intake. From the outlet above and on the cylinder side the discharge flows through a Y-shaped pipe with one branch somewhat elongated. Hose connections are used freely, but this is desirable as it makes for removability. The pipe from the radiator is free from the bends which set up much internal surface friction, hence the water flows easily. the friction component being small.

Speaking of radiator, this shows one of the few changes of the whole car. Whereas formerly of the tubular type, it now has the more popular cellular form. The shape, however, is unchanged, while the same might be said of the filling cap. The latter with characteristic Stoddard-Dayton accessibility written all over it, has been freely copied, being of a long, narrow, common-sense shape, which allows one to pour into it directly from any kind of a pail, without first hunting up a funnel. The fastening for the radiator cap is good, also. Being hinged at the back, it is only necessary to hold the front edge down. This is done by means of a crooked lever, which is spring held in an upright position. To open, the lever is pulled forward past the center of the spring-holding device, when the force of the spring acts to hold it down.



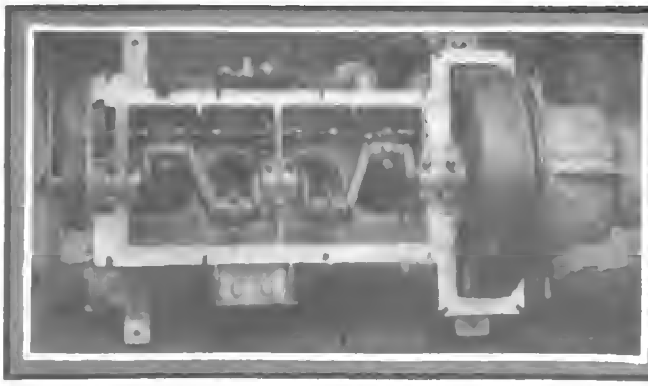
Full Side View of the Moderate-Priced Paterson Thirty Shows Excellent Proportioning of Parts

SPECIALIZATION marks the attack upon the present automobile situation of the W. A. Paterson Company, Flint, Mich., which concern is bringing out for the approval of America's shrewdest buyers, a machine which will be in the so-called $1,500 class. A single thought will suffice to show that this specialization is wise, for the class entered is well filled with a representative lot of cars from a very active group of manufacturers. At the price set, $1,400, and in view of the worth of the car, as it will be described herewith, it is apparent that the proper share of the business will come the way of the makers of the Paterson "30."

In specializing upon this one chassis, the maker is able to give his undivided attention and that of his entire factory personnel to this one unit, its perfection, refinement, production on specified time, and many other items which, small at first glance, loom up large in the long run. For the differing tastes of differing personalities, three distinct bodies will be fitted to the one chassis, a five-passenger touring car, demi-tonneau and tourabout. The price of this model with either the touring car or demi-tonneau body is $1,400, while the tourabout sells for $1,285. The equipment includes the full set of lamps with generator, magneto, robe and foot rails.

From the cuts of the power plant and chassis herewith shown, one will at once see that the aim of the Paterson Company in designing this car was simplicity, compactness, and at the same time, to make this car one of high efficiency.

Details of the Unit Power Plant—The motor, clutch and transmission form a single unit, and all working parts are enclosed in a single case which thoroughly protects it from dust. This construction is the best and most up to date for small and medium-sized power plants. It eliminates all possibility of parts getting out of alignment through road shocks, etc. This entire power plant rests on a pressed steel subframe and can be removed by simply taking out four bolts.



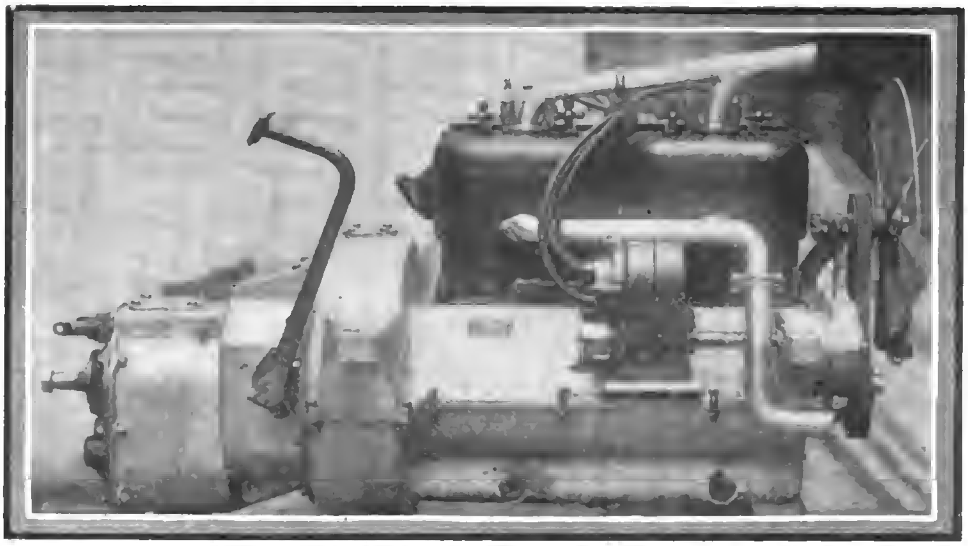
Crankcase Viewed from Below with Cover Removed

What the Motor Shows—The cylinders are cast in pairs made of close gray iron and finished by grinding to assure accuracy. The pistons are ground to size and fitted with three rings ground on sides to fit the grooves in the pistons. Valve heads are of nickel steel with carbon steel stems and ground to size; valves, which are adjustable, are large and located all on one side. Valve ports, through which the valves are removable for grinding, are closed by screwed-in plugs, those over the inlet valves being threaded internally for the spark plugs. The connecting rods are drop forgings, crankshaft bearings and connecting rod bearings are made in two halves and are easy to adjust. The crankshaft is a heat-treated, open-hearth carbon steel drop-forging; bearing surfaces are ground. Both the crankshaft and the camshaft are carried in three bearings and are supported by the upper half of the case.

Elsewhere on this page will be found a picture showing this. It is a view of the engine from below, with the lower half of the crankcase removed. The shape and comparative size of the crankshaft parts are to be clearly seen, as are also the length of the three bearings provided. This view reveals, in addition, the shape of the crankcase at the line of division of the upper and lower halves, which is, as usual, at the center line, and in a horizontal plane. The gears are set into the part of the gear cover which is integral with the front of the case. This makes an accessible and convenient arrangement, for the cover is then but a flat plate, easily and quickly removed.

The housing for the flywheel, too, may be discerned, as well as the four bolt holes, the occupants of which retain the upper and lower halves of the same in juxtaposition, and retain the lubricant within where it is useful, instead of allowing it to slowly leak out, where it is of no use. Each of the three crankshaft bearings is provided with four bolts of large diameter, which bolts are removable and, the reverse, insertable, without the lower cover. Any automobilist who has ever struggled to line up the bearings of a crankcase which had the two end caps an integral part of the lower half of the case will at once appreciate that this is a big improvement. Not that it was put in there with the idea that the bearings would soon need scraping; far from it, the material used being a hard, die-cast babbitt.

In operation, the motor is exceedingly quiet and free from vibration. The magneto is located on the right-hand side of the motor and is driven by enclosed gearing.



Unit Power Plant Viewed from Magneto and Water Piping Side

Lubrication is of the "constant level splash system." The oil reservoir at the bottom of the crankcase is filled with oil, this oil is forced from this reservoir to the crankcase by a plunger oil pump of large capacity. The amount of oil in the reservoir is observed through a single float oil level gauge.

Water circulating is by thermo-siphon circulating system, all pipes and passages are large to assure a quick and easy passage of water, the inlet and overflow wäter pipes are of polished aluminum. Large water jackets are provided and the radiator is of large capacity. The cooling fan, which is large and well designed, is driven from the crankshaft by a flat belt. From the view of the magneto side of the engine the simple and convenient belt tightener is clearly shown as well as the fan.

Points of Worth in the Transmission Mechanism—The clutch is of the cone type. It is positive, but engages gently. The face of the cone is fitted with renewable leather lining, with springs under the surface of the leather to insure easy engagement. This clutch transmits directly to the main shaft of the transmission. The transmission is the selective type, with three speeds forward and one reverse, gear, shafts run on annular ball bearings. Power is transmitted from here to the rear wheels through two universal joints, a carbon steel propeller shaft, and the usual differential. The rear axle housing is composed of heavy steel castings and tubing, with axle shafts running on Hyatt roller bearings. The two sets of brakes are large and act directly on the rear wheels, one set are external contracting, and one set internal expanding.

Tubular describes the front axle, a tube of large diameter, and of heavy gauge, having the drop-forged yokes riveted and welded to it at the two ends. The cross rod is placed at the rear of the axle out of the way of road obstructions, while the connecting link to the steering gear is above the knuckles. The axle is dropped at the center slightly for look's sake, but the cross connection is left straight, the straight form being better in that it is better able to withstand tension than would be a false shape, such as a long radius curve. Since this member is one which is essential to the safety of the occupants of the car, and since it is always under more or less tension, the idea is an excellent one. In addition to the yoke ends of the axle, the steering knuckles and all connections are drop-forgings. The front axle runs on annular type ball bearings.

Pertinent Facts About Spring Suspension—Comfort is assured by the use of good springs, well selected for length and type of spring, as well as the material entering into their composition. The front springs are semi-elliptic, and rather flat. They are fixed at the front end, while the rear end is shackled. Side sway due to unusual flexibility of the front springs is reduced to a minimum quantity by a cross rod joining the two front spring hangers. This serves a double purpose in that the frame there is stiffened also.

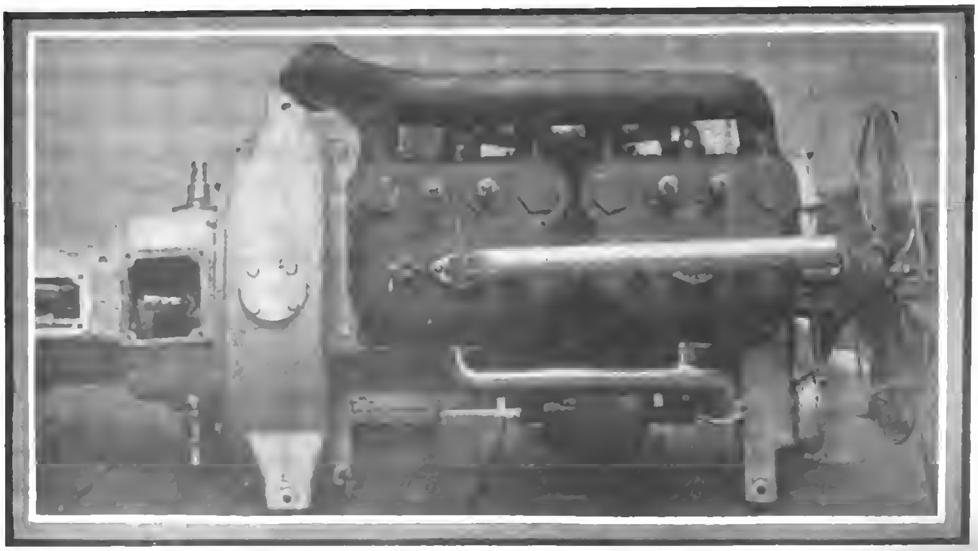
Rear springs are of the full-elliptic type, fixed to the upper side of the axle. All spring eyes are provided with grease cups, which lubricate the moving surfaces, a simple twist with the fingers each day serving to conserve the life of these important members and to eliminate noise.

A pressed steel frame of channel section is used with a sub-frame of the same material, the latter being reinforced, however, by means of a filler strip of ash. The open side of the frame is turned in, while at the front it is narrowed to permit of a much extended turning radius.

The usual tread is used, 104 in. wheelbase, 32 by 3½ in. tires all around, and the weight is given as 2,000 lbs. The tire equipment is worthy of more mention, in that the universal size reduces the extra tires to be carried on a long run to one, since this one will fit any one of the four wheels.

At the A. L. A. M. rating, this motor, which is of 4-in. bore by 4-in. stroke, rates at 25.6 horsepower, but the makers state that every engine sent out from the factory develops actually about 30 horsepower.

At the rating power development, the ratio of power to weight, that is the weight per horsepower is but 78 pounds, which is a comparatively low figure. But, even this is materially lowered when the actual amount of power developed is taken into account. Then the figure becomes 66 pounds, which even with the full rated load of passengers, would not possibly increase to over 75 pounds per horsepower. When this ratio is low, as in this case, high speed, hill-climbing ability, and other useful features are assured.



How the 25-Horsepower Engine and Unit Power Plant Look from Above

IN THE GARAGE REPAIR SHOP

By Thos. J. Fay

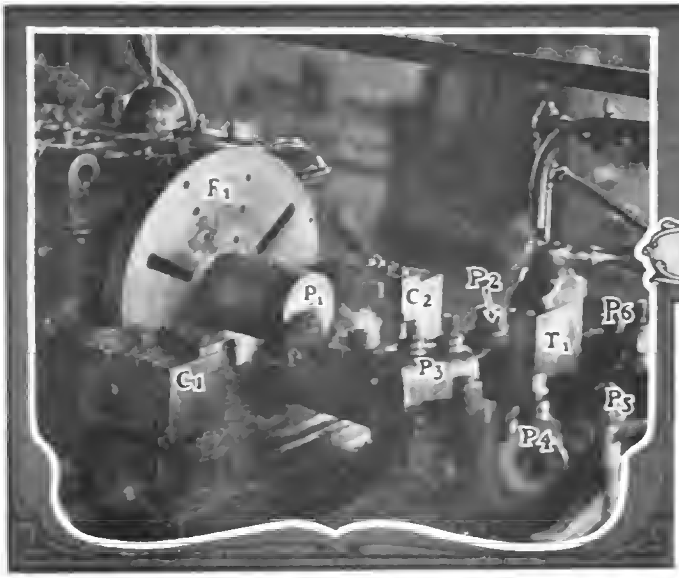


Fig. 1—Turret lathe working on pistons, many different operations being done at once

IT is very likely true that few of the relatively small garage repair shops will be fitted out with a large turret lathe, as shown in Fig. 1 (title illustration). New shops just fitting out might very well consider the excellent advantage of tools of this character, if they are large and substantially constructed.

In garage repair work new pistons have to be made quite frequently, and the figure is an illustration of a piston being finished on a turret lathe, in which F1 is the face plate of the lathe, P1 is the piston, C1 and C2 are side cutting tool holders, and P2, P3, P4, P5, P6, etc., are tool posts on the turret T1. The piston, prior to the present operation, was chucked, utilizing an accommodation piece which was cast on to the head. It was then bored inside to a definite dimension to a point approaching the bosses of the cross-head pin.

The next operation as here illustrated; after the piston was pressed over a mandrel, which is not shown because it is covered up, the work of exterior finishing was started. A turret lathe being capable of doing all the operations from a single setting, results in more accurate work because errors are liable to creep in during the setting up operations. As the work is here presented, the exterior of the piston is turned off, the grooves are completed and the finishing operation of the surface of the head is shown nearly completed.

In the normal course the next operation would be to drill for the cross-head pin, which is also capable of being performed in the same turret tool, which would bring the repair man up to the question of the hardened cross-head pin, which would have to be a press fit in the piston. This question of hardening is of sufficient importance to merit some discussion and will be taken up here, while the opportunity affords, with the hope, perchance, that chameleon methods involving cyanide of potassium will not be inflicted upon the owner of the automobile.

Nearly every workman who has had to do with repair work is imbued with the idea that he has a secret process which, if used, will make the parts everlasting. Against this is the avowed declaration of every metallurgist in the world whose reputation is worth considering, that there is no quick and simple method by which case-hardening can be accomplished with any degree of certainty excepting under conditions as follows:

(A) The material must be of a cementing character.
(B) Time is essential to the success of the process.
(C) The "cement" must be efficient for the purpose.

THE PRINCIPAL CHARACTERISTICS OF CEMENTING STEEL

When steel is cemented (case-hardened) the process has for its purpose the carbonization of the exterior, leaving the core as originally constituted. The reason why it is desired to carbonize the surface is because if the carbon is not in sufficient presence the surface will not be rendered hard in the quenching process. The reason for desiring a soft core is to eliminate the ills which are always present if high carbon obtains throughout the section. Were it not for this latter consideration it would not be necessary to case-harden at all, since the steel might be purchased of a character holding high carbon, and it would be rendered hard by the simple process of heating it to the desired temperature and thereafter quenching it in a suitable quenching bath, of which there are a number of choices as follows:

QUENCHING BATHS IN ORDER OF MERIT

(A) Mercury
(B) Acidulated water, ice cold
(C) Salt water, ice cold
(D) Salt water
(E) Solution of water and skimmed milk
(F) Lime water
(G) Fish oil
(H) Cod liver oil.

These solutions are in order of merit as respects their respective actions on the steel, but not in the order of merit from the point of view of general utility. Mercury for illustration, is

Fig. 2—Workmen dipping cylinder and other castings in pickling vat, previous to machining operations.

a most dangerous metal (in liquid form) to utilize in any heat-treating process, because mercurial fumes are frightfully poisonous and no matter how good the equipment used may be, even if it includes a well-installed exhaust fan, mercurial poison will ultimately affect the operator. For very small parts which are to be intensely hard a bath of mercury properly regulated may be occasionally used with impunity and the degrees of hardness of the quenched small parts will be in keeping with the most exacting needs. When the parts are of considerable mass, thus holding a high value of the heat units to be dissipated, it becomes necessary to utilize a safer quenching bath, and if the steel is of a water-quenching variety it is then possible to resort to the use of water either acidulated or saline.

Ice will go a long way toward maintaining a constant temperature of the water, particularly if the water is agitated during the quenching operation, but taking it as a whole, it is not quite up to the standard which is set in manufacturing plants, where heat-treatment processes have assumed all the proportions of a high art. In these large plants where the quenching operation is conducted with the utmost care, the baths are piped for air under pressure, and a nozzle is placed on the end of the submerged pipe so that when the air valve is opened which permits the air pressure to enter the bath, two ideas are satisfied:

(A) The liquid is refrigerated through the process which produces a lowering of the temperature when a gas (as air) is expanded from a sufficiently high pressure down to the atmospheric pressure.

(B) The exuding air agitates the water or other liquid violently and the vapor globules which form on the surfaces of the parts undergoing treatment are brushed off, due to this agitation, so that the quenching process is completed with the utmost dispatch.

Air to serve as a refrigerant must be expanded from a temperature above 60 pounds per square inch, and it might be advantageous to have this temperature even as high as 100 pounds per square inch. There are very few garages which are not equipped with compressed-air machinery, it being used for the purpose of storing air under pressure in order that it will be available for pumping up tires. This pressure is generally 80 pounds per square inch, and a line leading from this tank to the quenching bath in the repair shop will scarcely have to be with a large diameter pipe, and the results which will be realized will be far beyond the average expectation.

TWO GRADES OF CEMENTING STEEL TO CONSIDER

If the parts to be hardened are to have dual characteristics as highly kinetic and what the German calls "tough hard" the quenching bath will naturally be oil; cotton seed oil is much used in this class of work. Quenching in oil, however, does not produce a glass-hard surface, and if such is desired, cold salt water will be more nearly right. On the other hand, if the steel is not suitable for water-quenching work, the results will be disastrous, particularly if the work includes intricate shapes.

The real difference between the cementing steel which is serviceable for water-quenching and that which might work satisfactorily under conditions of oil-quenching, lies in the purity and the process of fabrication of the steel. In other words, for water-quenching a better product is demanded.

The carbon content will be the same in either case, and it has been stated many times that a cementing steel from the carbon point of view should be so low in carbon that it will not take on perceptible hardness when it is quenched from a high temperature before it is case-hardened. The carbon content to satisfy this condition must be under 20 points, and some metallurgists claim that perceptible hardness will obtain when the carbon content equals 16 points. In some of the best grades of automobile steel, the carbon content to satisfy cementing conditions is limited to 10 points, in which event the steel will serve perfectly, under conditions of water quenching, particularly if it is an acid open-hearth variety, low in sulphur and phosphorus. As a matter of fact, for water-quenching, an acid steel should be used, and the carbon content should be below 16 points.

In garage repair work where it is utterly impossible to consider that the steel will be from special heats, or of a "jewelry" variety, the mistake is sometimes made of selecting fairly good brands of relatively high-carbon steel basic in character, and chemically low in the metalloids. This comes nearer to being a mistake than anything else in the absence of intelligent treatment. It is probably safer to purchase what is known as machinery steel, limiting carbon to less than 10 points, even with the full knowledge of sulphur up to 0.10 and phosphorus keeping it company. The low carbon, to a very considerable extent, masks the metalloids, and after cementation the products work out extremely well for the small parts to which reference is made.

SOME DETAILS IN THE CEMENTING PROCESS

Since in all fairness, it is not possible to grow a depth of carbon by heating the parts to a cherry red, and smearing cyanide of potassium over the surfaces, then re-heating to the previous color and quenching, it becomes desirable to follow some more skillful process, which may be briefly set down as follows:

Pack the parts to be cemented in a cast-iron box, or a length of wrought-iron tubing, utilizing such cement material as ground bone, leather, or other like material, in which a certain amount of the cyanide can be utilized to advantage if the operator will take the pains to definitely compound the material on each occasion, when a batch is being made, in order that he will always be able to judge as to the effectiveness in a given time.

FURNACE USED IN CEMENTING WORK

Fig. 3 shows a cement box C1 on the fire-brick floor F1 over a furnace, as used in the Premier plant, in which the heat is indirect, there being a fire-brick wall protecting the work at all points. The damper R1 regulates the intensity of the heat, and the door S1 is closed. The operator is enabled to observe as to the color due to heat by sliding back the cover of the spy-hole, S1.

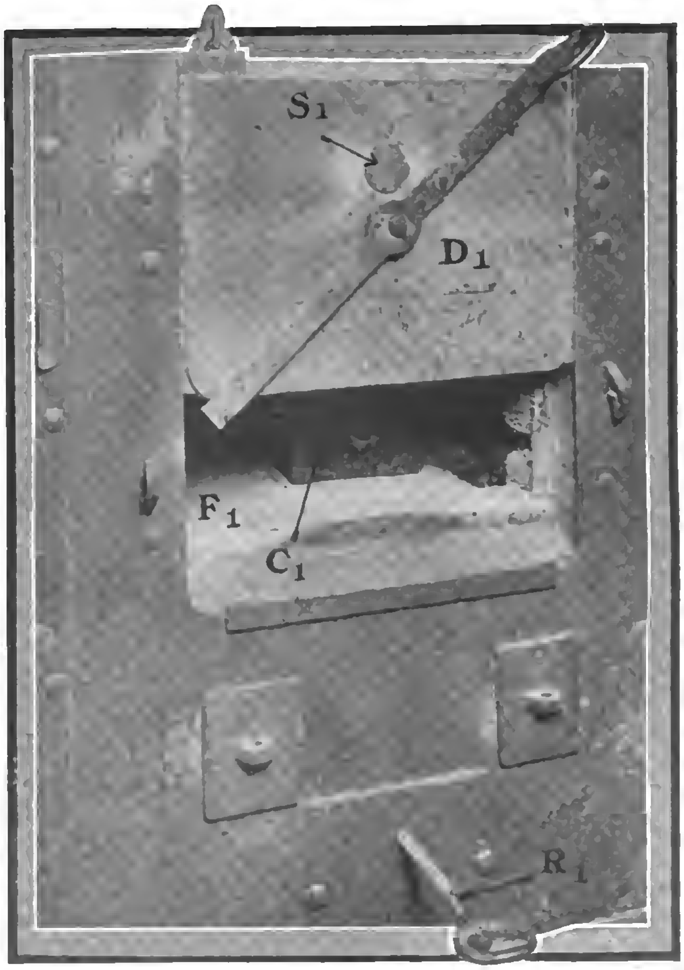

Fig. 3—Furnace in which gears, shafts, and similar parts are heat-treated

ACCIDENTS FOLLOW BLIND DRIVING ON THE ROAD

WINTER is the time when driving is the more difficult due to the presence of slush and snow, the narrowness of the beaten roadway, and lack of tractive ability of the road wheels of the automobile. There are many reasons why Winter driving is only to be indulged in by the autoist who, if accidents are to be avoided, knows how to manage his automobile. In Summer time, when roads are good, it is not unusual to see touring cars of some ability, picking up the road, as the saying goes, with little regard for the distance in which the motion can be arrested, it being true, as will be shown, that it takes a certain distance to stop a car under the most favorable conditions of the roadbed, no matter how good the brakes may be.

This speeding during the Summer's season makes excellent practice towards a first-rate smash-up when snow flies and roads become difficult. The months of practice under favorable conditions make no hint of the hazards which will lie in this same dexterity under the worse conditions to follow. Practice would be advantageous were there any relation between the skill of the driver and the distance in which motion can be arrested, that is to say, the space required in which to stop a given automobile after the brakes are applied.

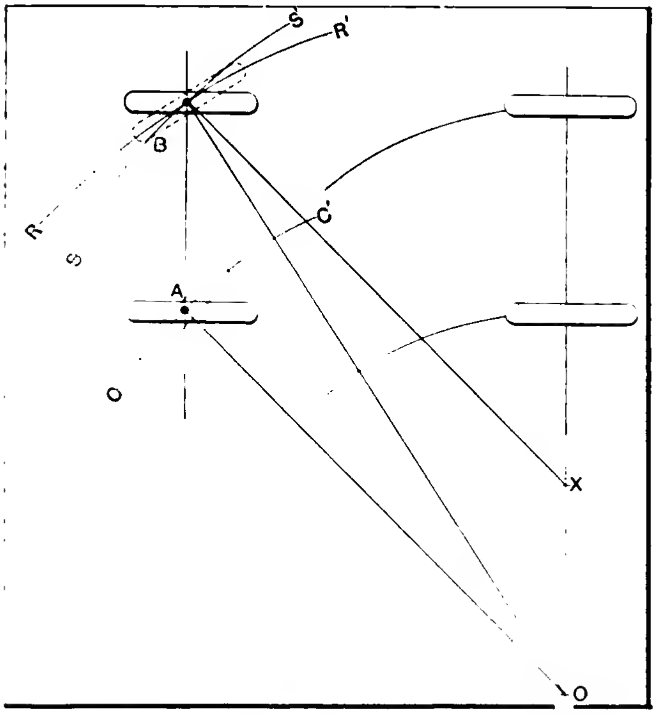

Fig. 1—Illustrating the lack of tracking of the front and rear wheels of an automobile on a curve

STATEMENT OF THE PROBLEM INVOLVING DISTANCE

According to Durand:

Let,

W = weight of the automobile;

F = energy which must be expended in bringing a car to rest, as measured in foot-pounds;

L = distance in feet over which the energy must be expended in the braking effort.

V = velocity in feet per second.

When,

$$\text{Energy} = \frac{W V^2}{2 \times g} = \frac{W V^2}{64.4} = \text{in the abstract.}$$

$$L = \frac{W V^2}{64.4 F}$$

$$F = \frac{W V^2}{64.4 L}$$

Without pursuing this phase of the problem further, granting that the expressions are based on fact, it is possible to make the point in view; the weight of the automobile will be constant,

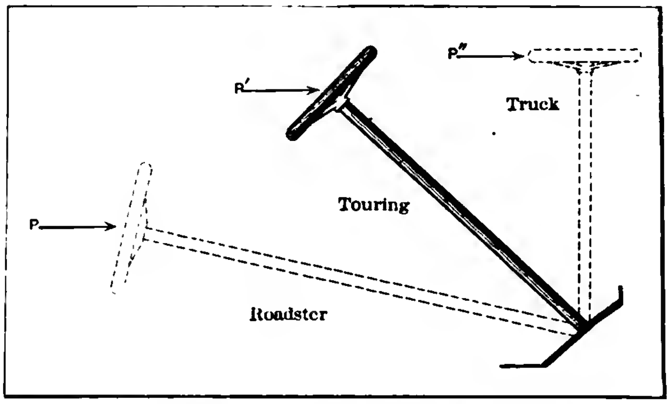

Fig. 2—Indicating different positions of steering wheels, and the increasing tilt with increasing speed

gravity will remain as ever, and the force F, which must be expended, will bring the automobile to rest when the value of the expended force is equal to the energy residing in the moving automobile, and not before.

Thus far there is no limit to the shortening of the time required to bring the car to rest, but it must be remembered that the tractive ability is limited, and, it has been found that traction, if it is exceeded by applying the brakes too hard, causing skidding, eliminates all possibility of stopping the automobile within the shortest possible time.

On a hard, level road it has been found that the tractive coefficient is about 0.60, and, on an iced incline, this coefficient reduces to about 0.10. There are all sorts of intervening possibilities, and it is on this account that autoists who practice up in the Summer time may, without half trying, end up in the Winter's snow-bank, or worse.

According to the accepted coefficient, if each rear wheel of an automobile sustains a weight of, say, 1,000 pounds, then the tractive effort (maximum) must be limited to 600 pounds, for the reason that:

$$0.60 \times 1{,}000 = 600.$$

BRAKES MUST BE IN GOOD WORKING ORDER

To equal 600 pounds on the periphery of a road wheel (at the point of road contact), if the brake-drum is one-third the diameter of the wheel, the pressure on the drum must produce an equivalent of:

$$3 \times 600 = 1{,}800 \text{ pounds.}$$

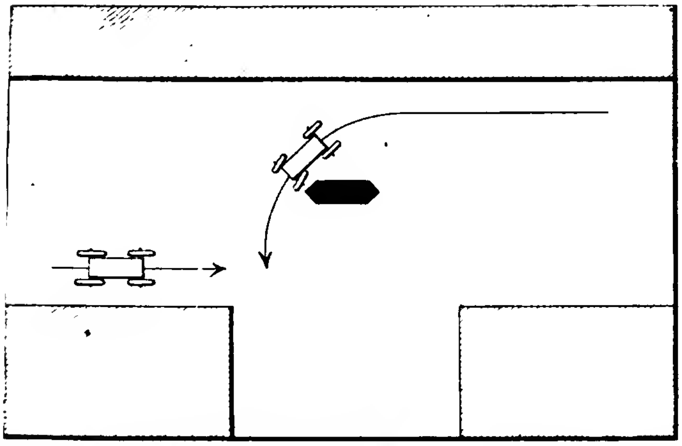

Fig. 3—Showing an approaching and a turning automobile under conditions of great danger

This drag on a brake drum of 12 inches in diameter would be:

$$P = \frac{1{,}800}{f} = \text{pressure applied by brakes.}$$

When

f = coefficient of friction of the brake shoes.

The coefficient depends upon the nature of the material used for facings on the shoes, and may be:

0.33 for cork inserts; 0.25 for asbestos fabric; 0.16 for dry leather; 0.08 for metal to metal.

Granting that the facings are so efficient as to afford 0.25 as the coefficient, the actual pressure will have to be:

$$P = \frac{1{,}800}{0.25} = 7{,}200 \text{ pounds.}$$

REAL DANGER LIES IN TURNING AT HIGH SPEED

Thus far it has been the aim to indicate briefly the possibilities, and it will now be in order to point out that all these limitations fail if the direction is not in a straight line. Just what it means to make turns at high speed is a matter to be treated at some

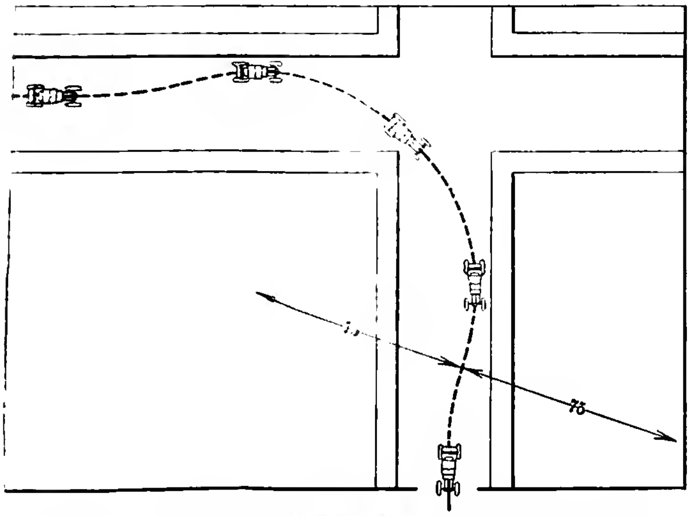

Fig. 4—How automobiles whisk around corners in high disregard of life, limb, and property

length, and, for the better understanding of the dangers, it will be taken up as a separate matter.

In driving, then, make speed on a hard, level road, when the line of vision is not intercepted by foliage, buildings, turns, etc. When it is necessary to turn out, slow down; if crossings are ahead, slow down anyway. Fig. 1 is offered to indicate that front and rear wheels do not "track" and that skidding is likely, even entirely beside the law of centrifugal force, because the rear wheels are very likely to find a bad spot in the road, even if the driver does guide the steering wheels in a good part of the road.

Fig. 2 is offered to illustrate another phase of the problem: If the location of the steering wheel is different from that which obtains in some car to which one may have become accustomed, it is dangerous to jump into the car and "hit it up" before becoming practiced and getting used to the new location. Standardization is one of the crying needs on this very account, and it is much to be hoped that the time will arrive when all automobiles will be exactly alike as to the steering gear and control.

Fig. 3 offers an opportunity to discuss the question of right away, and, with the "island," as shown in the middle of the road, it is easy enough to see that the automobile which is making the turn is in the right position, but this is no indication of the fact that this car should come to rest to enable the approaching car to go by. The driver of an approaching automobile would be justified in the belief that the turning car is going straight ahead, and it is the duty of the driver to see that the way is clear.

Fig. 4 illustrates the way turns are made when the guardians of the peace are out of sight, and, while there is no denying the

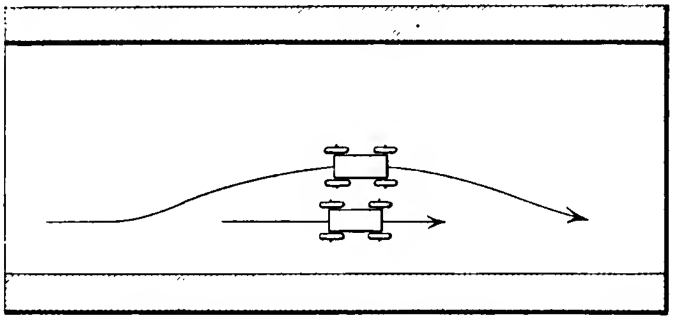

Fig. 5—Proper method of passing an overtaken vehicle, turning out to the left, which is then correct.

contention that it is the right way to do a curve at the highest possible speed without skidding, it is, nevertheless, wrong; the end will be an accident. This may be stated with certainty.

Fig. 6 shows how a turn should be made, but it must be remembered that a lookout must be kept for approaching automobiles, on the ground that the automobile which is about to make the turn has no right before the turn is actually made in safety to the car, other automobiles, and the public at large.

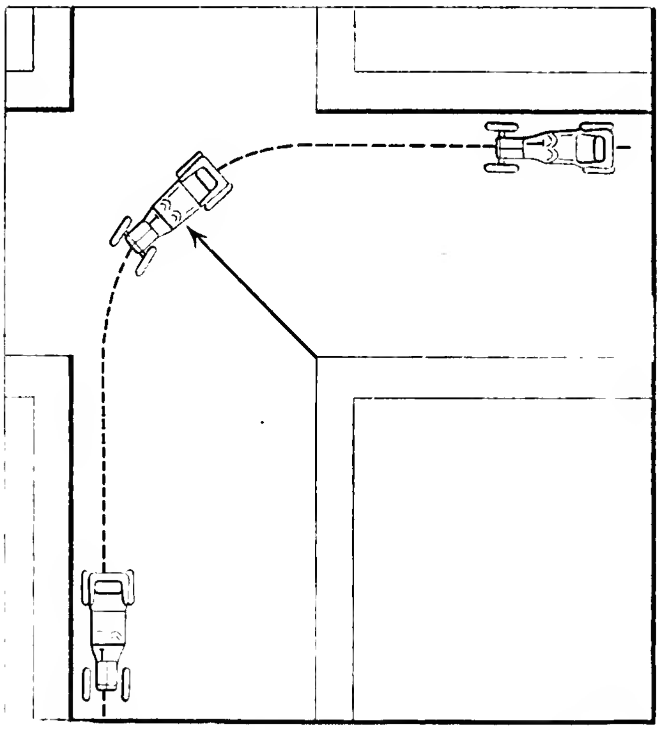

Fig. 6—How automobiles go around corners on a safe basis if the driver remembers his responsibility

GAS VELOCITY FORMULA

Editor THE AUTOMOBILE:

[2,149].—Will you please publish a formula under "Letters Interesting" for the velocity flow of gas through a 2 1-4 in. valve on a four-cylinder, four-cycle automobile engine of 4 1-2 in. bore by 5 in. stroke, 1,250 ft. piston travel, 78 pounds compression?

Racine, Wis. J. F. SLADKY.

The velocity flow depends upon the sizes of the pipes, as smaller pipes require a faster flow to supply the same amount of gas, while larger pipes would permit of a slower rate of flow. The size is usually formulated from the speed of gas flow. For exhaust gases 10,000 ft. per minute, and for inlet gas speed 6,000 ft. per minute are usual practice.

For the cylinders mentioned, the capacity is 79.52 cu. in. per cylinder every two revolutions. With the given piston speed and length of stroke, the rotary speed is 1,500 r. p. m. So the motor demands are

$$\frac{1,500}{2} \times 79.52, \text{ or } 59,610 \text{ cu. in. per min.}$$

This is equivalent to 34.5 cu. ft. per minute. Since the gas speed is known and the motor demands, also, dividing one by the other gives the area of the pipe which will allow that amount of gas to pass at that speed. Thus:

$$\frac{35.5}{6,000} = .00591 \text{ cu ft.} = 10.21 \text{ cu. in.}$$

Now, as the pipes are round, this area may be looked up in any table of area of circles, from which it is found that the diameter would be 3 5-8 in. Increasing the gas speed to 8,000 ft. decreases the diameter to 3 in., while a still further increase in speed to 10,000 ft. results in a pipe size of 2 1-2 in.

Put into formula form, this becomes:

$$\frac{ARL}{6,000 \times 12 \times 2} = \text{size of pipe.}$$

In which A is the area of the piston in square inches, L the stroke in inches, R the revolutions per minute, and the denominator is the allowable speed in feet per minute reduced to inches, while the factor 2 reduces the revolutions to one-half, on account of the gas being drawn in or exhausted but every other revolution. If the results do not suit, alter the first figure of the denominator to suit.

FIRING ORDER 8-CYLINDERS

Editor THE AUTOMOBILE:

[2,150].—Referring to the enclosed sheet, upon which I have given a number of firing orders, are these correct, and are there any more ways to fire an eight-cylinder, four-cycle, vertical engine with four-throw crankshaft, two cylinders to each throw, cranks set in pairs 180 deg. apart, pair groups 90 deg. apart? To make it clearer, I will say that the first and second cylinders are on one throw, third and fourth on another, each pair being 180 deg. apart; fifth and sixth and seventh and eighth are arranged in the same way 180 deg. apart, but the last two pairs are 90 deg. apart from the first two. Cylinders to fire 90 deg. apart. These are all of the different ways I could think of, and if there are any more I would like to have them. Please answer through "Letters Interesting, Answered and Discussed." A SUBSCRIBER.

On the enclosed sheet spoken of above are given all of the possible combinations of the eight numbers, 128 in all, some of them, in fact, being just the inversion of those previously given; that is, a number are given twice, the second being but an inversion of the first. The table is not reproduced for lack of space. Eliminating these, and also those in which the order as a whole is the same, but simply starts with a different number, the number of firing orders will be less—much less.

If the first and second cylinders are in the same pair, that is, in the same casting, while the third and fourth are also side by side and in the same casting, there must be an interval of 270 deg. after each 90-deg. interval. If, on the other hand, the first cylinder is in the same casting with number three, and number two with four, one and two being upon the same crankpin as described, while three and four are upon the next pin together, then, and then only, will it be possible to fire the cylinders so that there will be an exact and constantly recurring 90-deg. interval.

On page 117 of his work on "Balancing of Engines," Archibald Sharp discusses this subject in a very thorough manner.

COST OF COMFORT

Editor THE AUTOMOBILE:

[2,151].—Please give me some information as to tires without air—that is, solid tires, which have some sort of an interior air compartment, but which are not pumped up by means of air. READER.

Coldwater, O.

In the use of a tire of this sort, the majority of people taking them up are not only willing but glad to exchange the freedom from puncture for almost anything. With proper springing and semi-solid tires having a central, non-pumped-up air cushion, the riding qualities are all that can be desired, while the construction is such as to allow the driver to absolutely forget that such a thing as a puncture, air leak, etc., actually exists.

MAKERS OF AXLES

Editor THE AUTOMOBILE:

[2,152].—Will you please give me a little information? I have a rear axle, of which I would like the maker's name. The only mark on it is "H-D" or "O-D"; the stamp is not very plain, so I can not tell exactly which. The gear box is spherical in form.

Reading, Mich. C. A. BROWN.

We are unable to give you the name of the makers of this axle, as the mark (either of them) is one we have never heard of. The makers of this axle are invited to send in the name of their company, or, if preferred, may communicate direct with this party. Any one recognizing the make of axle is invited to help this party out of the dilemma.

FOND OF NICE BODIES

Editor THE AUTOMOBILE:

[2,153].—I beg to differ from you on the question of the automobile body as discussed in an editorial in The Automobile some time in December. The automobile is so unlike a carriage; you can have a magnificently finished carriage body and keep it fine; because of the large wheels and narrow tires it does not get all splashed up with mud and become spotted. It can be kept showy and for display. Not so with the automobile body; its speed, its small wheels with broad tires, which splash mud all over the body, likewise dust. It is more like a battleship in action, and hence the body should naturally, logically, and common-sense-like differ from the luxurious carriage body. The torpedo body refined is the body, and should be the new aluminum metal painted battleship, gray and not varnished. Nor should it be luxuriously rubbed down and recoated 18 or more times, just like a piece of parlor furniture. It soon gets all spotted up, and looks no better than a good job of painting. Then, if it were so made, it can be easily washed and wiped off, and, if marred, touched up and kept looking nice, yet have the look of utility, comfort and commonsense to it. The manufacturer who educates his clients to good practice along these lines, that the automobile is to use and not display, will win out by and by. W. P. LUCAS.

Oil City, Pa.

Little comment on the above seems necessary, except to say that instead of being a thing of the future, the body described is very much a thing of to-day, both of the Shows, just closed, showing a number of this kind. However, there will always be a very large class of people demanding and willing to pay for the highly finished body. This, too, in spite of the facts, so well brought out above, that the more highly finished the body, the greater the amount of work connected with keeping it in a condition commensurate with its finish.

ON HORSEPOWER RATINGS

Editor THE AUTOMOBILE:

[2,154].—Have you a chart or table for distribution showing rated horsepower of cylinders of various sizes? If you have not such a table, but the information has been given in your magazine, will you mention the date of issue? W. G. DUFFIELD.

Ottumwa, Ia.

The great majority of makers in this country use the A. L. A. M. formula, which is the bore of the cylinder squared times the number of cylinders, divided by two and a half. That is:

$$\text{Power} = \frac{2.5}{D^2 \times No.}$$

From this any sized engine will readily be computed, or by referring to the issue of The Automobile for January 14, 1909. page 100, you will find all of the common sizes, both in inches and millimeters, computed and listed in tabular form. In addition, you may obtain the same information from the handbook of the A. L. A. M., which is distributed gratuitously from the office at 7 West Forty-second street, New York City.

DIRECT FUEL INJECTION

Editor THE AUTOMOBILE:

[2,155].—Will you kindly answer the following questions through your column, "Letters Interesting, Answered and Discussed"? 1. I am designing a motor in which the fuel is to he injected hy means of a pump. The area of my cylinder is approximately 37.77 cu. in. and the clearance space 11.25 cu. in., giving a total area of 49.02 cu. in. What should he the diameter and stroke of my injecting plunger and the size and shape of the nozzle through which delivery is made into the cylinder? The design is such that at the time of fuel injection there can he nothing present in either cylinder or compression space save pure air.

2. In order to ohtain crankcase compression of 7 pounds per sq. in., what should he the crankcase volume as compared to the comhined volume of cylinder and compression space?

3. Assuming free air at 60 deg., what will be the temperature if compressed to 7 pounds pressure; also, what will he the drop in temperature due to instantaneous expansion of a given volume of air at this pressure, provided no moisture is present?

4. Is there any ohjection to the use of a steel casting for a motor cylinder where air cooling is contemplated, and, if not, what general reduction could he made in thickness of cylinder walls, as compared to cast iron?

5. If using inserted valve seats, what material would you recommend as capahle of standing up heat under high temperatures, also what would he the hest material for valves? LINCOLN A. LANG.

Castile, Wyo. Co., N. Y.

1. If the pump is so geared up as to deliver to each one of the cylinders in rotation, so that the size of the pump will be such as to equal the capacity of one cylinder per stroke, the bore and stroke should be so determined as to yield a weight of gasoline equal when vaporized to one-fifteenth of the total volume which you have given as 49.02 cu. in. That is, considering 15 to 1 as the proportion of air by weight, the pump should deliver its one-fifteenth. Delivery to the cylinders would best be made through an expanded nozzle to spread the spray around.

2. Compression follows approximately the law expressed as a formula in the form

$$\left(\frac{V_1}{V_2}\right)^{1.[illegible]} = \frac{P_2}{P_1}$$

in which V_1 is the original volume, P_1 the original pressure, V_2 the final volume, and P_2 the final pressure.

Taking 14 pounds per square inch as the original pressure and 14.7 pounds $+ 7 = 21.7$ as the final pressure, the volume is easily obtained by substitution, as:

$$\left(\frac{21.7}{14}\right)^{1.[illegible]} = \frac{49.01}{P_1}$$

Working this through, the answer is 88.8 cu. in. volume of crankcase to give 7 lbs. pressure, gage.

3. By substituting for V_1 T_2, and for V_2 T_1 in the above equation, the temperatures may be figured. The instantaneous drop cannot be figured in any simple manner.

4. Steel has been used for cylinder castings, and more particularly, for pistons. The principal objections to its use, if there can be said to be any, is the difficulty of casting it sufficiently thin for such parts as water jackets. If the cylinder in question was intended to have overhead valves and be air-cooled, there should be no trouble. The reduction in size or thickness should be made in the ratio of the strengths of the two metals. In this connection, Unwin gives cast iron an average tensile strength of 17,500 lbs. and cast steel 63,000 lbs. These figures would give a ratio of 1 to 3.6, or, say, 1 to 3. On this assumption it would be possible to make the steel cylinder walls one-third of the thickness which would be used for cast iron. However, do not take these figures as correct, and do not go below one-half of the usual thickness for iron.

5. Cast iron is considered very satisfactory for valve seats, while carbon-steel stems welded to a nickel-steel head makes an excellent valve.

CRYSTALLIZATION DANGER

Editor THE AUTOMOBILE:

[2,156].—At some cost of space, kindly permit me to recite a condition which confronts many autohomilists and for which they know of no remedy, hut which you may. I am still driving a 1907 car. It is a good one, stands up well, and answers my needs in every way. I am therefore reluctant to part with it, hecause of its present excellent service and for the further reason that the purchaser would he exposed to a hazard which I now feel is far from inconsiderahle. I refer to crystallization. The car has gone all of 10,000 miles, possibly 15,000, and I never get in it without the applehension that the axles or steering knuckles or rods or some part of the chassis may he crystallized through vihration and he no more than so much punk. It may go to pieces and run me and mine into ohlivion "without henefit of clergy" or other alleviatory circumstances. What thousands of owners wish to know is some method of detecting crystallization. There ought to he some process. Will you enlighten up, and thus enable many to add a needed sense of security to the joys of motoring?

HERVEY C. LIPPINCOTT.

Philadelphia.

Danger from this source is much exaggerated. If this were not so, would anyone be safe in riding in railroad trains, trolley cars, or other vehicles of a similar nature, in which a metal axle is used?

As for detecting such a remote possibility as partly crystallized axle or other piece of metal, there is no instrument known which will do this.

The crystallization of metals under repeated stress is an action which is not fully understood even to-day, some chemical engineers claiming that the allotropic changes in the constituents of the steel work out in a larger percentage of the softer alloys, in which manner the metal, as a whole, is weakened.

CORRECT PISTON CLEARANCE

Editor THE AUTOMOBILE:

[2,157].—Will you answer the following question? I have my car down and want to get it ready for another season. It has a high speed engine and not very much compression. My new set of piston rings help some in that line, hut the wear soon tells. The pistons are about nine one-thousandths (.009") small, the diameter of the cylinder 3 3-4 in. If I put in new pistons and allow ahout four one-thousandths (.004") clearance, will I get any bad effect, or will I have what the engine needs and should have had long ago? E. R. DAVIS.

Rockland, Me.

While the figures given differ from current practice, if the proper rings were used, the size of the piston should have no bearing upon the speed or compression. Usual practice in this respect is three-one-thousandths (.003) at the bottom and five-one-thousandths (.005) at the top, where the heat is greater, and consequently the expansion also. It is upon the rings that you depend for gas-tightness, and if you are not getting it, get new and stiffer rings. The change suggested might be tried, but stiffer rings would be better.

LEFT-HAND DRIVING

Editor THE AUTOMOBILE:

[2,158].—Will you state through "Letters" the so-called advantages of having the steering wheel and driver located on the left hand side of the car. C. M. LINGLE.

Graceton, Ind. Co., Pa.

Chief among the many advantages of left-hand driving is the fact that the driver is closest to all vehicles which he meets, and can thus avoid them most easily. Another reason is that a front seat passenger may be discharged at the curb without crawling over the driver or steering wheel. The weight of the driver balances the torque of the motor, and also, the inclination of the car due to the camber of the road.

GEAR-GRINDING NOISES

Editor THE AUTOMOBILE:

[2,159].—I have a Chalmers-Detroit type F car, made in 1909, which has always had the disagreeahle grating rattle at critical speeds, the same as your correspondent of the Decemher 9, 1909, issue. The manufacturers advance the theory that this is due to a vihration of the gears in the change speed transmission, and have agreed to replace these gears with others of a much tighter fit. Do you consider this change as one that would decrease the noise.

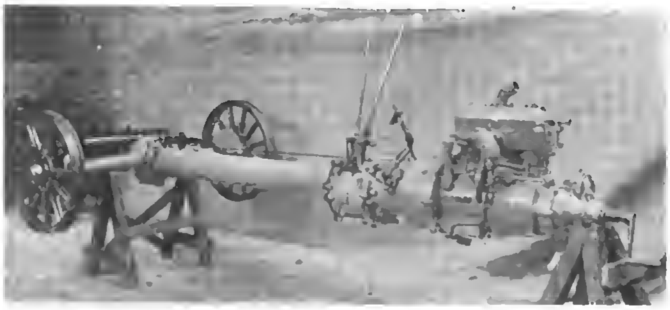
W. IRVING KIMBALL.

Philadelphia.

This change would very likely eliminate the noise entirely, else the makers would not have suggested it to you, since it is to their interest to have the car run as quietly as is possible. More than this they would hardly furnish you a new set of gears and a shaft free of charge, unless they were sure that it would help out in your present dilemma. In a letter from this firm, relating to the other correspondent to whom reference is made, the idea is advanced that much noise comes from an improper adjustment of the driving bevel gears in the rear axle. This is a matter which requires considerable experience in order to be sure that the gears are really meshing on their pitch lines.

A NEW FRENCH LIGHT CAR WITHOUT A CHASSIS

CARRYING along the tendency toward unit construction, of late an increased number of automobiles have been noted on which the whole effective mechanism is grouped in two parts. This construction takes two forms; in one the engine, clutch and transmission form the front unit, while the rear axle constitutes the rear or second unit. In the other, the engine and clutch form



Simplicia Chassis-Less Car as It Appears from Front

the front unit, while the gear box is an integral part of the rear axle a la Packard, this forming the second or rear unit.

In a recent French invention this process of combination and simplification is carried one step further, in that the engine, clutch, transmission, rear axle, torque tube and all operating levers are united into a single piece or unit. To the forward end of this the front cross-spring may be pivotally attached, the whole then constituting an automobile minus a body. This constitutes, then, the frameless car, or, as the French call it, the car *sans chassis.*

While the car has many advantages and disadvantages as compared with the ordinary car built up with a frame, it will be advisable to look into the construction first. With this idea in view, two pictures of the complete unit, as well as a constructional drawing, are herewith presented.

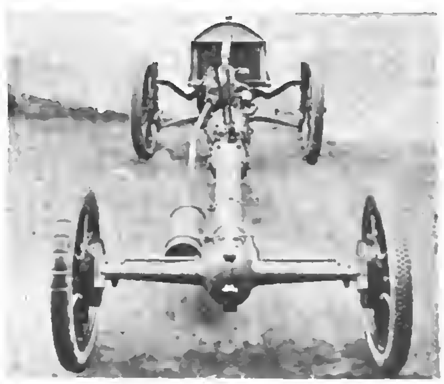
The engine is of the four-cylinder type, cast *en bloc*, the sizes being 75 mm. (2.95, almost 3 in.) bore by 100 mm. stroke, the English equivalent of the latter being 3 15-16 in. Roughly, then, the engine is 3 by 4, which would give a power rating of 14 horsepower. The makers, l'Aster, however, rate the engine unit at but 10-12 horsepower.

To the rear end of the crankcase, which is of the barrel type, with circular plates closing the ends and forming the end bearings, the clutch casing is bolted up, much on the style of the Chalmers-Detroit 30. The flywheel is of small diameter, as the design would seem to require, but this deficiency is made up by its length. At the rear end of the flywheel is carried the double cone clutch, close-coupled to the gear box, which furnishes three speeds and reverse, operating selectively.

To coact with the gear changing and facilitate the same, a shaft brake is furnished, which consists of an expanding band working in oil. To the rear end of the transmission case is fixed the torque tube, which in this case also acts as the connecting frame of the front and rear parts. This tube is apparently about 6 in. in diameter, with metal walls of a thickness between 5-16 and 3-8 in. It terminates at the rear end in a housing for the bevel gears and usual rear axle construction. The rear axle is of the full floating type, with the axles driving the wheels at the outer ends through the medium of jaw clutches.

Barring the engine, all rotating parts are mounted upon ball bearings. Motor cooling is by thermo-siphon, and the lubrication is force feed, with a gear-driven oil pump. In addition to the shaft spinning brake previously mentioned, a set of internal-expanding rear-wheel brakes are provided, these being operated through rods and levers mounted upon and carried by the large diameter main tube.

In the construction shown the tread is 53 1-2 in., and the wheelbase 98 3-4 in., but for larger car bodies—this one is for a taxicab—the tread may be increased as well as the wheelbase. Of course, with a longer wheelbase, as 101 1-4 in. for a double phaeton body, the tube becomes longer, all of the other parts remaining the same. Neither the construction nor the literature sent out by the makers, Lacoste & Battman, 15 Rue Danton, Levallois-Perret (Seine), France, show any change of diameter or thickness of metal for this elongation.

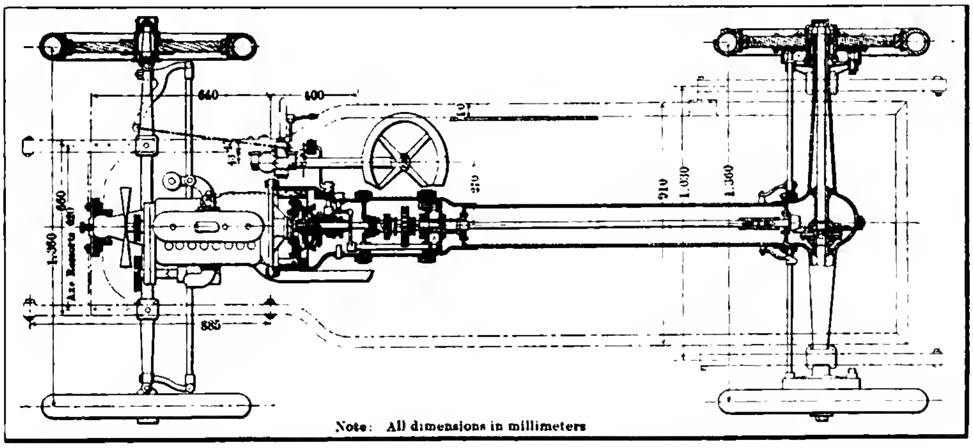


Simplicia Construction from Rear

Complete as shown, but without the front axle or steering gear, which appears to go with the axle as another unit, the weight is 400 kg., while the outfit with these items added, as well as the very necessary radiator, but without tires, weighs 550 kg. The former is equivalent to 882 pounds and the latter to 1,213 pounds. In the former condition the selling price is 4,400 fr., or $880, and for the latter 5,200 fr., or $1,040.

It might be pointed out that while this appears at first glance as simplicity simplified, when all things are considered, it is not. Thus, no provision is made for springs, radiator and water connections, lubricator telltale, ignition connection, steering gear, spark and throttle levers, gasoline tank and connections, etc. These would have to be added in part to the unit shown, while others would have to be carried by the body. Similarly, the whole rear weight appears to be unsprung, which, to put it mildly, would be hard on the wearing qualities of the parts.

More than this, the tube forming the main strength of the combination appears very light. Not every one likes the operating levers at the left, as this design locates them, with the driver at the right-hand side.



Working Drawing of Simplicia Construction, Showing Clutch, Transmission and Main Tube

NEW PEERLESS FRICTION SHOCK ABSORBER

IMPORTANT describes the position which is occupied by shock absorbers on automobiles. This was never better understood than it is at the present time, it now being realized that the life of the working components of an automobile is absolutely dependent upon:

(a) The dynamic characteristics of the material used.

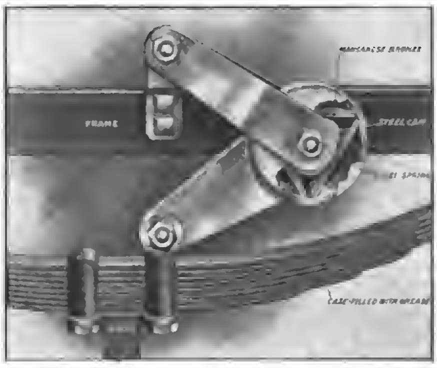
(b) The dampening of shock.

It makes no difference how good the material may be, its dynamic life is limited nevertheless, the only difference being that life will be longer if the material is better in a kinetic sense. Insurance statistics seem to prove more or less consistently that the life of a car increases enormously with its ability to travel fast, and high quality of material and construction does not apparently add sufficient to the life to satisfy the extra expenditure made to produce this quality.

It will be a matter of years, perhaps, before the law of the automobile as a road performer will be sufficiently understood to enable engineers to determine with absolute certainty as to the best way to definitely prolong life. As it is, even though engineers are working in the dark, to some extent, the fact remains that any method by which easy riding qualities may be induced into automobiles is the very one that is at the bottom of shock defeating conditions. Designers seem to be well along on the right road.

The extent to which all these conditions obtain depends upon the spring suspension of the automobile in so far as springs are capable and upon shock absorbers for the rest. The shock absorber situation has taken on an extremely important bearing in view of results obtained, but the accessories of this character, when they first put in an appearance, were scarcely equal to the character of the work which they were required to do. Improvement has been rapid, consistent, and it is now fairly understood that the shock absorber situation mechanically is on a sufficiently high plane to debar it from discussion in the haunts of incapacity.

The new Peerless shock absorber as here illustrated is so clearly presented that discussion would scarcely seem to add value unless to point out that the steel cam works against flat springs, placed in a triangular relation within the housing, and since the cam contour may be fashioned for any desired relation of resistance to action, it is possible to realize the most agreeable riding qualities, dampen the vertical bounce in the proportion which will eliminate shock, and adjustment of any kind becomes practically unnecessary, since all the faces are glass-hard and stability is the prime characteristic. This shock absorber is manufactured by the J. H. Sager Company, Rochester, N. Y.



New Peerless Shock Absorber

BALL AND SOCKET JOINTS WIDELY ADAPTED

THIS year there is a considerable migration in the direction of some of the earlier practices as they obtained in electric vehicle building a few years ago. Old-timers will remember that ball and socket joints were much used in some of the earlier vehicles, and it now seems that the fine qualities residing in this class of work are being missed. The illustration here offered is of the latest Pierce-Arrow practice, and, if cars of this make are examined, it will be found that there is a considerable addition of this type of joint, taking the place of "yoke" joints in several places. Last year the ball joint was limited to steering drag and cross rods, but now it is not uncommon to find that the ball joint is substituted. What is true of the cars already named is equally to be observed in Peerless, Packard and numerous of the other makes as well.

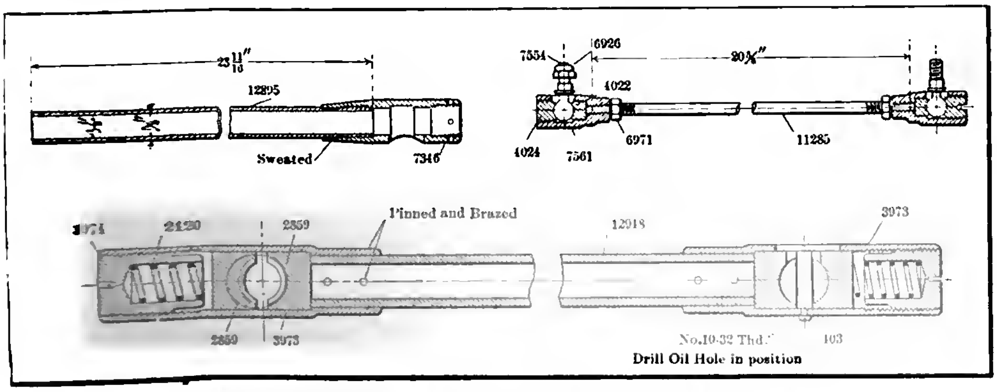
It is not always necessary to have the universal principle present in these links and levers, and in some of the cars this year a mixed system is employed. The ball and socket joint in these cases is limited to the members which have to be universal, and the yoke idea obtains for the balance. Fortunately when the universal joints are of good design the work imposed upon the remaining joints is very much reduced, and the final result is by way of a substantial improvement. That this reversion to an old idea is along permanent lines is more nearly true now that the methods of manufacturing ball and socket joints are so much refined as to eliminate the main reason for having abandoned them, some two or three years ago on the score of first cost, they are now cheaply made.

The advantages derived from the use of ball and socket joints are too well understood to require explaining, but the fact is sometimes lost sight of that a spherical bearing presents considerably more surface than that which will be available with a bolted yoke system. As an illustration of this point it is only necessary to make a single comparison:

(a) Pin bearing 1-2 x 1-2 inch affords 0.25 square inch of projected area provided the fit is within close limits of tolerance, which is not always true.

(b) Spherical bearing 1-2 inch in diameter, gives 0.7850 square inch, one-half of which would be 0.3925 square inch.

The advantage of adjustment is much in favor of spherical bearings in work of this character, and this is worth more, perhaps, than any other one point. The parts illustrated show evidences of much refinement, and it now looks as if the small parts around the carbureter and ignition systems of automobile motors will have parts of this character in the future to a considerable extent, they being preferred on account of quality.



Details of Component Parts of Pierce-Arrow Ball and Socket Joint

CONTROL SYSTEMS INVOLVING THE CARBURETER

DRIVERS, especially in trucking and delivery service, due to the high gear ratio of the "direct on high gear" system, usually the bevel drive, find it a little difficult to manipulate the control system in such a way as not to damage the motor when the desire is to slow down or stop. De-clutching is the first operation, but if, in performing this operation, the spark is not retarded, and the mixture throttled, the motor will "race."

The extent to which a motor will speed up (race) when the load is suddenly relieved as in de-clutching, depends upon the characteristic of the motor. To induce this undesirable racing, a motor should be designed as follows:

(a) The compression should be maximum possible within allowable limits from the point of view of pre-ignition.

(b) Valves should be as large as possible; half the bore of the cylinder being a good figure.

(c) Timing of the valves should be excellent; over-lapping and nice relations of inlet and exhaust valves with respect to the travel of the pistons would add.

(d) The valve motion should be as free from inertia as possible, in order to realize prompt closing.

(e) Springs, placed to close valves, should be of the right strength and alive.

(f) The carbureter should be with a sufficiently large opening, and wide enough in its range of good mixture to respond to sudden speed changes.

(g) The intake manifold should be relatively large in area; the suction depression should be limited.

(h) Exhaust manifold openings should be of large area, straight, and well balanced from the gas transfer point of view.

(i) Back pressure, due to inferior mufflers, should be avoided.

(j) Ignition should be thoroughly capable from the energy point of view, and well timed.

When all of the above conditions are properly cared for, the motor will accelerate at a terrific rate if load is suddenly relieved.

PUMPING LOSSES SHOULD NOT BE TAKEN ADVANTAGE OF

In an internal combustion motor of the types used in automobile work, the pumping losses, so called, are largely due to the very fact that the motor must pump the mixture into the cylinders, and pump the exhaust products out at the proper time, hence pumping losses. There are no pumping losses in a steam engine because the steam is generated under pressure and flows in inaided by suction of the engine; the exhaust flows out under pressure, and "clearance" is reduced to a minimum. In automobile motors the clearance is relatively very great—20 to 30 per cent.

If, in attempting to solve the control problem, pumping losses are taken advantage of, it is obvious that the ability of the power plant will be diminished accordingly, and it will then be right to state that, to prevent a motor from racing when the load is removed, it is necessary to fine it, so to speak, during all the time when it is doing its duty.

DISCUSSION OF THIS PROBLEM IS WHAT IS WANTED

If, in the near future, this matter could be "aired," it is more than likely that the accumulation of information which is bound to come from intelligent discussion, will result in much good to the industry. There are a great variety of conditions to be considered in a discussion of this sort, and, in all probability, some of the discussion would have to be revamped for special applications.

Fig. 1 shows how one truck builder went at it, preferring to employ a governor to control the speed of the motor when the clutch is removed, to obviate fusing the motor during its normal working periods, rather than have it run inefficiently on the one hand, or depreciate very rapidly, as it would, were no provision made to prevent excessive speeding. Inertia increases enormously with speed, as was shown in a discussion in THE AUTOMOBILE of December 23, page 1,096—Fig. 13.

The governor, Fig. 1, in this article, is of the horizontal flyball type, with a spring reaction, and it is connected to the auxiliary air valve of the Schebler carbureter in such a way that, when the motor is relieved of its load the governor throttles the mixture—at all other times the mixture is adjusted by the action of the governor for best results.

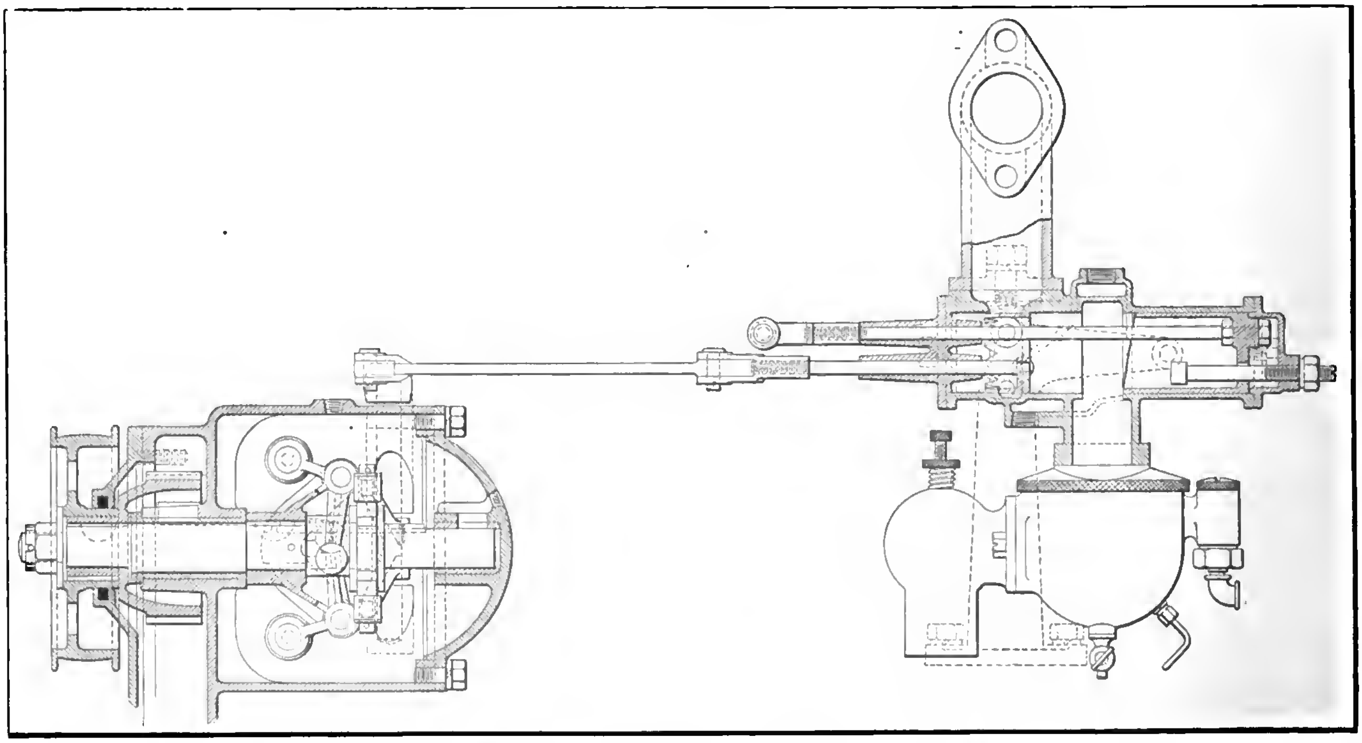


Fig. 1—Automatic control of carbureter, by means of a governor, as used on power plant of Alden-Sampson trucks

Homogeneousness of Mixtures Advantageous

Fig. 1—Ball bearing mounting of the shaft of Homo gasoline economizing device

AMONG the particularly interesting devices which came to public notice during the show period in New York this year, the Homo attracted a great deal of favorable comment, and in view of the importance which it occupies in the power plant part of automobiles, its priciples should be discussed.

This device is placed between the carbureter and the intake side of the motor, preferably close to the carbureter in the system, and it has for its purpose the function of splitting up the globule characteristics of the stream of gasoline which is entrained in the inrushing column of atmospheric air. The reason for desiring to destroy the globule formation of the atomized gasoline will be found if account is taken of several conditions, as follows:

(A) Liquid gasoline must be reduced to gas form, hence changed in its state of aggregation, requiring the exchange of heat in sufficient presence, before a mixture of an explosive character can be formed in the combustion chamber of the motor.

(B) The ability of the liquid in its atomized state to take up heat in a given time depends upon the surfaces of the sphere-like globules which form the atomized spray. The law of the surface of spheres must here be taken into account, in which the surface for mass is not in proportion.

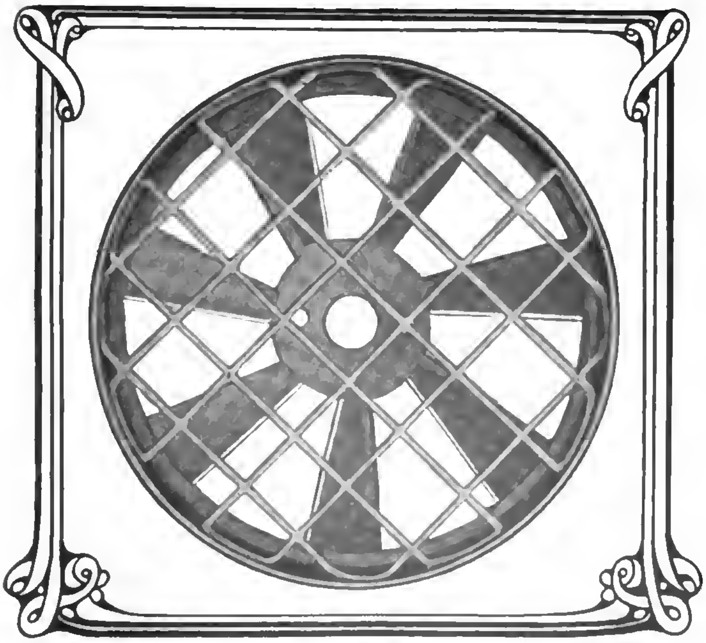

Fig. 2—Fan, which forms principal part of Homo device, and netting covering same

(C) Liquid gasoline if it is permitted to enter the combustion chamber of the motor will be broken down so rapidly after ignition that carbon will coke out.

(D) The exchange of heat which is necessary to form a gas out of a liquid depends upon the latent heat of evaporation of the liquid, and in gasoline like in other liquids, this latent heat has a definite value.

(E) The time factor depends upon (in addition to other factors) the difference in temperature between the liquid and the surrounding as well as upon the ratio of surface to mass.

There are divers other thermo-dynamic variations which will have to be reckoned with under the conditions obtaining, but the device which has been put upon the market under the trade name "Homo" by the Gasoline Motor Efficiency Company, of Jersey City, N. J., is contrived for the purpose of harmonizing the thermo-dynamic relations.

The device comprises a housing with an inlet and outlet orifice suitably flanged for ready insertion in the intake system, as shown in Fig. 1. The inlet orifice discloses a rather coarse wire mesh which will best be understood by examining Fig. 2. This wire mesh is fastened to the peripheral rim of a fan of the disc type.

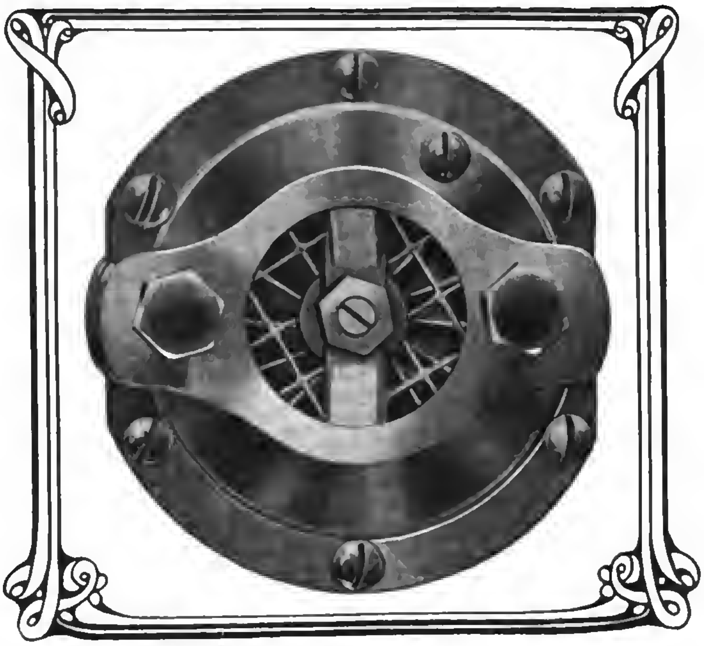

Fig. 3—General appearance of Homo mixer when assembled and ready to go in place

THE FAN IS ROTATED IN THE INRUSHING STREAM

The wire mesh which is attached to the fan rotates at the same speed and the stream of air with its entrained gasoline is intercepted by the wires of the mesh with the result that each globule of gasoline is shattered. This splitting up of the gasoline by mechanical contact takes on all the characteristics of a collision, the smaller particles of gasoline are in a much more receptive condition from the point of view of heat absorption because the surface for mass is greater.

The wire mesh performs an additional function in that it provides a series of paths through which heat is transferred from the region of higher temperature around the periphery and this heat is delivered to the relatively frigid particles of gasoline as they are broken up in the mechanical process. The instrument then performs in a more or less precise way the very functions which are necessary in order to produce a homogeneous mixture. The very process which promotes the change of the gasoline to its vapor state and mechanically mixes that vapor with the atmospheric air is that which aborts carbon precipitations.

IMPROVED TYPE HERZ HIGH-TENSION MAGNETO

IMPROVED just describes the 1910 line of magnetos of Herz & Co., New York City. This pioneer firm in ignition and electrical specialties has made several very important changes in the magnetos, but none of these is such as to be termed radical. That is to say, the magneto proper is the same old magneto but with 1910 improvements.

The whole line has been numbered along a systematic and regular method, which of itself identifies any one member of the series. Thus, the magnetos bear a symbol like this, 5 M 4. This means that it has five magnets, and is for igniting a four-cylinder engine.

All told, the line runs from 5 M 1 to 5 M 4 and 7 M 4. Then the larger sizes are from 5 M 6 to 7 M 6. This translated means that there are five-magnet machines for one, two, three and four cylinders, a seven-magnet machine for four cylinders, also five, six and seven-magnet machines for six-cylinders, making a total of eight different magnetos.

These magnetos have much larger magnet, the armature has been improved with a different winding, thus making the instrument stronger and increasing its efficiency. On the contact breaker the platinum points are larger in diameter and heavier than on the others, and the carbon-brush on the contact breaker is enclosed in a shell, while on last year's magnetos the same was pressed down with a flat spring.

On the four and six-cylinder type magnetos the secondary distributor carbon brushes are revolving against the plain surface, whereas the former types had the wipe principle on the inner circumference of the insulation.

In the line cut below, showing the construction of the 5 M 4 magneto, as well as the contact breaker and the driving end, the details may be remarked. Thus, it will be observed that the ball bearing has been adopted for exclusive use. Thus, the armature shaft runs on two ball bearings, while the distributor shaft is carried on two at the front end. In this same cut will be seen the unusual accessibility of the contact breaker, the cover of which is spring held in place. The spring is pivoted and a touch of the finger is sufficient to turn it aside, allowing the cover to be removed.

At the right, the view of the driving end shows the contact ring and the high-tension carbon brush binding post as well as the connection from there to the rear end of the high-tension distributor shaft. At the left, the details of the contact breaker are in evidence, among these being the increased size of platinum points, the large diameter of the same being plainly seen.

In this same view, the secondary distributor is shown in dotted lines above. The dotted lines also show the wiring to the various contacts from the binding posts. The ball-ended lever at the left is the spark advance lever, and is attached to the segments, which are rotated bodily to advance or retard the spark. In this same view, the component parts of the contact breaker are to be seen, with the much enlarged platinum tips.

The above are the principal points of improvement, although the entire magneto has undergone a general improvement on the minor parts. All parts are interchangeable and the magneto does not require any lubrication; the bearings are sufficiently lubricated to run for a year. Bearings and all other parts are dust-proof covered.

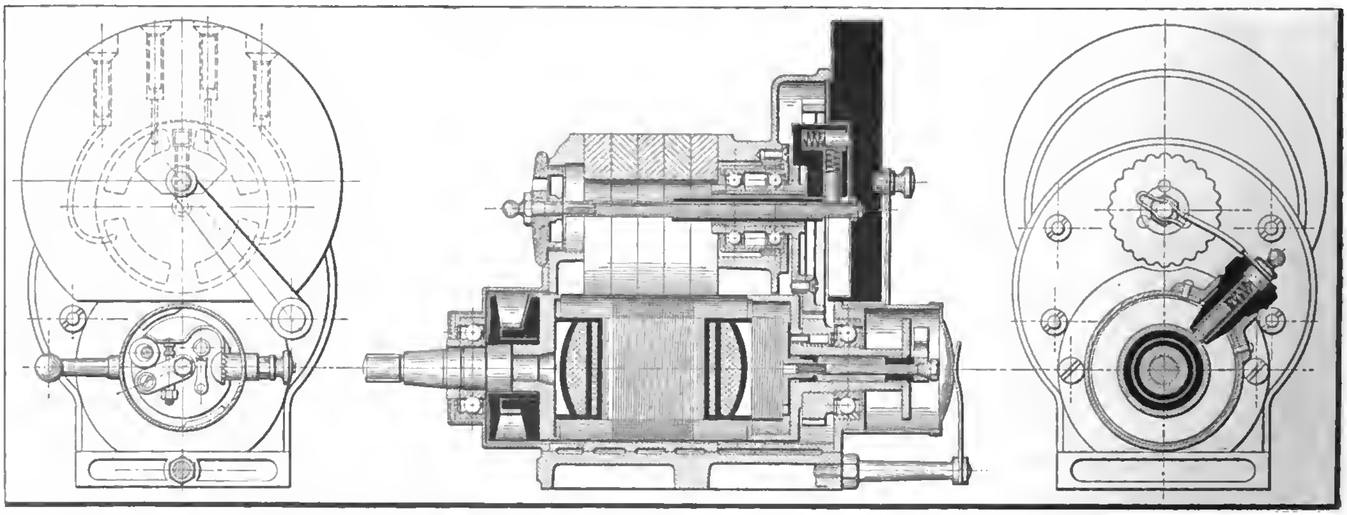
Finally, improvements have not only been made on the larger type magnetos, but also on all smaller types, whereon a much stronger magnet and better armature have been obtained, especially on the two-cylinder 45 degree V-shaped magnetos, on which the armature has been improved by reconstructing the same and changing the winding so that these magnetos are now superior to last year's type.

Below is given a table of the principal dimensions of several of the new Herz Magnetos, these allowing comparison with other makes. In this comparison, nothing very weighty will be found against the Herz product, for they are smaller and lighter than most of the makes now on the market. Service in the past has proved that this design affords an effcient and powerful ignition means. Reports from manufacturers and users have shown that the results are very satisfactory.

This, taken in conjunction with the present-chronicled improvements, bids fair to make the coming year a very prosperous one for the house of Herz, particularly in sales of magnetos.

Dimensions of 5 M 4 & 6 magnetos, also 7 M 4 & 6:

Base, 4 3-8 in. long by 3 1-8 in. wide	5 1-4 in. by 3 1-8 in.
Extreme length, 8 1-2 in.	9 1-4 in.
Base to end contact breaker cover, 1 3-8 in.	1 3-8 in.
Base to driving end shaft, 2 1-2 in.	2 1-2 in.
Base to end bearing box, 1 3-8 in.	1 3-8 in.
Length shaft taper, 5-8 in.	5-8 in.
Large diameter taper, .572 in.	.572 in.
Small end taper, .473 in.	.473 in.
Extreme width magneto, 4 3-8 in.	4 3-4 in.
Height base to top magneto, 5 1-4 in.	5 1-4 in.
Height base to top distributor and terminals, 8 3-4 in.	8 3-4 in.
Same, but without terminals, 7 1-4 in.	7 1-4 in.
Height base to center shaft, 1 3-4 in.	1 3-4 in.
Four hex. cap screws in base, 3-8 in. diam.	4 3-8 in.
End of base to center of screw holes, 11-16 in.	13-16 in.
Side of base to center of screw holes, 5-8 in.	9-16 in.



Three Views of the 1910 Type of Herz Magneto, Improved and Known as Model 5 M 4

VOLTA MAGNETO PRESENTS MUCH REFINEMENT

ARC-FLAME describes the type of the Volta magneto, generating the high-tension current in the armature, without the aid of an external coil. The field magnets, armature, interrupter and distributor, broadly follow standard lines. Other desirable features are the ability to adjust the contact points without stopping the engine; instant accessibility and replaceability of the condenser, and a distributor arrangement which practically obviates the tendency to spark across from one segment to the next. A simple dual system, using the same distributor and plugs, with separate coil for battery use only, completes the list of the more important features of this magneto.

A study of the illustrations, Figs. 1, 2 and 3, will show how the above results are accomplished. The first and most noticeable feature is the location of the condenser 68. Instead of being mounted on the armature shaft behind the interrupter, it is separately contained in a water-tight box, held by one screw and a pin where it may be withdrawn in a moment and replaced by a new condenser, should that be necessary. The cover plate over the armature is permanently sealed, and the armature is therefore enclosed water-tight. Removing the condenser from behind the interrupter permits the high-tension collector ring 65-6-7 to take its place directly under the hard rubber distributor housing 18. The high-tension current therefore goes directly up by the carbon collector brushes 24, 25, to the distributor. The housing fits the casing 29 beneath it so closely as to prevent water from entering and causing an incipient short-circuit.

Fig. 1—Front view of Volta magneto

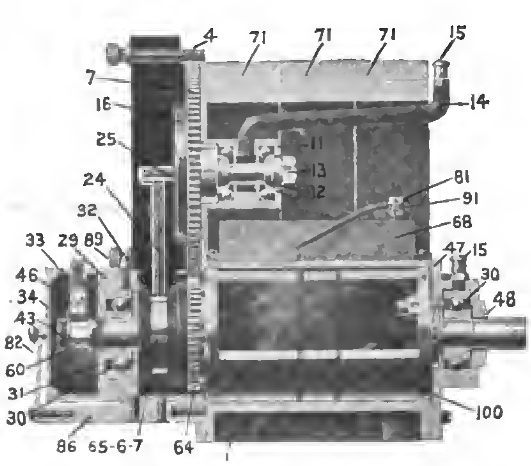


Fig. 2—Section on center line showing constructive details

ARMATURE SHAFT FLOATS ON BALL BEARINGS

Ball bearings 30 are of unusual size, and these bearings are separated by partitions from the rest of the mechanism. The oil cups 15, 32, deliver oil to the bearings, and drain outlets are provided underneath. Even that provision, however, would not be sufficient to prevent trouble from over-oiling were it not for the partitions just mentioned.

The interrupter, which is shown in Fig. 3, with the cover plate removed, differs from some other interrupters in that the cam itself rotates while the "breaker box" as a whole remains stationary. The cam, which is No. 60 in Fig. 2, is of hardened steel and runs against a steel roller 38. The contact screw 84 is stationary, and may be adjusted while the engine runs. The course of the primary current is through a central insulated wire passing through the armature shaft to the insulated button 43, through the flat spring 42 to the insulated mounting 36, thence from the contact arm to the grounded contact point 41. One of the binding posts 45 is connected to the condenser at 91, and the other connects with the ground switch.

The hard rubber housing 18 has no high tension contact segments. Instead, the rotating hard rubber disk 16 has a single T-shaped, inlaid brass segment, receiving current from the carbon brush 25. The cross bar of this segment travels around, making contact one at a time with as many carbon distributing brushes as there are cylinders. These brushes take the place of the usual stationary segments, and the brass segment takes the place of the usual distributing brush. The effect is to increase considerably the insulating distance from one collector brush to the next, since the brushes are much smaller than the usual segments. In this way arcing from one segment to the next is avoided. The clearance between armature and pole pieces is as small as accurate workmanship and due allowance for expansion from heat will permit. After being completely assembled the armature is brought to final size by grinding.

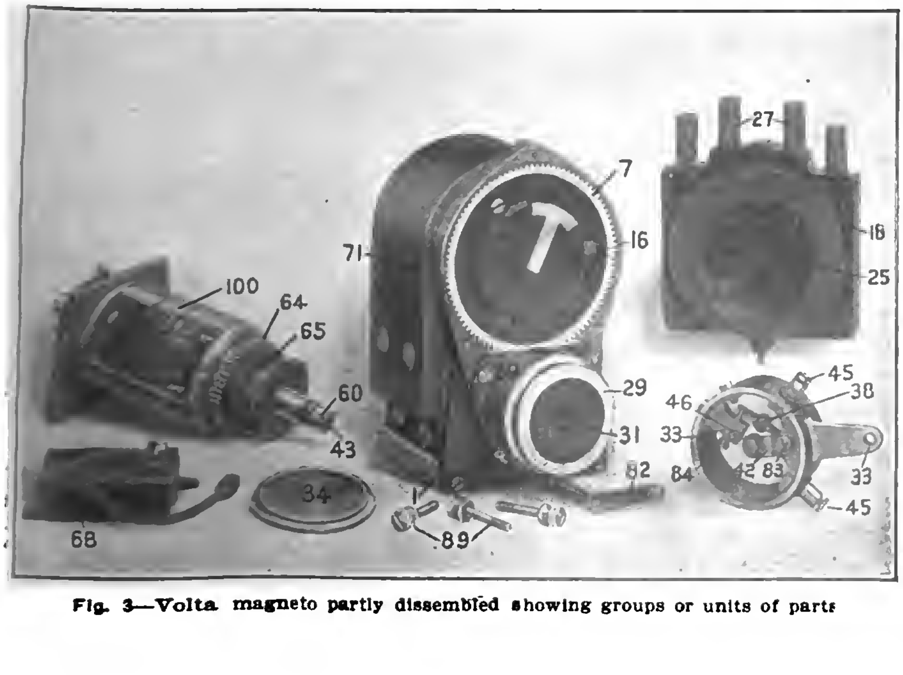

Fig. 3—Volta magneto partly dissembled showing groups or units of parts

Extreme care is taken in the winding and insulation of the armature. An automatic indicator shows the condition of the insulation continuously while the winding is in progress, and if the wire breaks or a short circuit occurs the fact is shown instantly. After winding, the armatures are baked and lacquered in such a manner as to expel every particle of moisture.

The field magnets are imported, and before being used are aged to determine whether they hold their magnetism. After ageing, they are tested for magnetic strength, and if not up to the required standard they are remagnetized and aged again. If the second test shows them to be deficient they are rejected, unless so close to the standard that a second remagnetizing will save them. The material used in the magnets is a special mixture known to produce the best results from the point of view of magnetic density and retentivity. The magnets are aged so that the magnetic performance will be the same for several years of good service.

Urban Scene in Which a Woods Electric Coupe Occupies the Foreground

Makers of electric cars in particular are wont to show their cars in scenes which suggest the comfort and refinement so characteristic of them. Here the Woods coupe, with its elegant lines and luxurious fittings, harmonizes perfectly with the entourage of the residential district in a Western city

Just forty years ago Dr. B. F. Goodrich moved about a dozen pieces of machinery from a half-successful rubber plant in New Jersey to Akron, O., locating on a small piece of ground which then cost $1,800. The machinery was all that was worth moving that distance. This meager outfit was put into a small brick building of two stories. This was the modest beginning of the first attempt to make rubber products in the United States outside of the Eastern and industrially established portion of the country. It was in 1880 that the business was incorporated under its present title, the B. F. Goodrich Company, with a capitalization of $100,000. Up to this time the output consisted of hose, belting, packing and moulded goods.

Shortly, the first factory enlargement was made at a small outlay. Then came another building and then another. Development was rapid. Buildings were added every year. The B. F. Goodrich Company now covers twenty acres with twenty-three acres of floor space and employs 5,000 men. From the modest start in 1870 the resources have grown to over $10,000,000 from its earnings alone.

Postmaster David C. Owen, of Milwaukee, Wis., originator of the idea of using automobiles for transportation of the mails, was in Washington, D. C., last week to report on the results obtained during the third year of this venture in Milwaukee. The general report issue by First Assistant Postmaster-General Grandfield shortly afterward, based on results in Milwaukee Washington, Boston and Indianapolis, is highly favorable to the automobile system. For the Milwaukee system the Johnson Service Company built four special-body cars, with steam power to start with, and this number has been increased to 14 for Milwaukee alone. Gasoline motors are used in the later models.

Among patents recently granted to Milwaukee inventors is one to George L. Odenbrett for a self-starter device for gasoline engines. It will be recalled that Mr. Odenbrett was killed by an explosion of a gas recharging tank in Milwaukee last November. He was probably the original automobilist of the Northwest and ranked high as an inventor. He perfected the self-starting device only a short time before his death. Manufacturers who investigated it had much faith in the device and gave Mr. Odenbrett much encouragement. W. C. Westaway, of Beloit, Wis., is another Wisconsin inventor who has just been granted patents on an ignition device.

The Excelsior Express & Standard Cab Company is about to enter the taxicab business in Pittsburg. It has purchased 20 four-seated, 20-horsepower taxicabs from the Atlas Motor Car Company, of Springfield, Mass., and service will be started in this city February 1. The company's offices will be at 1127-1133 Liberty avenue, opposite the Union Station, and its garage will be at 1133-1145 Liberty avenue. It will establish waiting points at the railroad stations, and will also have direct private telephone communication with the leading hotels. The officers of the company are: President, William H. Keech; vice-president, J. D. Callery; general manager, Joseph Ford.

At an annual meeting of the Swinehart Clincher, Tire and Rubber Company, W. W. Wuchter was elected president, succeeding J. A. Swinehart, the latter being elected vice-president. Other officers are: C. O. Baughman, secretary, and R. A. May, treasurer. Frank R. Talbot was elected to the board of directors to succeed J. O. Surbey. The rest of the board is as follows: Frank B. Theiss, William Byrider, R. A. May, Joseph Dangel, Frank R. Talbot, J. A. Swinehart and W. W. Wuchter.

Within the next four months the police department of Baltimore will have five automobile patrols in service, for the Board of Police Commissioners has placed an order with Callahan, Atkinson & Co., local agents for the Locomobile, for three more four-cylinder, 60-horsepower cars. These cars have a wheelbase of 148 inches. The first one in service, which is used in the central district, makes an average of 60 miles an hour and over, and has climbed high hills at a 40-mile rate.

During the recent snow in Columbus, Ohio, J. Shrum rigged up a motor sleigh which attracted much attention. It was made out of an ordinary sled, equipped with a third runner for steering and with a circular saw, which furnished the motive power in connection with an automobile motor. By an ingenious contrivance the circular saw was so fixed that by a lever it could be raised and lowered, thus adjusting it to the unevenness of the surface of the snow and ice.

It is said that the American Locomotive Company will greatly enlarge its automobile manufacturing department at Providence, R. I., and that it was recently decided to expend half a million dollars for this purpose. A portion of the appropriation will go for new tools and machinery and the balance toward the erection of new buildings. With these facilities this company will be able to double their output of Alco cars.

Indiana, Illinois and Wisconsin are after the Cobe trophy race for 1910. The initial contest at Crown Point, Ind., proved profitable, and the Indiana people feel that it will be hard to find a better circuit. W. C. Moore, president of the Wisconsin State Automobile Association, has a scout car out on the roads near Racine and Lake Geneva, and Frank B. Wood, strong for the Illinois course, announces that he has a circuit admirably suited for road racing.

The Racine Mfg. Co., of Racine, Wis., is now employing 50 per cent. of the total number of workmen in the big shops before the disastrous fire of December 12, which wiped out the buildings. As fast as new machinery can be installed in temporary quarters more skilled men are engaged. It is now definite that the company will remain in Racine, as business men and manufacturers have subscribed enough money to warrant an early start on the buildings.

New contracts will be let in Los Angeles, Cal., for the carrying of the United States mails in automobiles. These will conform closely to the regular screen wagons, of such style and construction as may be acceptable to the department. Each proposal must be accompanied with a statment naming the kind of vehicle to be used, giving a detailed description of the motor and wagon, and also the speed limit permitted for such vehicle in Los Angeles.

The house committee of the New Jersey Automobile and Motor Club will hold a smoker and entertainment on the night of February 10 in Newark. At that time the lecture on aviation will be delivered by Wilbur K. Kimball, secretary of the Aeronautic Association. It is expected that aviation will find the place as a branch of sport with this club, and that a large number of present members will enroll themselves as members of the aviation section.

E. Planche and C. Morel have established a garage and machine shop at 126 East Fifty-fourth street, New York City. All kinds of experimental work will be handled. A special repair-shop department will be maintained with the best French mechanics. Mr. Planche has been connected with the Walter Automobile Company as designer and superintendent.

Hartford is to have another modern garage. It is now under way, and is being built for E. J. Hoadley, on Hoadley place. The building is to be 46 x 90 feet, and will have about 4,000 feet of floor space, with no posts to interfere with the free passage of cars. The new building will be of brick and steel, and the foundations will be made sufficiently heavy to permit of additions.

Yielding to the protests of automobile manufacturers, the projected advance on freight rates which was to have been made by a transcontinental line will be held in abeyance until the next meeting of the Trans-Continental Freight Bureau. This decision means that the rates will remain at $3 per hundred pounds, or about $360 per carload. The increase ordered at a recent meeting would have raised the charge 33 1-3 per cent.

Wisconsin automobile manufacturers have been experiencing great difficulty in their testing divisions because of the heavy snows, general throughout the State of the last two weeks. The snows are the heaviest since 1881. The snow storms, however, have given splendid opportunity for unusual service tests, although under discomfort to the men at the wheels, who go forth with picks, shovels, chains, etc., for emergencies.

It is said that the American Automobile Company, Toledo, Ohio, has purchased Glidden Tour with another one, in which a perfect mechanical and road score will be rewarded with a certificate, and, while no announcement has been made, it is believed that this year the race will be through the Southland, where there is a rapidly developing market for low and medium-priced cars.

St. Louis has a new type of "rubberneck" wagon which has just been placed in commission by the "Seeing St. Louis" Automobile Company. The car is completely inclosed, insuring comfort during the cold weather, and also affording passengers a good view of the sights. Its carrying capacity is twelve persons, while the driver's seat provides for four additional ones.

Reports from San Francisco indicate that the hay market of that city is being seriously affected through the rapid increase in the number of automobiles, both of the pleasure and trucking classes. Livery stables and carriage companies claim to feel the passing of the horse, and one large carriage company was sold at auction because it could no longer make business pay.

George W. Armstrong, a member of the Board of Commissioners of Spokane, believes that the city should adopt auto fire apparatus and will advocate the change, saying that the cost of maintenance is much less than that of horses and wagons. Mayor N. S. Pratt and other officials look with favor upon the plan, and it is likely that it will be brought to a successful conclusion.

The latest thing in Indianapolis is a motor ambulance which, to all outward appearances, is but an elegantly appointed limousine pleasure car. A double floor eliminates all sound of the machinery while the patient is in the car, and, having all the outward earmarks of an ordinary car, the machine avoids arousing the morbid curiosity of street crowds.

A Hupmobile, driven by C. Z. Salling, covered the desert between Los Angeles, Cal., and Phoenix, Ariz., in 27 hours 40 minutes. The distance is 481 miles, a great part of it being heavy going on account of sand, and, owing to the isolated character of the road, it was impossible to secure supplies of any sort during the trip. All were carried on the car.

Chief Grant, of the fire department of South Bend, Ind., in his annual report renewed his request for an automobile chemical engine for the department. He recommends the purchasing of an automobile chemical engine equipped with two 60-gallon tanks and two sets of 1-inch hose, so that two leads could be worked at one fire.

"The Firestone Trio" is the title of a handsome art panel calendar which is being sent out to the trade by the Firestone Tire & Rubber Company, Akron, Ohio. It is 16 1-2 x 34 1-2 inch in size, lithographed in twelve colors, and has a large calendar pad, making it especially suitable for garage, salesrooms and office use.

In the future all automobiles owned by the city of Cleveland, Ohio, will be painted bright yellow with blue trimmings. It is expected that this striking and distinctive coloring will serve to give city cars a right of way, and, in addition, it may prevent unauthorized pleasure excursions and joy rides.

It is reported that plans are well under way by the Mitchell Motor Car Company for beginning the work of manufacture of taxicabs. According to Superintendent J. Bate, specifications for a taxicab which will attract considerable attention will shortly be made.

The "Flag to Flag" automobile contest and international event for motor cars and motor cycles will this year be run from Denver to the City of Mexico. The Wahlgreen trophy will be given the winner. The run will be carried out along the lines of the Glidden tour.

At a recent meeting of the Goshen, N. Y., Board of Trade it was decided to develop a Coates-Goshen automobile, and $150,000 was subscribed by individual members of the Board for a new factory, which will have an output of 150 cars a year.

A number of business men in Carlisle, Pa., have announced that they are about to establish an up-to-date garage and auto business. They will not only cater to the local trade, but will also have branches in several other towns and cities.

The board of trade in Little Rock, Ark., is backing a movement to convert the Clinton Park tract in that city into a speedway. The plot contains 106 acres, and, by incorporating a loop, a course 3 1-2 miles in length can be laid out.

The motorists of Texas have organized a State association and are now pushing a campaign for membership. Indications go to show that this association will become powerful among the automobile bodies of the country.

It is said there will be erected and made ready for use at the next Lakewood, N. J., season an automobile racing course which will cost at least $500,000. The course will be 8 miles in length and complete in every particular.

The Mitchell old model automobile, which was commandeered in San Francisco by General Frederick Funston at the time of the earthquake, is still doing service in that city, and bids fair to last many years.

Matt Weber, of LaCrosse, Wis., and A. J. Frogue, of Kansas City, Mo., have been granted patents on a tireless wheel for automobiles, based on the internal spring principles. Spokes are interchangeable.

The Monon Railroad Company will build an immense shed at Louisville, Ky., for the purpose of loading and unloading automobiles. Plans for the construction have already been drawn.

The Ohio State Highway Commission has filed estimates for the needs of the department for road improvement for 1910. It asks for $880,000, or $10,000 for each of the 88 counties in the State.

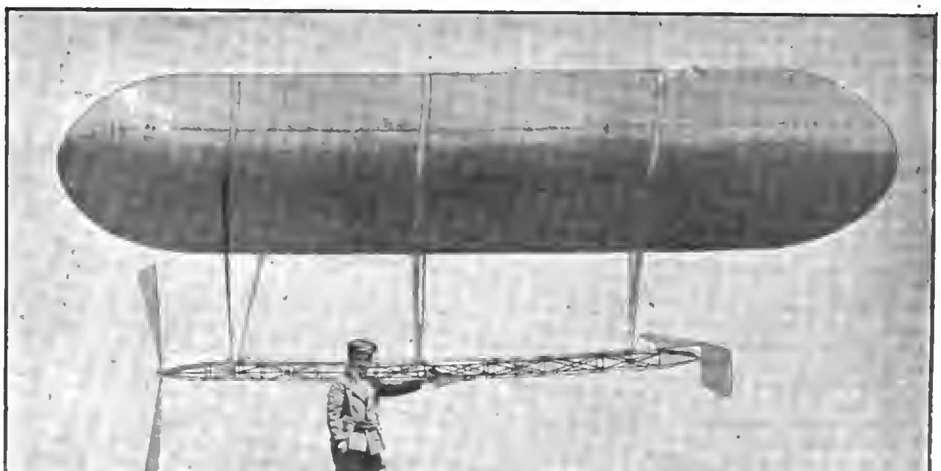
It is reported in Syracuse, N. Y., that an automobile stage route will be established between Seneca Falls and Ovid. A passenger and express service, it is said, would pay.

A recent chauffeur strike crippled the Brooklyn, N. Y., Taxicab Company and left that borough taxiless for quite a while.

The People's Natural Gas Company, of Wilkinsburg, Pa., has purchased a heavy motor truck for its deliveries.

COMING PHILADELPHIA AUTO EVENTS

The Quaker City Motor Club, of Philadelphia, is planning a number of events which, from a social and racing standpoint, will probably eclipse the efforts of 1909. The racing factors for this year will include the famous Fairmount Park race, several track meets, road-ability running, and other events to be decided on later. Track meets are booked for June 4 and August 6. They will be held at Point Breeze track. The Fairmount Park race will be held October 8.



Model of Dirigible Balloon Which Uses Hartford Rubber Company's Fabric

The dirigible is the work of a youthful resident of Hartford who gives promise of becoming a notable inventor. Although hardly of man-carrying size, or even of a size to carry its constructor, it can travel at fairly good speed and is readily controlled from the ground

Packard Testers Snow-Bucking on Grand Boulevard, Detroit

The recent heavy snowfall blocked the streets, and it was necessary to clear some of them immediately so that the fire department might not be hampered. In this work the ubiquitous testers made themselves of great service

The Love Garage Company, of Columbus, Ohio, a new corporation which handles the White, both steamer and gasoline, and the Cole "30" in central Ohio, has moved into the new building which was built especially for a sales agency and garage. The structure has two floors, with a total of 15,000 square feet of floor space. James P. Love is president; Fred E. Love, general manager, and M. L. Love, secretary and treasurer. C. W. Cain, formerly with the American Auto Company of Columbus, becomes sales agent for the Love company.

One hundred and eighty dealers of the Pence Automobile Company, of Minneapolis, Minn., operating garages throughout Minnesota, North and South Dakota, and Montana, paid a visit to the plant of the Buick Motor Company, at Flint, Mich., at the opening of the new year. The trip was made in a train of nine Pullman cars, and two days were spent by the visitors in looking over the works and in enjoying the hospitality of the Buick Motor Company.

A large repair shop will be opened in Boston by the E. R. Thomas Motor Co. This company is realizing that any car, no matter how well it is cared for, needs occasional adjustments and repairs, and so its building on Stanhope street will have a corps of expert mechanicians whose duties will be to make adjustments and give advice as to the running and maintenance of cars. Much of this service will be rendered free of charge.

When the Salt Lake City Automobile Show is held there will be among the exhibits a six-cylinder Franklin with which George T. O'Dell and party at Salt Lake City recently penetrated some of the coldest recesses of the Alps. It is said that in the chilliest of altitudes the car had no freezing trouble. With this car the same party climbed to within a mile and a quarter of Mt. Vesuvius.

Within the past 60 days the Simplex Motor Car Company, of Mishawaka, has added $60,000 worth of new machinery to its plant in order to take care of the orders ahead for its product. It is the intention of the company to turn out 350 complete cars in the next year, as compared with 100 last year. Salesrooms have been opened in New York City at Broadway and Fifty-eighth street, in charge of S. J. Wise & Co.

A partial reorganization of the Smith Automobile Company, Topeka, Kan., has been completed and an additional working capital of $100,000 provided to enable them to take care of the demand for cars. The new officers are O. H. L. Wernicke, Grand Rapids, Mich., President, succeeding Dr. L. Anton Smith, retiring. Walter L. Smith will take care of the distribution.

The New York Mica & Mfg. Co. recently purchased the plant and equipment of the Auburn Mica Company, of Auburn, N. Y., and will make a specialty of mica spark plugs. The new plant is the largest in the country for the manufacture of this article. The company will continue to manufacture the "Auburn" plug, and will add the "Wright" aviation plug especially designed for aeronautical motors.

In order to satisfy himself that the Moon "30" is as powerful on the road as under dyanmometer tests in the factory, Stewart MacDonald, vice-president of the Moon Motor Car Company, drove a $1,500 car from St. Louis to Washington, Mo., and back, a total distance of 150 miles. The test was entirely successful and not a tool was touched.

The Rainier Motor Company, holders of the $10,000 trophy, will place it on exhibition in a selected list of cities in which the feat of the Rainier stock car has created most interest. It will be in the custody of two attendants and a representative of a well-known detective agency. Boston, Philadelphia, Chicago and other large cities will be included.

The Hartford Automobile & Boat Supply Company has filed a certificate of incorporation with the Connecticut Secretary of State. The purpose of the concern is to manufacture and sell automobiles and motor-cycles. The capital stock is $50,000, of which $4,000 is paid in. The incorporators are T. Edward Oakes, William J. Rabbitt and Geo. J. Stoner, of Hartford.

The Boston Offices of the United Vehicle Company have been removed from State street to 107 Massachusetts avenue, this latter address to be the local headquarters of the concern. The company has purchased a factory at Woodville and will erect new buildings to be used as factory offices. The product of their plant will be known as United trucks.

Fourteen carloads of steel for the new plant of the Corliss Motor Co., of Corliss, Wis., the $1,000,000 concern formed to produce the former Owen Thomas Six, have already arrived at Corliss and several carloads are coming daily. The owners of the company are also proprietors of several big steel mills in the vicinity of Pittsburg.

It is stated that plans have been completed for an up-to-date garage to be built by H. W. Brown on Water street, Albany, N. Y. It is estimated that 100 cars can be accommodated on the ground floor. The second floor will be divided into sales and storage rooms, while arrangements will be made on the roof for the landing of airships.

The Public Automobile Service Corporation has filed articles of incorporation at Newark, N. J. Its object will be to operate a taxicab service wheresoever it is required. Wm. R. Buehler, of New York, is said to be the principal incorporator, while Chas. E. S. Thorn, of Newark, N. J., is mentioned as the local agent.

A new car is to make its appearance in Pittsburg, Pa., in the shape of the Ohio "40," made by the Ohio Motor Car Company, of Cincinnati, Ohio. The new machine is to be handled by the Park Automobile Company. The company was recently reorganized by J. C. Armour, H. G. Knapp and Major A. G. C. Quay.

A new firm in the automobile world of Syracuse this season is that of Morrison & Smith, Syracuse, N. Y., who have opened an agency at 109 South State street, where the National and the Palmer-Singer may be seen. Charles J. Roehm, who for some time has represented the National, has taken up work for the new firm.

The Continental Caoutchouc Company is offering a dual demountable rim on which two pneumatic tires are fitted, making four tires on the rear wheels. These rims are designed for heavy trucks and commercial cars. This rim affords quick tire changes and any style clincher tire can be used on it.

The Buick Motor Company, Flint, Mich., has filed articles of incorporation and a statement to do business in Wisconsin. The capital stock is given at $500,000. This is the formal step necessary to the establishment of a branch in Milwaukee. George P. Hewitt, Matthews building, is the manager.

Carson, Pirie, Scott & Company have decided to use the Rapid automobiles for the transportation of goods from warehouse to delivery stations. This firm has already received three 3-ton trucks; more trucks of this type, as well as several 1 and 2-ton wagons, are scheduled for future delivery.

C. Roy Clough, manager of the Columbus, Ohio, branch of the Charles Schiear Motor Car Company, has placed the following sugabencies in Ohio for the Hupmobile: Kenton Auto and Electric Company, Kenton; Walter W. Wood, Marietta; Fritz Bros., Zanesville, and Fritz Bros., Cambridge.

The Pittsburg Automobile Company, now capitalized at $50,000, which has removed to Baum street, East End, has leased its former location at Seventh avenue and Grant boulevard to Leo Kaufman, who will conduct a large establishment in auto supplies and auto oils.

The Richards Iron Works at Manitowoc, Wis., is experimenting in the manufacture of motors for commercial and pleasure vehicles, and on the success of the experiment depends the matter of the establishment of a large plant for the construction of complete cars and trucks.

The first automobile ever made in Findlay, Ohio, will be ready for inspection about March 1. It is now being assembled in the Findlay Carriage Company plant. The car will be a five-passenger with a 124-inch wheelbase of 55 horsepower, and with a speed limit of 60 miles an hour.

The Eastern Automobile Company, of Bangor, Me., will open a new sales, storage and repair room, conducting a regular garage business and handling accessories for the wholesale and retail trade. The Oldsmobile, Oakland, Overland and Buick will be represented.

The Francisco Motor Car Company, Columbus, organized recently to take the Central Ohio agency for the Ohio, has located an office at 338 North High street. A salesroom will be leased later. The company is a partnership, consisting of J. B. and C. M. Francisco.

The E. M. F. car will be represented in Indianapolis by the Reliable Auto Exchange, of 820 East Washington street. The company has obtained an option on a salesroom on Massachusetts avenue, and will probably occupy the new quarters in the near future.

Harry B. Sims has been appointed sales agent for the Charles S. Schiear Motor Car Company in Columbus, Ohio. He will pay particular attention to the Hupmobile and Velie lines. Mr. Sims was formerly secretary of the Columbus Automobile Club.

The Bellevue Automobile Company has been formed by George J. Kurtz, J. H. Ehrhardt, Alton Hamilton, William Bittel and Louis Appel, and will start in business at once in Bellevue, Pittsburg's most aristocratic North Side suburb.

The Bruck Automobile Selling Company, Trenton, N. J., has been incorporated with a capital of $30,000. The incorporators are Norman P. Bruck, Edwin H. Steel and Levy H. Drisdon. This company will conduct a general automobile business.

The Empire Tire Company, of Trenton, N. J., has secured the service of J. M. Shackleford, who will manage the New York uptown branch at 73d Street and Broadway. Mr. Shackleford succeeds Marcus Allan, recently resigned.

The Crest Motor Car Company, Cleveland, Ohio, is to handle the new Warren car, manufactured in Detroit, Mich. The company is to open up headquarters on Euclid avenue, under the management of Messrs. Bunnell & Bishop.

The Mauser Auto-cab Company has been incorporated in Youngstown, Ohio, to do general taxicab and motor business. According to A. E. Elkins, who is to be manager of the company, a line of Cadillac taxicabs will be used.

The Colorado Studebaker Vehicle Company, of Denver, has a salesroom which is said to equal the best salesroom in the United States in appearance and lighting. It is one of Denver's show places.

The Cumberland Garage, of Brooklyn, will handle the Speedwell and Velie cars in that city. The garage company is composed of Alfred Witmarth, ex-president of the Long Island Automobile Club, and W. L. Gray.

The Thomas Company have established a direct branch of their business in Boston. C. S. Henshaw is the Eastern manager. This concern is located in the Back Bay section.

C. M. Blair, of Bartlett, Texas, will in the future handle the Great Western "30s" exclusively. William M. Crow, Millersburg, Ohio, will handle this same car in Holmes County, Ohio.

The Standard Motor Car Company, of 614 North Broad street, has just made a contract with the Velie Motor Car Company, of Moline, Ill., to handle the Velie in the Quaker City.

C. H. Davis, a well-known automobile man, of Alameda County, has been appointed agent for the Cartercar Automobile Company in this city, and is shortly to establish headquarters on 12th street.

PERSONAL TRADE MENTION

George Robertson spent a busy day last week at the factory of the Parry Auto Company at Indianapolis, for which he is the New York agent, in association with H. C. Mergenthaler. He made a careful inspection of the Parry models under the various stages of construction, and expressed himself as well pleased. The Parry plant is now working 600 men and turning out on an average of 18 cars a day.

A. R. Van Antwerp has become president of the Van Automobile Company, of St. Louis, vice C. F. Lorenz resigned. C. E. Darrow will be associated with the company as secretary and treasurer. Don A. Livingston will remain as head salesman, and C. E. Weaver, foreman of the garage, will be retained.

George W. Demack, who has been connected with the Revol Company, New Orleans, La., is planning to go into business on his own account. He has already selected a site for his building, and work is to commence shortly on the erection of a first-class garage and repair establishment.

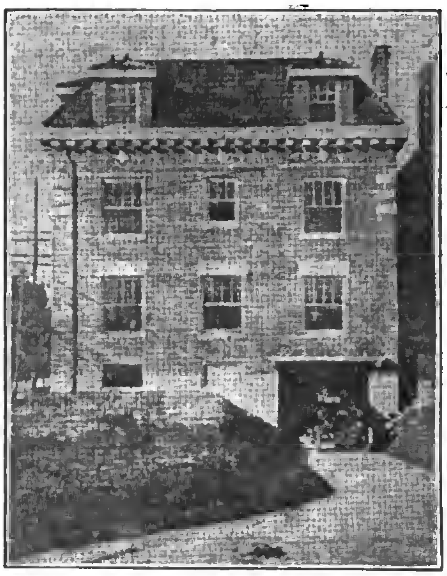
George L. Dorr, president and manager of the United Motor Company Agency for the American and Sterling cars, has leased quarters in New York for an Eastern branch of the concern. This concern has contracted for the entire output of the Sterling. They have placed 61 agencies.

W. H. Dotzaur, of Ilion, N. Y., has been appointed superintendent of the automobile hub department of the Weston-Mott Company, of Flint, Mich. Mr. Dotzaur has been connected with the Remington Arms Company in various capacities for several years.

H. C. Gottfried, manager of the General Motor Car Company, St. Louis, has sold his interest in the concern to J. H. Hutchison and S. H. Kohn, stockholders in the company. This leaves the two latter named in full control of the concern.

W. F. Plastine, of Seattle, Wash., has been appointed manager of the electric sales and garage business of the Studebaker Automobile Company. He was formerly with the Baker Motor Vehicle Company of Cleveland, Ohio.

J. N. Willys, of the Overland Automobile Company, Toledo, Ohio, has purchased the Payne shops in Elmira, N. Y. The plant is to be devoted to the manufacturing of various parts for the Overland cars.



Combined Residence and Garage

Dr. R. Y. Henry's new home on South Grand avenue, St. Louis, has a garage in the basement, thus solving the garage problem once and for all. In the photograph the doctor is shown driving out in his KisselKar

C. F. Frith and Charles G. Short, formerly of Wamego, are to go into the automobile general garage business in Topeka, Kan. Work has been commenced on the erection of an automobile plant.

MANY NEW CONCERNS IN OHIO

COLUMBUS, O., Jan. 25—A number of new concerns have been organized in Columbus to act as agents for cars and to do a garage business. The Francisco Motor Car Company will handle the Ohio and will be at 338 N. High st.

The Ohio Auto Company has been incorporated with a capital stock of $20,000 to take over the garage business of R. L. Patterson at 121 South Third street. Mr. Patterson recently purchased the business from F. H. Lawell. The incorporators are R. H. Kissinger, F. S. Armstrong, R. L. Patterson, Kerr R. Hosey and Theodore A. Patterson.

The Spangler Automobile Company of Circleville, Ohio, was incorporated with a capital of $10,000 by William I. Spangler and others to operate a sales agency and garage business at that place.

The Cleveland Speed Indicator Company was incorporated recently with a capital stock of $5,000 by William H. Marlatt and others to manufacture a speedometer.

The Booth Dismountable Rim Company of Cleveland was incorporated with a capital of $50,000 by W. N. Booth and others to establish a plant for the manufacture of auto rims.

E. H. Huffman, who has been conducting an implement store at 114 East Town street, Columbus, has taken the Central Ohio agency for the International Automobiles and also the commercial car manufactured by the International Harvester Company. The concern will sell roadsters and light delivery wagons.

G. D. Wilson, of the Norris-Toledo Motor Sales Company, of Toledo, has placed the Central Ohio agency for the Parry car with E. C. Barr, Columbus, who has been operating a supply store and motor cycle agency under the name of the Franklin Cycle & Supply Company. He now has the Parry and Demot cars.

INDEX TO ADVERTISERS

CHICAGO will witness the opening of the Ninth Annual Show of the N. A. A. M. at the Coliseum on the 5th proximo, and from indications, with a precision as to time, which would serve as a standard for the "Twentieth Century Limited" to go by. There will be 78 makes of automobiles, and in some cases several models of the respective makes on view, they coming from the Licensed Association for the most part, the A. M. C. M. A. to a considerable extent, and a few outsiders, to swell the list. Pleasure vehicles of the gasoline type will represent the bulk of the exhibitors, but electric vehicles will also be in greater presence, and as to commercials, there will be enough of them to adequately indicate that this phase of the automobile industry is now coming into its own.

Those who may not have paid attention to the growth of the automobile industry, would scarcely be able to realize just what this show represents. From the baker's dozen of exhibitors who braved the public at the first show, to the stupendous array of this, the ninth annual exhibition, represents, when the truth is told, the difference between less than $100,000 as the value of the first year's product, and $500,000,000 which is a fair estimate for the present year, counting the money which changes hands in the conduct of the automobile business which would not change hands otherwise.

Between 1908 and 1909, according to the A. L. A. M. records, the automobiles produced by association members increased 130 per cent., but 1910 over 1909 will show an increase, in all probability, of 200 per cent., which figures show absolutely nothing of the increase in quality of the cars produced from year to year. This question of quality is sufficiently broad in its aspect as to include in its makeup a decided advance in the methods of fabricating steel, a wide variation in the details of the production of castings, and as to machine tools, they to-day, as the direct result of the demand of automobile makers, are so much more capable that it is quite impossible to make an estimate which will be believable if it portrays the facts.

Measuring this exhibition in terms of the prosperity which it has engendered, it would be enough to point out the influence it has brought to bear on the machine tool industry alone. It has been conservatively estimated that the value of the new machine tools which were brought into Detroit alone, to satisfy the automobile requirement, was not far from $85,000,000. It is a well-established fact that the price of a machine tool is probably a good half of the cost of placing the same in operation, considering the jigs, fixtures, and appurtenances which are essential to its proper use. Taking this as a basis, the machine tool builders of this country were benefited directly to the extent of $170,000,000 by contact with the automobile builders in the city of Detroit.

While it is true that something like 50 per cent. of all the automobiles made come from Michigan, within the measure of a comfortable trolley ride from the heart of Detroit, this is not to say that the value of the automobiles turned out in Detroit and vicinity represents half of the total valuation. A fairly conservative estimate of Michigan's *pro rata* of the total automobile business, as measured in dollars, lies somewhere between 35 and 40 per cent., and considering some percentage within these limits, it will then be possible to estimate as to just what the National Show at Chicago represents in the automobile business as a whole, taking it as it is found to-day in America.

OTHER AND IMPORTANT DISTINCTIONS TO BE MADE

This year the automobiles which are being produced are more nearly in accord with theoretical standards by far than they were even last year, the difference is sufficiently marked as to be self-evident to even a casual observer, and the improvements wrought are in all fairness the reward which comes from closely studying the little details all along the line, whereas in some of the earlier efforts, going back perhaps a year or two, much of the then alleged refinements decamped with the glisten of the varnish, which probably did serve as a coat over the last effort of the rubbers in the process of finishing the car in the factory paint shop.

Exterior finish, in former times, covered a multitude of sins, and convinced buyers in many cases. When purchasers were obdurate their fancy was excited by the dexterity with which the family crest was transferred to a convenient panel, nor did they ponder long over the quality of the machinery equipment, believing, perhaps, if they furnished the chauffeur a leather coat he would find it agreeable to lie on his back beneath the car and gaze longingly at the stars above.

It is a little strange, perhaps, that the quality of the automobiles from the mechanical point of view, improved in the same ratio that overdone exterior finish disappeared. The underlying reason for the changes wrought, lies in the increased quality of the mechanical equipment, and the entire absence of any attempt to disguise lack of quality by an attractive coat of paint. As a matter of experience, it is now fairly proven that the patrons of the industry are a discriminating set and they appreciate quality in the equipment as a whole, and the further fact that some of the earlier creations lacked in comfort-producing details about in the same proportion as the machinery equipment at that time verged away from stability.

OLDER PROBLEMS BOWED TO INTELLIGENT TREATMENT

The National Show, for the very reason that it will have in its makeup all the excellent examples from the several camps and clans, will prove of exceeding value to those who take an interest in the growth and prosperity of the industry, because it will bring together the several schools of design, and accentuate for purposes of inspection, the advantages therein contained, but if some of the schools are lacking in essential particulars, the facts will at once be rendered apparent.

In addition to the automobiles, there will be the accessory divisions numbering in their classifications parts makers, who, to a very large extent, are as the foundation for many of the superior examples of cars. These parts makers serve as specialists in their line; they do some one thing, and that they should become experts, is but natural. Some of the parts makers work to drawings and specifications at the command of the companies who employ them, in which cases, they assume no responsibility beyond that of completing the tasks in conformity with the drawings and specifications. Others of the parts makers, preferring to grow a reputation of their own, offer designs in distinctive form, and being experts from force of habit, are able to convince the makers that they can deliver a better product for less cost.

An innovation will be introduced in the opening ceremonies of this show. It has long been the custom to drag into this performance some political luminary, who knew little and cared less about the automobile business. At Chicago, the idea will be tried of opening the show without any formal ceremony whatever. General Manager Miles will quietly give a signal at the hour of 2:30 Saturday afternoon, at which signal, the show completed on time, will be opened to the public, with no further delay. In proof that the show will be ready, the committee say the buildings were at their disposal two days ahead.

N·A·A·M· SHOW COMMITTEE

WHEN the show opens at the Coliseum on the 5th proximo, General Manager Samuel A. Miles will have completed the most stupendous task which was ever undertaken within the confines of the great metropolis of the Middle West. Every inch of available floor space mounting up to 89,000 square feet, will be covered by some interesting phase of the greatest industry known to modern man, not forgetting that it is the self-contained handywork of but ten or eleven consecutive years. The Coliseum and the First Regiment Armory combined are not nearly large enough to hold the aspirants to exhibition honors, and the committee has been beset at every hand, and with consuming persistance, by the automobile hosts, who evidently evinced a desire to make the Ninth Annual event of this character at Chicago so national in its scope as to represent the high water mark.

The scheme of decoration has been put forward on a most comprehensive basis, departing from the conventional, and following in the footsteps of Dame Nature to the last degree. Nearby Wilmette was drawn upon for enough black oaks to make a forest, to serve as a background for the wares of the 257 exhibitors, and the committee decided that the Annex basement should be devoted to cars rather than to accessories, so that the actual number of exhibitors this year will have fallen below the number which were accommodated when last the show was there. This difference comes from the mere fact that automobiles take up more room, but it was deemed expedient to make an abiding place for as many automobile exhibits as possible, even though to the detriment of the accessory division. Some of the accessory makers, having failed to successfully negotiate positions for themselves, were able to double up with their more fortunate neighbors. The Pittsfield Spark Coil Company, for illustration, are in this class, they having procured a position by annexing part of two separate allotments in the gallery, and by the simple process of pre-empting the unused space which forms a strip on the two sides of the party line.

When the show opens, considering the situation as it stands, the Holsman Automobile Company, of Chicago, will probably be the only concern which will fail to put in an appearance, which action on the part of this company is due to its having gone into the hands of a receiver after making application for space. The waiting list numbers about 130 separate applicants for space, and after having squeezed in four makes of cars, putting them in the basement, Manager Miles seems to have reached the conclusion that ingenuity no longer applies. The four additional makes of cars which were accommodated by dint of an excessive display of ingenuity were the Diamond T Motor Car Company, Monitor Auto Works and A. C. Clark Carriage Company, all of Chicago, and the Springfield Motor Car Company, of Springfield, Ill.

The entire situation, summed up in a word, portrays a condition of the utmost harmony, and the consensus of opinion as voiced by all who have had dealings with the committee leads but to the one conclusion, *i.e.*, the undertaking is a large one, and it demanded treatment at the hands of veterans, which it received without stint.

The members of the committee, as pictured here, are so well and favorably known to the automobile fraternity and the wide world that introduction would be absurdly superfluous. Chairman A. L. Pope, in his collaboration on this occasion, has rendered up his customary distinguished **services, and the veteran of the Winton plant, Thos. Henderson, lent the guiding influence of a steady hand, which was none the less potent due to the presence of Wm. E. Metzger on the committee.**

The prospects of a successful run for the show are assured, in view of the wide interest which is taken by the citizens at large, which is backed up by the "Old Guard" of autoists of which Chicago and vicinity numbers a legion. As a further evidence of the wide interest taken, the Central Passenger Association has granted a rate of one and one-half fares to all visitors to the Chicago show, provided that no fewer than 1,000 present their certificates to the railroad authorities at the Coliseum. The rate is granted on account of the convention of the A. A. A., rather than as a direct result of the show holding, but membership in the A. A. A. is not necessary to participation in the benefits.

SOME STATISTICS OF THE CARS

ESTIMATED PRODUCTION BY STATES

States	Cars	Value
Michigan	150,000	$190,000,000
Ohio	44,000	64,000,000
Indiana	35,000	50,000,000
New York	12,000	39,000,000
Pennsylvania	6,000	15,000,000
Illinois	7,000	12,000,000
Connecticut	4,000	12,000,000
Wisconsin	8,000	11,000,000
Missouri	4,000	10,000,000
Massachusetts	3,000	7,000,000
Scattered	7,000	9,000,000
Total	280,000	$419,000,000

COUNTING the value of the automobile industry is a process which must include far more than a mere statement which will give the number of automobiles in process, or which have been made. In the building of an automobile, it is first necessary to mine the ores of which the materials must be fabricated; then, comes the work of fabrication in the steel mills, the processes in the foundries, and the endeavors in the forges. There are intervening matters to be taken into account, one of which item is that of transportation, and it is reoccurring.

With the materials in sight it becomes rational to consider the purchases of land, the erection of buildings, and the designing of the automobile models. Coincident with these activities, is the question of the machine tools, and they must go through a process which is parallel to that of the automobile proper in which the first effort is at the mines, thence to the smelters, and so on down the line, until the propitious time arrives, when the special machine tools as demanded in the building of automobiles may be priced, ordered, and delivered.

The first model of an automobile, even under the most refined conditions, due to much experience on the part of designers, will be likely to foot up to the comfortable sum of $50,000, which is but the A B C of the undertaking. With the model on the road, and its incongruities noted, it is then wise to undertake the designing of the jigs, tools, special fixtures, by means of which the automobile may be duplicated in quantity, on a basis of interchangeability, bereft of the personal equation, and at a cost which will permit of selling with a difference which will take care of "overhead," selling, and contingent expenses. These fixtures, of which one company alone is the possessor of 90,000, cost all the way from $500 to $5,000 apiece, which, added to the cost of patterns (a detail which might readily approach $100,000 in a decent sized plant) will give a fair insight into the preliminaries of a situation such as this, provided a $50,000 drawing account is added, and a dead labor value of overhead administration charges is not forgotten in the process.

Occasionally, when advertising, and not infrequently in apparently serious statements elsewhere, the point is made that all these expenses have been obviated in some specially skilled process which ended in a full-fledged automobile. These statements, if not qualified, have a ring of truth, but to see the situation on a broad basis, is to stumble over the fact that some parts maker, or a whole school of them perhaps, sustained the expenses of exploitation, incurred all the cost as above enumerated, and in some measure this is the kernel peeping out of the shell, which tells the story of the accessory maker and the short cut to success.

If, by a specialized process, plans, patterns, templates, gauges, jigs, fixtures, and facilities in general, may be utilized in a dozen undertakings, then, the preliminaries of these undertakings, severally, will be at a cost somewhat less than the total which might be indicated were each one to operate independently of the other. The advocates of specializing, as accessory makers, claim that they have added materially to the process of standardization, and to the value of the statistics which are now so overgrown that it becomes a difficulty of no small moment to make compilation, and in so far as specialists do add to the stability and value of the product, they are entitled to credit, but all the specialists are not in the accessory plants, nor is a maker of automobiles debarred from specializing merely because the work is confined to the manufacture of a given design of cars.

When the grist comes from the mill, it will be found that the bran and the chaff will be the product as aggregated from the several sets of "stones," and that the statistics of the automobile industry as here briefly put, are the square root of mean

SOME STATISTICS OF THE CARS

square of all the efforts that each little effort will be found in the whole, that none are lost, and that a balanced condition is the real result of this aggregation.

The exhibition of automobile parts and fittings, which is about to be opened as a national event at Chicago, represents, under the circumstances, the whole industry, counting everything from the product of an automatic screw machine to the slab which comes from the hundred-ton press; and it presents in orderly array all the things which are made and which add (taking the present as a basis) $500,000,000 per annum to the wealth of a nation, spreading the same out into the little increments which may be measured in loaves of bread within the reach of those who find it a daily need, more than it can be looked upon in a coupon clipping way by those who are not on speaking terms with the baker for lack of interest.

This same exhibition represents something besides the material things called automobiles. These very statistics carry with them a potential force which is not measured in dollars. The elimination of the horse from streets in metropolitan districts, thins out the staff in the office of the "board of health," reduces the appropriation which is required for purposes of cleaning the streets, suppresses mortality as it is measured hy the insurance companies, and in so far as it is possible to estimate the several advantages in dollars merely to enable the mind to grasp the situation, these dollars must be added to the $500,000,000 already set down as directly due to the automobile industry.

The elimination of the horse as looked upon by the contractor, the grocery man, and the farmer, whose returns are measured in horses sold, as being a serious evil, may have certain justification, but this damage which may be directly traced to the automobile, and which must be considered in connection with the statistics thereof, has a certain offset, and who can tell if the algebra sum of all the increments above and below zero measure, will be anything but advantageous for all concerned. If the contractor finds himself handicapped by a span of horses, it will he because some other contractor who uses automobiles is beating him out, and if the farmer, who found it profitable to raise horses, does not wish to raise automobiles instead, he will have the more time at his disposal for the purpose of raising wheat, and the automobile plow will permit him to turn up alluvial soil from a far greater depth than ever before with less labor, and for his greater advantage.

The humanitarian will accept the coming of the automobile as being the emancipator of the horse, and he will have in his audience a vast concourse of materialists who will undoubtedly find that the automobile is a machine which only has to be fed when it works, which bows to superior intelligence, whenever that rare condition grasps the guiding lever, and wills the way.

Let us pursue another angle which has its bearing on the statistical side of the review of the automobile. The time was when man in his state of savagery moved out from his communal acreage merely if he discovered that some other community was the possessor of something which he did not find in his own small zone, but as he made slow progress across the face of untrammeled Mother Earth, he had plunder in his heart, and it was a good thing for the possessors of what he wanted that the roads were unimproved, so that the uncivilized plunderer of bygone days was impeded by Nature in just proportion to his lack of intelligence. Wisdom hrought the warrior's chariot, and slight improvements in roadways at impassahle spots, but since like begets like, it was not profitable, so it was found, to fight for that which could he had for the asking on a basis of trade, and road improvements naturally followed as one of the accessories of a more civilized state.

GENERAL REVIEW OF THE INDUSTRY

Estimated Number of Cars for 1910, 280,000
Value of These Cars Approximates $419,000,000
Their Motors Will Develop 80,000,000 Horsepower
The Cars Will Weigh More Than 300,000 Tons
Altogether They Could Carry 1,200,000 People
End to End They Would Stretch at Least 650 Miles
Capital Invested In Them Totals $200,000,000
Factories Which Build Them Are Worth $30,000,000
These Factories Cover 2,500 Acres of Land, Total
The Floor Space Used Is 28,000,000 Square Feet
Machinery and Equipment Is Valued at $85,000,000
Workmen Employed in the Industry Number 120,000
These Workmen Receive $80,000,000 Wages Yearly

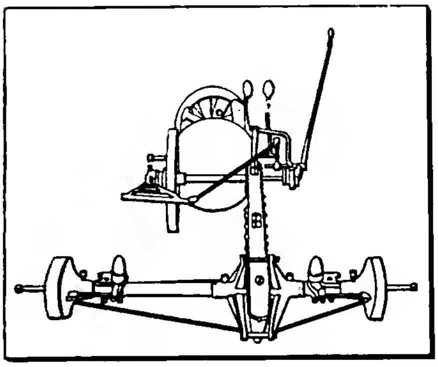
NOTE—Due to a lack of space, two pages of tables, including Steam Pleasure and Commercial Cars, Electric Commercial Cars, and Foreign Cars, have been omitted. These two pages will be reproduced in next week's issue of THE AUTOMOBILE, with perhaps some additional pleasure cars.

PROCESS AND PRODUCT

CONSIDERING the dual display of automobiles as they appeared at the two shows in New York, it becomes something of a problem to decide as to the best descriptive matter to offer for the automobiles which will be exhibited at the National Show, under the auspices of the N. A. A. M. in the Coliseum at Chicago. In some ways the Coliseum Show is much more comprehensive than any other exhibition would prove to be, for the reason that there is a wider range measured in types of automobiles placed in a comparative relation there.

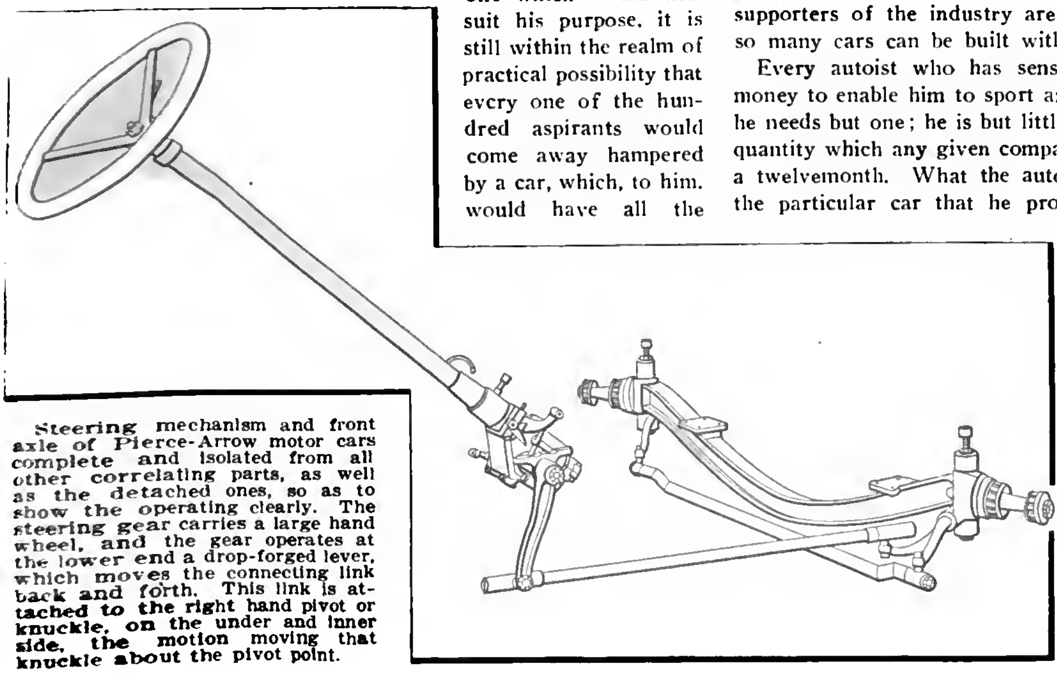


On the Cartercar the drive is by means of frictional discs, thence from the cross shaft to the rear axle by enclosed chain. The cut shows the rear axle construction, the chain-in-oil drive, and the friction transmission, as viewed from the rear. The single lever control is also noticeable, this making for simplicity of operation, as well as simplicity of mechanism. The friction drive allows of as many speeds as there are possible positions.

That exhibitions of automobiles may be of the greatest value to the patrons of the industry is a matter which has long been fairly understood, but it is not always true that these exhibitions accomplish the intended purpose. As an illustration of the point to be made, it is enough to indicate that were all automobiles exactly alike, an exhibition might well be reduced to a single representative of the whole flock, so that unless the display is on a basis which will show the extent of contrast between the several designs, the whole value of the idea will be lost.

The National Show, because it does include a wide variety of types, emanating from the several camps of designers, offers an excellent opportunity to buyers to compare the handiwork of the several schools of design and to determine for themselves the capabilities of the several ideas in view of their wants. It is a matter of absolutely no moment at all as to how good an automobile may be, viewing it in the abstract; its value must be measured in the light of the service required of it by the buyer.

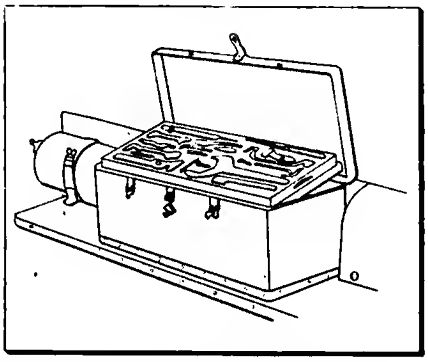
If a hundred separate buyers were to go to the salesrooms of a hundred different makes of automobiles, even conceding that each buyer might find in some one of the cars to be had the very one which would best suit his purpose, it is still within the realm of practical possibility that every one of the hundred aspirants would come away hampered by a car, which, to him, would have all the avoirdupois of a white elephant. Such is the position in which the average man stands toward the complications (as he thinks) of the average automobile, despite the maker's efforts educationally.



Steering mechanism and front axle of Pierce-Arrow motor cars complete and isolated from all other correlating parts, as well as the detached ones, so as to show the operating clearly. The steering gear carries a large hand wheel, and the gear operates at the lower end a drop-forged lever, which moves the connecting link back and forth. This link is attached to the right hand pivot or knuckle, on the under and inner side, the motion moving that knuckle about the pivot point.

IT IS SCARCELY ENOUGH TO EXAMINE THE AUTOMOBILES

Many of the makers of automobiles go to shows with a polished chassis, which is an excellent way of putting the best foot forward. This is not to say that the cars which are shown in the finished state are not provided with a "Sunday foot," but to the average buyer who has no money to waste, seeing is believing, to some extent, at any rate, and if the polished chassis is not to be seen, it becomes necessary to go back of the cars and ascertain how they are made in the shops.



All of the useful and dainty little accessories which appeal to the man and woman of refinement are to be found on the Packard cars. The cut shows the tool box as located on the running board of both the "Eighteen" and the "Thirty." It will be noted that the removable tray of the upper part of the tool box has formed compartments or spaces for each and every tool, making it possible to apply, "A place for everything and everything in its place."

In this treatment, in view of the apparent requirement, it is the idea to show some one feature of the respective makes of automobiles, with the idea of testifying as to the uniformity in the matter of the standard which has been set in the engineering offices of the makers of cars, taking them as a whole, and with the further intention of affording some accentuated detail, which may be found in the respective cars, in order that they will be more readily identified by the prospective buyers.

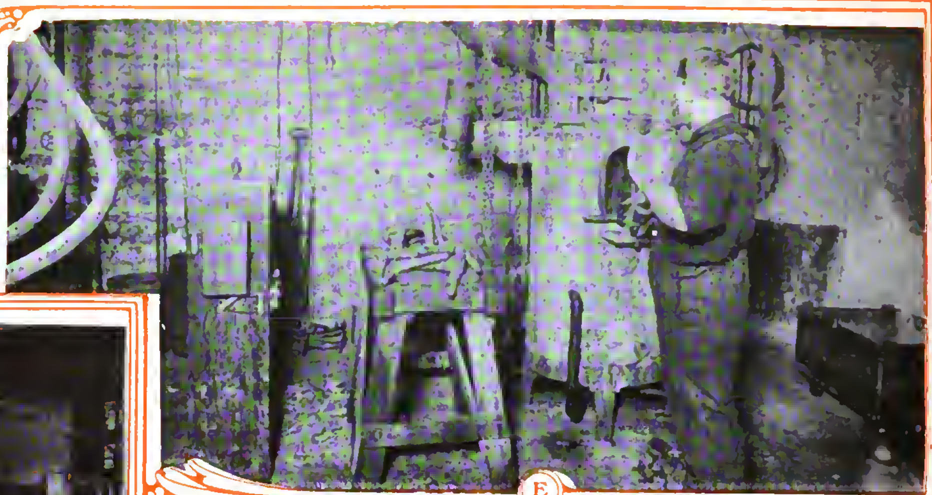
Beyond this point The Automobile has undertaken to illustrate very completely the methods which obtain in the plants in this country, partly with a view to disseminating knowledge of this sort, hoping, perchance, that it will bring to those who need them ideas which may be of more than a little service, and to some extent, perhaps, modify such practices as may not be quite up to the high standard on which the whole automobile situation rests at the present time. Then, in view of the large number of automobiles which are now being turned out at every hand, the supporters of the industry are entitled to know how it is that so many cars can be built without depreciating their value.

Every autoist who has sense enough to accumulate enough money to enable him to sport an automobile probably knows that he needs but one; he is but little interested in the question of the quantity which any given company may succeed in turning out in a twelvemonth. What the autoist really wants to know is that the particular car that he proposes to invest in will be good enough for his purpose, and low enough in first cost to be on a par with the legal tender which he must part company with when he rolls the car away and starts it on the road to history.

The illustrations of shop methods and practices as offered in these pages are the real means by which automobiles are made in a large way, they having been photographed in many plants under the eye of the Editor, taking some 15 weeks in the process, so that

PLATE I.

STOCK AND SELECTION



A—In the Thomas plant, showing drop-forged gear blanks in the foreground and annealing furnaces which are utilized for the purpose of relieving internal strains in order that the gears, after they are sized, gashed and planed, may be cemented, quenched and tempered with freedom from deformation. This cut shows the light, clean place which the modern workman has to work in, as compared with the dark, dingy holes common in earlier days. This is one of the results of a more accurate knowledge of the benefits accruing from hardening, and a more intimate technical knowledge of the processes themselves. They are now very generally practiced, nearly every shop having its hardening room.

B—In the Inter-State plant, showing a muffle-furnace to the right, with a counter-poised door, a quenching bath to the left, in front, and a pyrometer on a stand under the window.

C—Sand blast in the works of Wheeler & Schebler, blasting a batch of carbureter castings, which process removes scale and permits of machining at high speed under conditions which prolong the work between grindings of the cutters. If the carbureter bowls are not to be polished and lacquered a sand blast finish is allowed to remain.

D—In the Diamond Chain plant, showing how women are employed in the process, this particular illustration being that of a cutting-off tool which parts the specially formed bar, into 28 separate blocks, in three minutes.

E—In the Woods plant, using a barrium salt bath for heating parts as steering knuckles to a quenching temperature, utilizing a pyrometer, by means of which the temperature is definitely determined and the quenching temperature is fixed in view of the known quality of the material which is to be manipulated.

they are offered with a measure of confidence which is not dimmed by the fear that the dream of some ambitious publicity agent is taking expression. The illustrations, then, and the brief descriptions which accompany them, should serve a useful purpose is connection with the car descriptions attending, and the only source of regret lies in the absence of illustrations from every plant in the country.

In many of the plants, although they are fitted out after a fashion thoroughly up to date, they were so busy struggling with the output of the year that it was considered inexpedient to permit of photographing the processes, and the probabilities are that a further effort along this line will be undertaken a little later on, when the season's product is more nearly completed. For the present, then, and in view of the opportunities for comparison which the National Show at Chicago offers, the cars there to be exhibited are given brief space (each one of them) in this article, with an illustration of some one mechanical point, and for the rest, the shops behind the cars are exposed in analytical form, by means of reproductions front photographs in 10 double-page plates, with descriptive captions attending.

ALCO RETAINS PROMINENT BERLIET FEATURES

These well-known cars, which are the product of the American Locomotive Company, Providence, R. I., are listed in four regular models, the smallest of which is a 16 horsepower with a landaulet type of body which is obviously a good size for taxicab and town car service. In certain classes of service of the character as above indicated, preference is given to a somewhat more powerful motor in certain localities and the 22-horsepower model is then employed. In touring work, the 40-horsepower model is the most used car, although the 60 has its stout appearance among the "hurry" clan. The three first-mentioned models are four-cylinder, but the 60 is a six. The car which won the Vanderbilt Cup Race last fall, it will be remembered, was also a six. In fact, it was an exact duplicate of the standard and stock car, which any Tom, Dick or Harry can buy, if he but has the price. This, like all Alco motors, has a rather long stroke, that is, it is not excessively long, but on the other hand it is not short as compared with the bore.

F—In the Woods plant, showing a salt furnace which is long enough to take an I-section and raise it to the appropriate treating temperature, uniformly and with great precision, it being the case that the temperature of the bath is regulated by a pyrometer in conjunction with suitable rheostats, and the proportions of the salts are also suitable, in view of the desired temperature.

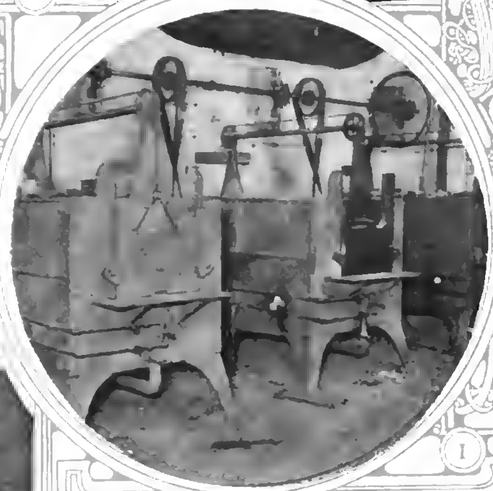
G—In the Diamond Chain plant, showing a woman operator hand-grinding links with such dexterity as to do the work in the minimum possible time, attaining a light surface finish of the hardened, close-grained alloy steel. Women are very widely utilized as employees in this modern chain manufacturing plant.

H—In the Woods plant, showing an open hearth with a salt bath, electrical means of heating, and pyrometer regulation. The operator hardening, short operating levers, while on the work bench at the right may be seen a lot of finished universal joint parts, showing at a glance the wide scope of usefulness of the hardening furnace.

I—In the Diamond Chain plant, giving a glimpse of a battery of muffle-furnaces, of which there are two rows facing, extending for the length of the heat-treating department.

J—In the Thomas plant, showing an operator with an electric buffing equipment, polishing the surfaces of cylinders used on Model M Thomas.

K—In the Rambler plant, making forgings under a press. This large and heavy hammer is seen turning out crankshafts in the rough, the operation being the very last one of the process. In this Wisconsin plant, hammers of the vertical type are extensively used, not alone for large, heavy work, but for smaller and lighter drop forgings.



Alco motors are made with a lengthened stroke as compared with bore, as the following will show:

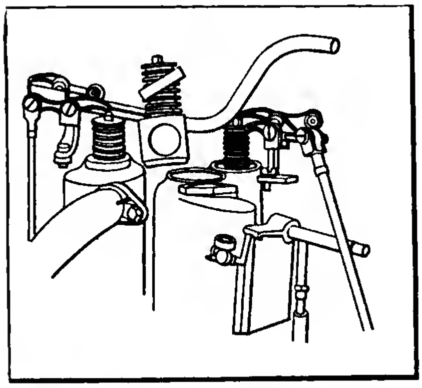
RELATIONS OF CYLINDER DIMENSIONS

Horsepower	Bore	Stroke
16	100	120
22	100	120
40	120	150
60	120	150

The difference in power between the 16 and the 22 is a matter of speed, the bore and stroke being the same in both cases. The difference in power between the 40 and 60 is due to the increase between four and six cylinders.

ANHUT SOLD BY CAR MAKERS SELLING COMPANY

Made in Detroit, and distributed by the Car Makers Selling Company, Chicago, the Anhut "six" is one of the relatively new automobiles which has rapidly forged to the front. The motor is a "Brownell" and was very completely illustrated in The Automobile in the number of December 16, last, with cross-sections showing, among other points, details of design which are at quite some variance from general practice, as a supplementary cam-roller lever which eliminates lost motion and noise from the valve lifts and promotes long life by preventing wear. The oiling system, in this type of motor, is very completely carried out, and the valves, which are in the head, are actuated by a system which is so closely fitted as to run noiselessly, with a special means of lubrication to abort the growth of noise, which is but a matter of defeating wear. The cylinders are cast in pairs, valves are in cages, and the crankshaft, which is of special steel, forged, and reduced from a billet, is flanged for the flywheel and is of excellent proportions. Ignition is by magneto, placed back of the carbureter on the left side of the motor, and the clutch is of the multiple disc type, within the same housing as the transmission gear, which housing is integral with the crankbox. The flywheel is in front and the unit power plant, which is its right designation, is suspended on three points; the rear suspension is centrally located and flexible. The price of the roadster model is $1,750 and the pony tonneau sells at $1,850. Although a comparative newcomer, the excellent impression produced at the start has had its effect, and factory additions are rumored.



One of the distinctive features of the Pennsylvania engines made by the Pennsylvania Auto-Motor Company, Bryn Mawr, Pa., is the use of overhead valves located in a different sort of a cage. This—the illustration not only illustrates it, but also shows one valve and cage removed—is an arrangement which allows of the rapid and ready removal of any or all of the valves and cages for the purpose of grinding in. When removed, the valve may be placed in a vise and ground in.

APPERSON JACK RABBIT ON SPEAKING TERMS WITH FAME

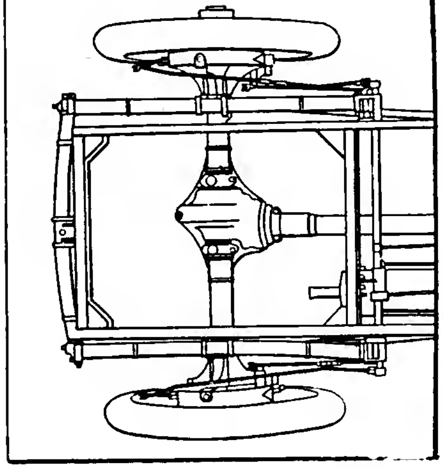
The Apperson cars are made in six models, with a price tag ranging between $2,000 and $4,200. The motors are all of the long-stroke type, and the model 6-40 has six cylinders with a bore of 4 1-2 and a stroke of 5 inches. The cylinders are individual, Bosch ignition is represented by a magneto for the running condition and a storage battery, in conjunction with a suitable coil, serves for cranking and should an emergency arise. In the Apperson cars the clutch is of the constricting band type, and speed changes are, with the transmission system, of the selective order, three speeds ahead for all but the 4-50. The Apperson idea from the economy point of view is to equip all of the models with relatively large tires, which is illustrated when it is said that the model 4-30 weighs 2,700 pounds and has 34 by 4-inch tires on the rear wheels.

BLACK CROW IS WELL KNOWN IN THE CENTRAL WEST

This car is priced at $1,200, has a 24-horsepower motor, is built for touring, seats five, is of the six-cylinder type, with 3 7-8 by 4 1-2 bore and stroke of cylinders, respectively. A Remy magneto is responsible for ignition, but a battery and coil occupy the supernumerary position, and the transmission is by the selective system with three speeds and a reverse. Ball bearings are employed at every point excepting in the motor, and the tires used are 32 by 3, front and rear.

CARTERCAR IS A FRICTION DRIVE AND WELL KNOWN

Model H Cartercar sells for $1,100 with a 25-horsepower, four-cylinder motor and a runabout body. The cylinders are 4 inches square, and the A. L. A. M. rating is 25.6 horsepower. The water cooling is through a tubular radiator, and ignition is cared for by a Splitdorf magneto in conjunction with dry cells and a coil. Lubrication is by a pump which is positive, and the friction drive gives an infinite number of speeds. In connection with the friction system a chain is used, and it is protected by a boot so that the silt of the road has nothing to do with the performance. The road wheels are fitted with 32 by 3½-inch tires all around, and the car weighs 2,000 pounds. The Model L car of the same make has a somewhat larger motor, and sells for $1,600, otherwise it conforms to the well-known Carter type of construction, the advantages of which are adequately proclaimed by many users.

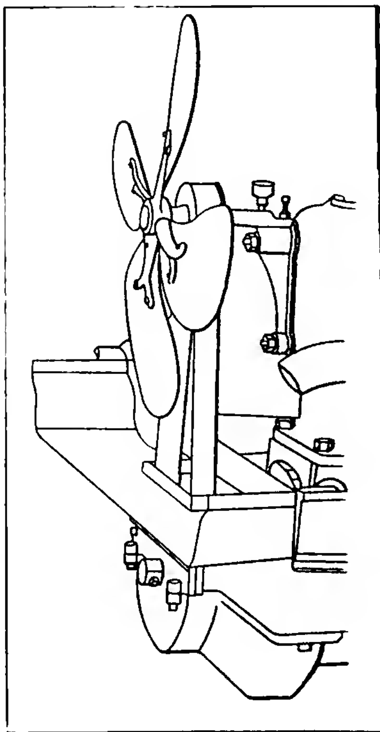


This year, Mitchell produces a "Six" for the first time. The cut shows a top view of the rear portion of the chassis of Model S, as the six-cylinder chassis is called. In this may be seen the arrangement and attachment of the rear spring suspension. As will be seen this consists of a platform spring, the center of the cross spring being firmly fixed to a bracket extension at the rear end of the frame. The side springs are clipped to the axles at the mid-point, and shackled at the front to the spring hanger, and at the rear. The net result is very easy and pleasurable riding.

CHALMERS-DETROIT THIRTY HAS BLOCK CYLINDERS

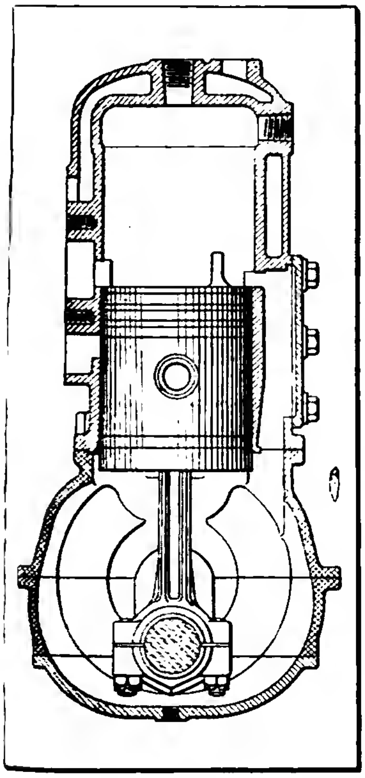
The crankshaft of this motor is short and stubby, which is possible, in view of the block method of casting the cylinders, and two annular-type ball bearings of a proven size are used to support the crankshaft effort. When this type of construction first came across it was questioned by some of the advocates of more bearings for a crankshaft, but the large number of cars which were put out in this way, in view of the excellent service by them rendered, rendered speculation unprofitable. This year the 30 is a considerably larger car than last, the bore of the cylinders being 4 inches and the stroke 4 1-2, is rated at 30 horsepower, and the car sells for $1,500. Ignition is by Bosch magneto at the extra cost, which means that the coil and battery ignition, as normally put on, is on a very substantial basis. The three-speed selective gear is in a case which is an extension of the motor case, thus bringing the power plant, multiple disk clutch and transmission gear into a single housing in conformity with the demands of a unit system. The wheelbase this year is 115 inches; tread standard; spring suspension is as before, which includes three-quarter elliptic springs of the scroll type, and ball or roller bearings are used at every point. The tires are 34 by 3 1-2 inches on all wheels, and the road performance, despite the excellent qualities of the car is on a distinctly improved basis.

Fan driving methods are various, but in clean lines and direct attack of the main problem, no one of the solutions excels that of Paul Gaeth, designer of the Gaeth cars. As the appended illustration shows, the forward extension of the crankcase has a slot through which a wide-faced, flat leather belt passes, connecting the driving pulley on the crankshaft extension and the fanshaft above with a continuous source of power. The case is not left open, but the lower part, below the driving pulley, is closed in completely so that no road dust or dirt may penetrate through openings there to the more delicate crankshaft parts within. The fan itself has four blades of approved shape, and is carried on a shaft extended from the front cylinder, and bolted to a projection thereon. The bolting up arrangement is such as to allow a rather extensive adjustment motion, so that no matter how much the belt may stretch, the adjustment is sufficient to care for it and maintain the necessary tightness. Other features of this car may not be seen in this view, but the thermo-siphon cooling system is very well worked out, the water pipes being unusually large in diameter.



CORBIN MODEL XVIII SELLS FOR $2,750

The motor in this car has four cylinders, works four-cycle, the bore is 4 1-2 inches and the stroke is 4 1-4 inches. The cylinders are cast individually, and a gear pump circulates the water from the jackets through a honeycomb type of radiator, it being designed for the right capacity and so made as to operate noiselessly. The Bosch ignition system is supplemented by a dry battery, and lubrication is positive through the good office of a pump. The cone clutch is of the latest and most approved design, serves in conjunction with a selective three-speed gear, and the shafl drive to a live rear axle is substantially straight lined. The chassis frame is strong, designed to work without perceptible deflection, notwithstanding the 120-inch wheelbase, which indicates a somewhat lengthened span. Ball bearings are used in the transmission and axle, and hand-hole plates are large and quick detachable, thus giving access to the crankcase, transmission gears, etc., so that on the road, should it be necessary to make a quick inspection, it is the easiest thing in the world to do. The schedule weight of this car is 2,780 pounds, and the load is carried by 34 by 4-inch tires front and rear.

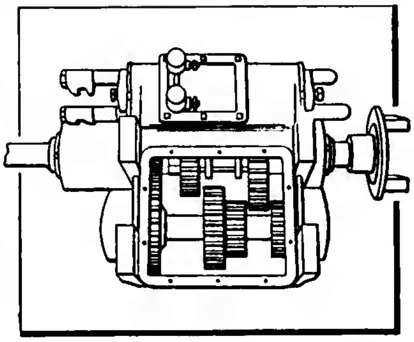


Simplicity is what we are all striving to attain, accomplishing this with as little loss as possible. In the Elmore cars this is sought for by the use of a two-cycle engine, a cross section of which is herewith illustrated. In this form of engine there are no valves, and the moving parts are thus reduced to a very few, and those of an indispensable character. The three port type of engine is used, the mixture being drawn into the crankcase, there compressed to several pounds pressure above that of the atmosphere, drawn into the cylinder from there by means of a by-pass or third port. In the cylinder, the operation of compression, explosion, expansion, and exhaust are completed in two strokes, that is, one revolution. This latter makes for a continuous and even torque, the power impulse occurring on every down stroke. To say the least, this is easy on the driving members, clear through the road wheels and their covering, the delicate pneumatic tires. One result should be lessened upkeep costs, which are interesting to every owner and prospective owner. This is a matter which cannot be given too much publicity or discussion, since every man converted converts others, the whole redounding to the good of the industry.

DEMOT CAR AS IT IS BRIEFLY DESCRIBED

Taking the most recent information to be had directly from the maker, through the Demot Car Sales Company, Detroit, Mich., the car, which is one of the newcomers of the year, is composed as follows: Roadster body on a chassis frame, of the channel section, has a seat for two, placed a little towards the rear axle rather than in the mid-position. The power plant has a motor which is rated at 10 1-2 horsepower, and is of the double cylinder type, with bore and stroke of 3 5-8 hy 3 1-2 in. respectively. The motor is of the 4-cycle, water-cooled type and a vertical tube radiator is used in the cooling process. Ignition is by Remy magneto, with an auxiliary system comprising a coil and dry cells of battery for the electrical energy. Luhrication is by splash, and a disc clutch connects the motor with the driven members. From the clutch to the road wheels is through a planetary gear system which gives two speeds ahead and reverse. The propeller shaft which connects the planetary gear with the live rear axle is provided with two universal joints, and the gear ratio is that which seems to best serve in view of the use of 30-in. diameter of pneumatics; they are 2 1-2 in. section—same in front as rear. The car is said to weigh 800 pounds and anti-friction bearings are generously used; this includes annular ball bearings for the crankshaft. New-Departure bearings in the transmission, and plain bearings in the journals of secondary importance, although worthy of brief mention. This size is ample in view of the work to be done, particularly when it is considered that the car is not essentially for racing work.

On the newest Apperson, the drive is by shaft, instead of chains, which are much affected by this company, and, in fact, are still used on a number of models. In the cut the transmission of one of the shaft-driven models is shown. Except on one model, three speeds are furnished. The gears are of wide face, and slide on large sized and stiff shafts of high-grade material. At the right can be seen the universal joint, while at the left is just a glimpse of the square driving shaft.



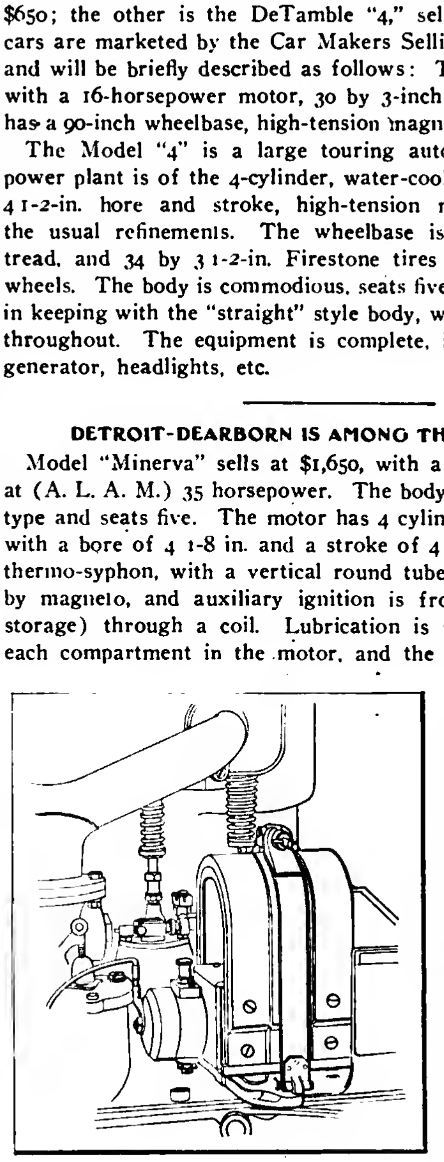
DETAMBLE CARS AS EXHIBITED AT DETROIT

This make of automobile is represented by two models, one of which is a roadster known as the DeTamble "2" and sells for $650; the other is the DeTamble "4," selling at $1,400. These cars are marketed by the Car Makers Selling Company, Chicago, and will be briefly described as follows: The Model "2" is fitted with a 16-horsepower motor, 30 by 3-inch Hartford pneumatics, has a 90-inch wheelbase, high-tension magneto, and a rumhle seat.

The Model "4" is a large touring automobile, in which the power plant is of the 4-cylinder, water-cooled type, with 4 1-2 by 4 1-2-in. hore and stroke, high-tension magneto ignition, and the usual refinements. The wheelbase is 115 inches, standard tread, and 34 by 3 1-2-in. Firestone tires are used on all four wheels. The body is commodious, seats five, and the upholstery is in keeping with the "straight" style body, with No. 1 m. b. leather throughout. The equipment is complete, including an acetylene generator, headlights, etc.

DETROIT-DEARBORN IS AMONG THE DEBUTANTES

Model "Minerva" sells at $1,650, with a motor which is rated at (A. L. A. M.) 35 horsepower. The body is of the new torpedo type and seats five. The motor has 4 cylinders, T-head, in pairs, with a bore of 4 1-8 in. and a stroke of 4 3-8 in. Cooling is by thermo-syphon, with a vertical round tube radiator. Ignition is by magneto, and auxiliary ignition is from a battery (dry or storage) through a coil. Lubrication is positive, two feeds to each compartment in the motor, and the clutch is a shoe type,



While any discussion of the subject of low versus high tension ignition would be foreign to these columns, it will serve the purpose well to call the attention to small, but well worked out ignition details, whether pertaining to the one or the other. Thus the cut shows the low tension magneto of the Locomobile, and the method of fastening it in place. This is by means of a flexible strap passing over the top of the magnets and jointed at the top. As it is hinged at the bottom of the side, opening the joint at the top allows of throwing the whole thing off to the two opposite sides.

internal expanding. The transmission gear is of the sliding type, selective, three speeds ahead and reverse, located under the toe-board, just back of the clutch. The wheelbase is 112 in., tread is 56 in., and the side bars of the frame are of the channel section with a double drop. The live rear axle is of the type using ball bearings, is stout but not heavy, and in the transmission system Timken roller bearings take the load. The weight of the car is said to be 2,200 pounds, and the tires used are 36 by 3 1-2 in. pneumatics on front as well as on rear wheels, that is, the same all around.

A—Shows a row of core boxes and the cores for Rambler individual cylinders, one of which is being placed by a molder. Cylinder casting is an art all by itself, and the work has developed to such an extent that molders taking up this work specialize in it to the exclusion of all other forms of molding. Frequently cylinders are molded on end, but in this particular case they are molded on the side and poured end up.

B—Finished crankshaft of a Simplex automobile which was made from a slab of chrome nickel steel and thereafter fashioned by machining processes, the final finish being by grinding on a special tool devised for the purpose.

C—In the Rambler plant, presenting a row of aluminum housings, showing steel tubes passing out from the housing extensions, which is the way the product looks after it comes from the foundry, as shown in C.

D—Heat treating furnaces as used in the Jackson plant, showing a pyrometer on a wooden stand between the two furnaces. This class of equipment is available for the many purposes which, in conjunction with a forge, permits the accentuation of kinetic qualities in materials as used in Jackson automobiles.

E—Is a view of the Rambler foundry, showing the teeming of aluminum into the mould in the process of casting the aluminum housing for the gears and the steel tube into place, one of which in the finished state is presented in the background.

F—A bulldozer used for cold pressing cross bars and other work in connection with chassis frames, showing in this particular case how tubing is bent in dies.

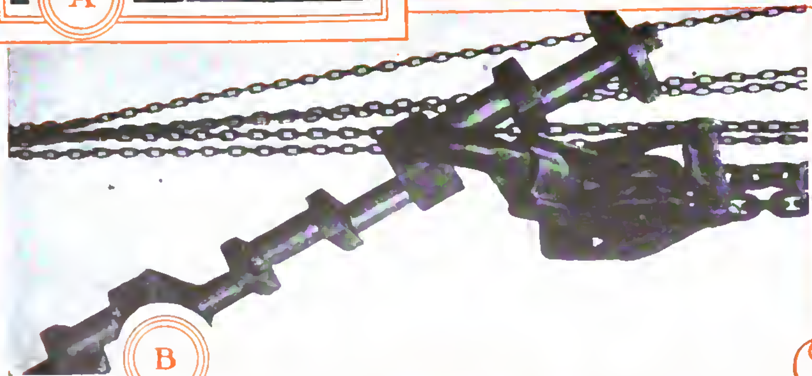
PLATE II.

IN THE FORGE AND FOUNDRY

A

C



B

D

DORRIS "E" IS THE EXPRESSION OF 1910 IDEA

This car which is known as Model E, has a motor with valves in the head, which has long been a Dorris idea, and the Atwater-Kent ignition system is employed with a view to economical and efficient work. The company also equips with a Bosch dual ignition system as an extra. The exhaust manifold and piping in Dorris motors are so nicely designed that excess intake depression, as well as exhaust back pressure, are done away with, thus increasing the power and

G—Large press in the Diamond chain plant blanking out links for sprocket chains as used on trucks, which branch of the chain making business has increased wonderfully of late, due to the renewed and greatly increased interest now manifested in the power vehicles. Nearly every manufacturer in the land is doing something in this line, and Diamond is representative of advanced practice.

H—Finished crankshaft for an Excelsior motor which originated in a drop forging, using special steel and modern methods.

I—In the National plant, presenting a quantity of aluminum castings as they come from the foundry of the character as used in the lower half of National automobiles.

J—Is a core which is used in moulding the upper half of a Rambler crankcase. The molder is slicking up the core preparatory to the baking operation, which is done in a special oven called a core oven. In this the core is baked as hard as a board, in which condition it is ready to go into the mold. Nowadays core making is as much of an art as is the molding itself and requires fully as much skill, else the whole result will be a larger percentage of wasters, the bane of every good foundry.

K—One hundred ton press making side bars in the A. O. Smith plant. The use of pressed steel has advanced apace in the past five years, until now it is used for nearly every piece of the automobile, even for crankshafts and crankcases. To make this possible it was necessary for some far-sighted manufacturer to install an unusual press equipment just like the one here illustrated.

L—How bar stock is stored in the plant of the Diamond Chain, each section being for a particular grade of steel and suitably marked for the purpose of identification.

K

L

I

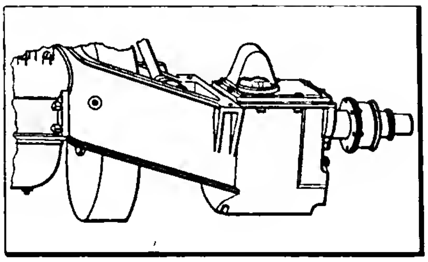
J

H

flexibility of the motor. A Stromberg carbureter operates in its customary efficient way, and has been found by the Dorris Company to co-operate with the motor, delivering a certain uniformity of mixture, which lends facility to the speed

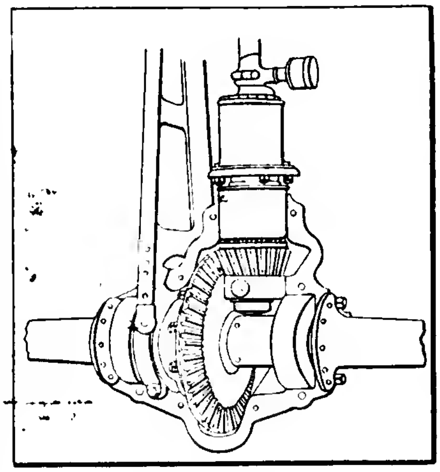


Unit construction has advanced much in the past few years, and the cut shows a sample—and a good one, too—of the unit form of power plant, as used on Moline cars. This has the advantage of reducing the whole chassis to a very small number of parts, the engine and transmission being removable as a whole.

changing process, thus, in some measure, accounting for the flexibility for which the Dorris car is noted. The propeller shaft on the Dorris has a universal slip-joint construction, which will be well worth examining. Nickel steel, in the machinery equipment, makes it possible to design for desired lightness.

THE ELMORE HAS NO VALVES AT ALL

There are two Elmore models, one of which is known as the 36 and the other as the 46. The first sells for $1,750 and the latter for $2,500. Both are touring cars, seat five, have four-cylinder motors, the bore and stroke being the same in both cases, *i. e.*, 4 1-2 by 4 inches. To some further extent the two models are on a common basis, but a change may be noted when the wheelbase is considered, it being 110 inches in Model 36 and 10 inches longer in Model 46. The weight of the Model 36 is 2,400 pounds, and the remaining model weighs 400 pounds more. On the lighter model the tires are 34 by 4 inches all around, but to carry the heavier weight of the big car the tires are 36 by 4 inches all around. The scheme of the motor is shown by illustration elsewhere, in which it will be observed that there are three ports which are uncovered in the right succession, thus eliminating the noise and uncertainty of an automatic crankcase valve,

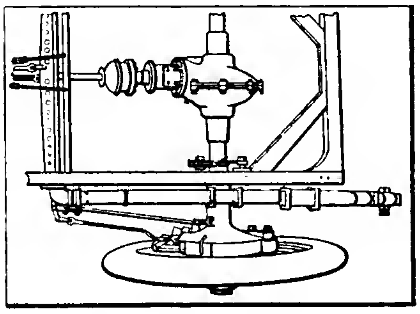


In the construction of the rear axle, proper provision must be made for the thrust of the bevel gears, and the torque reaction of the motor. In the Royal tourist car, both of these are adequately cared for. Ball thrust bearings take the thrust from both levels, back of which are located the radial bearings. To take the torque of the engine, a triangular form has been used, the material being pressed steel, and the shape, that of a channel, with the open side to the right. This channel shape continues throughout the entire length although tapering down to a small vertical height.

which, according to the Elmore staff, is likely to be noisy and may get out of order. In all other respects the Elmore motor furnishes all the earmarks of excellence in mechanical design and construction, while the materials employed are said to be selected with care in view of the work which experience has identified.

FAL CAR, A NEW ONE, IS MADE IN CHICAGO

Sells at $1,650, has an A. L. A. M. rating of 28.9 horsepower. s built for touring; the motor is 4 1-4 x 4 1-4 inches bore and stroke, cylinders are cast in pairs, and a tubular radiator serves for cooling. Ignition is by magneto and battery, with positive lubrication through the good office of a pump, and a cone clutch in connection with a three-speed selective transmission gear, is responsible for speed changes beyond the range of flexibility

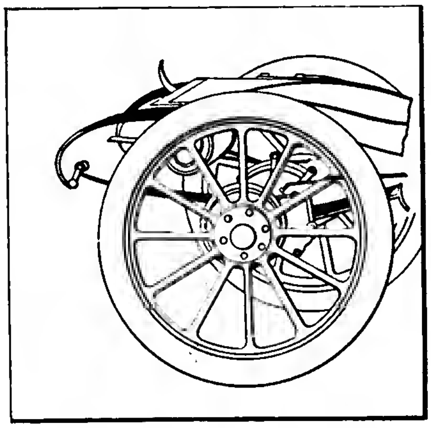


Knox Model R chassis, at the rear end as it appears from above. The equality in the pull at the two brakes is produced by the use of the flat equalizing bars shown here. These are very long, and extend through the side members of the frame, which act as guides for the bars. At the rear end, the frame is strengthened by the diagonal inset piece, this being of the same shape as the frame.

of the motor. The wheelbase is 110 inches, and the weight of the car is given as 1,900 pounds so that the 34 x 3 1-2-inch pneumatics are equal to every need. A detail of the torsion tube is given as the illustration accompanying this statement, and attention is called to the excellence of detail of the live rear axle, brakes, and methods of control, in which it is true that the brake system is inside of the line of the springs, and the part of the axle which carries the perch on each side, has arms extended, spider fashion, with bearings integral therewith to support the brake arms, and lend facility to the process.

FORD PROMINENT AMONG IMPORTANT CARS

Among the makers of touring cars no one is better known than Henry Ford, while the same might be said of his product. This little car, differing now in very few details as originally brought out in 1906, is a four-cylinder, water-cooled, four-cycle machine with bore of 3 3-4 inches and 4-inch stroke. The maker's rating is but 20 horsepower, while the usual formula would allow a rating of 22.5. Although formerly strictly a runabout, pressure from the buying public has forced the use of a touring body accommodating four. The wheelbase of 100 inches is ample, the tread is standard, engine cooling is by thermo-siphon, lubrication

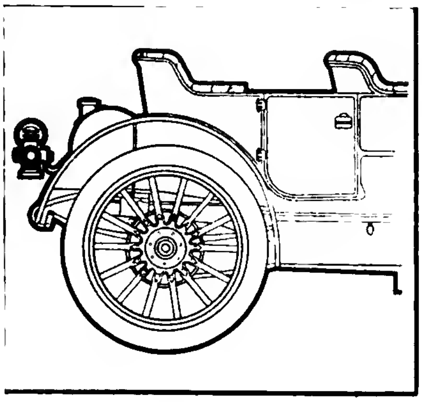


Among the newcomers, Hudson cars show many little points which savor of old experienced factory heads. Thus, the rear construction of the Hudson "Twenty" shows a decided upsweep in the frame, three-quarter, scroll ended, elliptic springs, a muffler set across the frame to look like a pressure gasoline tank, such as is used on cars of ten times the price. For the size, power, and weight of this runabout, the wheels and tires are of large, not to say ample, diameter. Rear wheels have twelve spokes.

is by splash, and other details are up to the standard of excellence of the big new Highland Park factory, just occupied. Any mention of this car would be incomplete without a terse statement of the use of vanadium steel, the anti-fatigue metal, which is used liberally throughout the chassis.

AIR-COOLING NOW AS EVER FRANKLIN'S STANDARD

With a consistency rare these days, the makers of the Franklin automobiles hold strictly to air cooling and light weight construction. Three models are made, differing in power, length of wheelbase and body styles. These are lettered G, D and H. The first is an 18.2-horsepower car, with engine of four cylinders, 3 3-8-inch bore by 4-inch stroke. The wheelbase is 91 1-2 inches, tread is 53 1-2 inches, tires are 32 by 3 1-2 inches front

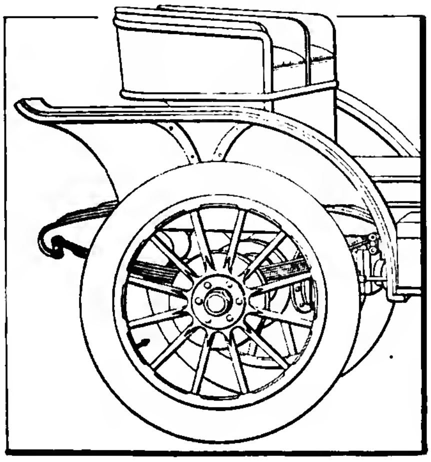


The sides of this body look low, but they are not. The low impression is conveyed by the comparison with the wheels, which comparison is deceptive for these are forty-two-inch wheels, and the car, the Oldsmobile Limited. The large diameter wheels swallow up small road inequalities much more readily than would those of smaller size, making the car as a whole ride much easier. This is one of the features of the big Oldsmobile which is being advocated widely as advanced automobile construction.

and 32 by 4 rear. In the next larger model, D, called 28.9 horsepower, with a 4 1-4-inch bore and short stroke of 4 inches, the wheelbase is increased to 106 inches with touring body and 114 1-2 inches with enclosed bodies. Tread remains the same, but larger wheels and tires are used, 36 by 4 front and 36 by 4 1-2 rear being the exact figures. Model H is the only six, and the biggest and best of the line. The engine is of 4 1-4-inch bore and 4-inch stroke, rated at 43.8 horsepower. A wheelbase of 127 inches and typical Franklin springing makes riding easy, while the large tires, 36 by 4 1-2 and 37 by 5, make maintenance expense low.

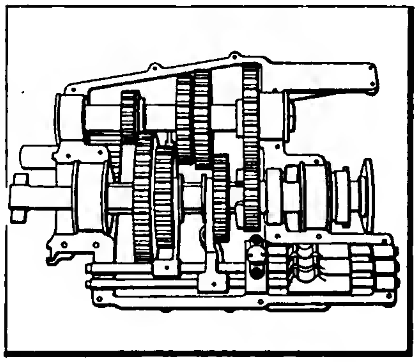
GAETH AUTOMOBILE MOTOR IS EXTREMELY SIMPLE

In this motor, as it is applied to Gaeth automobiles, the upper half of the crankcase, instead of having individual arms reaching out to the chassis frame, is so flanged that all the space between the face proper and the frame is engaged, with the result that the under pans or sod aprons, as they are sometimes called,



Black-Crow is the name of this newcomer from the West and showing a full line at the Chicago Show. The small view illustrates the rear end of the Model D roadster body. This shows two rumble seats, but also comes with but one, or without any if desired. In combination with the low, comfortable seats in the back, the very high fender adds to the comfort of the occupants by shielding them from the mud of the road. The leg room between the rear seat and the back of the front framing is ample. Just a glimpse may be had of the rear end of the large and roomy tool box.

do not have to be used. The magneto is placed on the left side of the motor, and is protected by the case flanging, so that it is not only accessible and directly attached (without driving through a pump), but lost motion and other possible troubles are eliminated. The exhaust manifold is especially designed for reducing back pressure to a nominal value, and as the exhaust sweeps out of the transfer ports the shape of the manifold is such that it is swept upward and then away by easy curves, and the working space around the motor is increased by this shape as well. The water piping on top of the twin cylinders is especially well designed, and it tapers from the small diameter at the rear cylinder to a sufficiently large diameter for the front cylinder to compensate for the differences in volume of water, and the distribution is, therefore, on a satisfactory basis. It is very likely that the Gaeth make-and-break system of ignition is more inter-

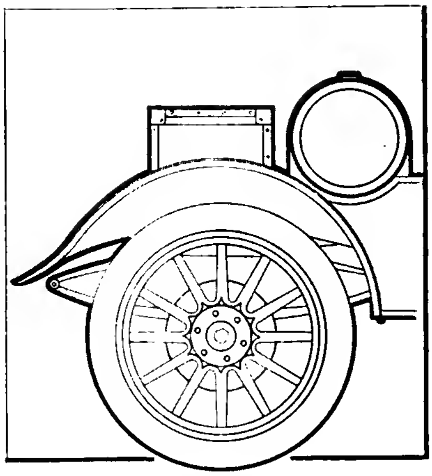


Four speeds forward and one reverse are provided in the Stearns gear box. The gears and shafts are made from chrome-nickel steel, which is the strongest and toughest material available. Annular ball bearings are used throughout. The gears are shown in the high speed position, this being effected with a series of jaws on the forward end of the one gear, which mesh with a similar series of jaws cut into the main driving gear.

esting than some of the other points which might be mentioned, but this system has been quite fully described heretofore, and space is here too limited to indicate a repetition. The motor has four cylinders with a bore of 4 7-8 inches and a stroke of 5 1-4 inches, which brings it into the long-stroke type. The A. L. A. M. rating is 38 horsepower, and with a touring body the car sells for $3,500.

THE HUDSON "TWENTY" IS MAKING HISTORY

The price of this car is $1,000, and the A. L. A. M. rating of the motor is 22.5 horsepower, with a four-cylinder, water-cooled motor, a bore of 3 3-4 inches and a stroke of 4 1-2 inches; cylinders cast *en bloc*. Cooling is with a tubular radiator of the McCord type, and a centrifugal pump circulates the water advantageously. Ignition is with a dry battery and coil, excepting that a magneto may be had as an extra. The wheelbase is 100 inches, with a 56-inch tread in the roadster type, but the same car when put out as touring type has a wheelbase of 110 inches. The chassis frame is pressed steel of nice design, and plain bear-



In place of the usual single rumble seat, the Oakland Model M, forty-horsepower car has a very large gasoline tank and a big, broad trunk. The seating capacity is, of course, but two, still the added convenience given by the increased mileage per tank full of gasoline, and those due to the capacity of the trunk more than make up for this. The tank is held in place by several wide metal straps, and has a very large central and accessible filling cap. Fenders are wide and deep, to afford maximum protection, while the seats are low and comfortable. The long fenders give the impression of speed.

ings are used in the crankshaft and other places, excepting for the axles. The cylinders are cast from a special grade of gray iron, and ample means is offered for the escape of gas in the foundry process. The crankcase is supported by four sturdy arms and the crankshaft is of a special grade of crankshaft steel in which the tensile strength is minimum at 100,000 pounds per square inch, and the elastic limit holds to a high point, due to proper heat treating, which is done under well-defined conditions. Accuracy is due to grinding as the final operation, and the methods in vogue in the shop are all with a view to producing a car which will be suitable for all around and strenuous road work.

A—Represents a vertical turret boring mill finishing the cone face of a flywheel as used on National motors. This method of finishing flywheels is quick, accurate, and has the further virtue of making them interchangeable. It is something of an advantage to be able to assure purchasers that a flywheel will not have to be sent out if, for some cause, it is necessary to replace a crankshaft, and this will be a condition when the flywheel work is done on a machine which eliminates the personal equation.

B—Is a small Bullard (vertical) mill with a turret attachment, which is the latest substitute for a lathe as used in the process of machining flywheels for automobile motors. This view was taken in the Excelsior plant.

C—Represents a horizontal boring mill finishing a housing for use in a National transmission system. When special fixtures are properly made it is quite an easy matter to take the fullest advantage of lathes, it being a well recognized fact that this character of tool is very nimble, delivers good accuracy and lends facility to the process in view of the skill of the men who have to do the work.

D—Represents a special cutting off tool photographed in the Rambler plant, showing the method of parting piston rings from the turned up casting after it was machined to the correct bore and outside diameter.

E—In the Rambler, showing a special fixture for holding individual T-head cylinders and method of rough machining in a lathe rigged up for this specific purpose.

F—A vertical mill with a turret head finishing bevel gear blanks as used in the bevel drive on Rambler automobiles. In the making of bevel gears it is something of an undertaking to do the work of blanking, then machining, and considering the use of alloy steel, accomplish the operations quickly, keeping cost low.

G—In the Moon plant, showing a turret lathe fitted with a face plate and a suitably shaped mandrel over which a piston is pressed, and the grooves for the piston rings are being finished.

H—Making Diamond chains—a battery of automatic screw - making machines turning out alloy steel rivets.

I—In the Excelsior plant a multiple cutter lathe finishing cam shafts with a cutter working between each pair of cams. A cutter for each round portion, working in unison with the other similar cutters, is like subtracting a man from the payroll for each additional cutter in actual use on a given tool.

J—Acme four-spindle automatic tool, working on small concentric round parts as used on Excelsior motors in which a single workman takes care of a battery.

K—No. 4½ Bardons & Oliver turret lathe in the Excelsior plant, on semi-automatic work, depicting the rapid and accurate production of small concentric round parts as used in Excelsior motors.

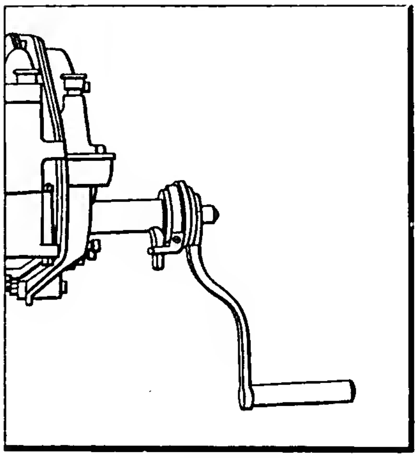
L—Turret lathe in the Excelsior plant finishing gear blanks at high speed on a double setting. The work which is being done is a fine illustration of the value of turret lathes when they are properly fitted out with special fixtures in view of the shape and character of the parts to be machined, and it is hardly to be supposed that any other generic type of machine tool would lend better to the undertaking.

M—Hollow spindle automatic machine tool drilling out concentric round parts and cutting off as exemplified in the Rambler plant.

N—In the Rambler plant, making helical springs, utilizing a small special tool which has substantially the characteristics of a lathe, the reel of wire showing in the foreground.

O—Jones & Lamson turret lathe in the Excelsior plant, working on gear blanks.

P—Heavy turret lathe in the Pierce-Arrow plant, machining the brake spider and sleeve as used in Pierce-Arrow live rear axles. This is a very interesting example of the use of a machine tool with a hollow spindle, in which the round bar is placed and shoved forward as the parts to be made are finished. In this way the feed is as rapid as the occasion demands, and the time which is usually taken in setting up the work is avoided. As a rule mistakes are most likely to happen during the setting up operation, and it is in this process that the most time is consumed.



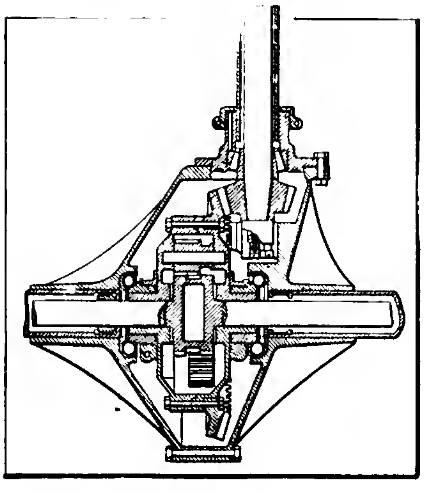
Alco is showing a starting crank which prevents back kicks and troubles of this sort are eliminated beyond any doubt. The method, as shown, is so compact as not to alter the front appearance of the car, and, by a reverse motion, which is housed in, the finger which is the only part which extends out from the housing, intercepts a dog on the crank, by means of which the reverse motion is thrown into gear and the crank is thereby disengaged within about a quarter of a revolution of the crank. The device is so simple that to get out of order is quite out of the question.

MORE POWERFUL INTER-STATE LOOKS GOOD

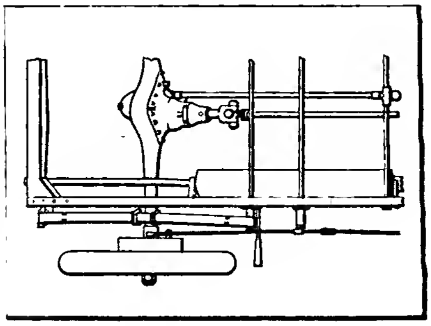
Among the new cars, no one looms up better than does the Inter-State "Forty," which is made in three models, designated as 30, 31 and 32. These are but the methods of indicating the differing body styles, for all three rest upon the same chassis. Thirty refers to the touring car body with standard equipment, ready for five large people, and with plenty of leg room. Passing on to Model 31, it is the demi-tonneau or short coupled body as some prefer to call it. In this the rear seat is just above the rear axle, and although the capacity is reduced to four persons, the feeling of roominess is unchanged. Model 32 is the runabout, the same designation applying whether no rumble, single, or double rumble is used. The chassis is powered with a motor of four vertical cylinders, of 4 1-2-in. bore and 5-in. stroke. It is rated at 40 horsepower by the makers. All engines' parts are finished by the grinding process. The wheelbase is 118 in. and the tread standard. All wheels are made interchangeable by the use of the same sized tires all around, 34 by 4 in. In touring form the weight is given as 2,700 pounds, which is reduced 50 pounds by the use of the smaller capacity bodies. Among the parts or qualities featured by the makers are: Transmission and disc clutch in a unit; two distinct ignition systems; very efficient lubrication; unusually large steering wheel; well selected springs, making riding easy, and very complete equipment without extra charge.

THE JACKSON LINE INCLUDES THREE MODELS

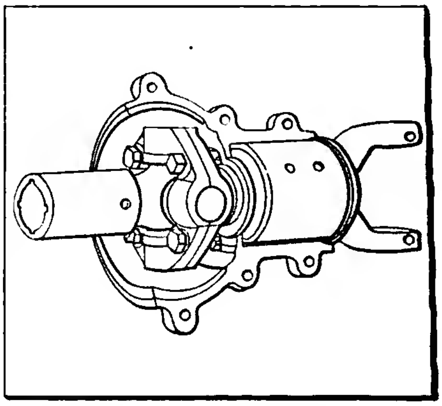
Perhaps the most conspicuous new idea in the Jackson line of cars will be found in the method of transmitting the power from the crankshaft to the superimposed camshaft on the 30 model. The next point of unusual merit, which will he found in all Jackson models, lies in the method employed in housing the walking beams which actuate the valves in the head in response to the lifts as they reciprocate under control of the cams. The walking beams, and, in fact, all moving parts are housed in, accessible by means of covers, and the bearings swim in oil, which is replenished continuously in response to the demand. The valves are set at such an angle that the gas, due to combustion, has a direct passage as it whisks away to the muffler, and back pressure is reduced to a mere suspicion because of this fact, which is furthered by the proper use of a well-designed muffler. In the Jackson models, excepting the 30, a plate clutch is used, there being three discs under control of a toggle system and means of adjustment renders it a simple task to take up for such wear as there may be in time. Jackson cars are swung on full elliptic springs fore and aft, and the springs are so designed that the mass of material is in sufficient presence, considering the energy which must be absorbed to snub the vertical bounce as it is induced by the speed of the car as it negotiates road inequalities. In the Jackson plant, as is generally well understood, the equipment includes everything from drop forgings to the finished article: even the springs are made in a nearby shop which owes its allegiance to the same deity.



Rambler live rear axles, in view of the service they render, are worthy of reproduction in section in order to help purchasers to understand how they are assembled. The differential gears and pinions are especially well made, and roll on ball bearings which are placed at the ends of the shells. The bevel gear is integral with one-half of the differential housing, and the meshing pinion is supported at the end of the torsion tube hy means of a tapered roller bearing which is of the Rambler make. The same pinion is supported at its outer end by a plain bearing, which is sectioned.



Timken roller-bearing axle as used in a considerable number of automobiles which will be at the show. This axle has a special-shaped drawn - steel shell, which houses in the differential gear, bevel drive, and shafts. The differential gear system, as well as the bevel drive, are in a separate unit which may be removed from the steel shell for inspection or repair, and in reassembling, trouble is eliminated.



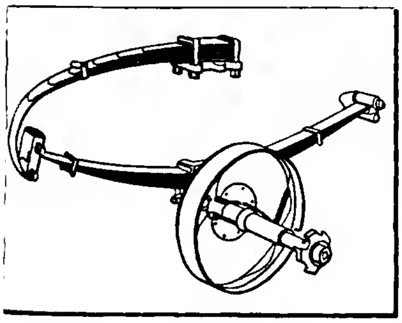
In the Regal automobiles, while there are many points of mechanical merit to be examined closely, it is the purpose here to call attention to the universal joint at the motor end of the propeller shaft, and also to the presence of a nickel steel Hyatt roller bearing of extra proportions to take the work. This bearing is supported by a crossbar of rigid design, and the machinery is thus relieved of any of the shock which comes from the road in contact with the wheels. This plan adds to the transmission stability.

KNOX R CHASSIS IS A MECHANICAL MASTERPIECE

The Model R chassis has a 40-horsepower motor, and is built for touring, with a body which accommodates five comfortably. The cylinders are 5 by 4 3-4 bore and stroke, respectively, of which there are four, cast separately, with valves in the head, and a silent rocker system by means of which they are actuated through the good office of a single camshaft which resides in the crankcase below. In order to get at the valves quickly for any purpose, the head is made separable and may be unbolted by a novice with small effort. The transmission gear is in an extension of the crankcase which forms around, leaving a rectangular space in which the flywheel spins, with room enough besides for the clutch, pedals and relating parts. The cellular radiator is sufficiently large for the purpose, and proper cooling is further assured through the suitable use of a centrifugal pump. A Bosch high-tension magneto furnishes ignition on a high plane, but for purposes of cranking and in an emergency a coil and storage battery are employed. Lubrication is positive through the use of a pump, and the clutch, which is a three-plate system of the dry type, co-operates with the selective three-speed transmission gear and shaft drive to a live rear axle of undoubted quality, utilizing a pair of universal joints, one at either end of the propeller shaft. The wheelbase of the car is 117 inches, and standard tread, with a well-shaped special steel channel section set of side bars, reinforced at the narrowing point on which the body rests.

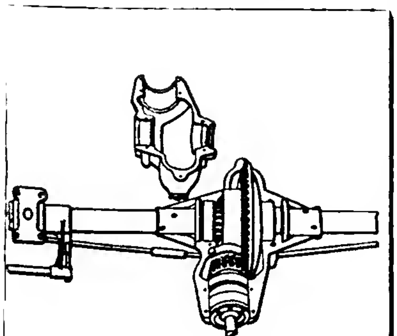
KRIT IS A NEW MODEL FROM AN OLD DESIGNER

Model A of this make came out this year and is built by the Krit Motor Car Company, Detroit. The price is $800 and the body is a runabout type seating two. The power plant comprises a 4-cylinder, 4-cycle, water-cooled motor, with cylinders 3 3-4 by 4 inches bore and stroke, respectively. The cylinders are cast



In the Chalmers-Detroit 30 there is probably no point which attracts more attention than the easy-riding qualities of the car, and in looking for the reason it is probably necessary to examine the rear spring suspension. The springs are 3-4 elliptic (scroll), with wide plates, and so designed that the period of the oscillations is properly regulated. The fastening at the chassis frame is well made.

en bloc, and a tubular radiator is connected for thermo-syphon work so that the water is circulated without the use of a pump. Ignititon is by a magneto, which is included in the selling price;



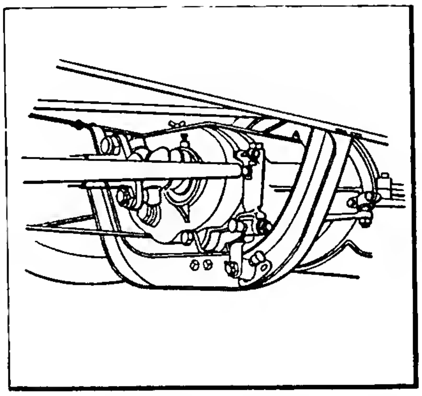
In the Corbin Full Jewel it is believed that the live rear axle is well worth the attention of the discriminating buyer, and for the purpose of reflecting something of what will be found in the axle this view is offered. The bevel pinion, which meshes with the gear to constitute the bevel drive, is supported most rigidly between bearings, and, in view of the torque which comes on this part, the designer made sure of his ground by spreading the bearings far enough apart to produce the desired result with certainty.

the clutch is multiple disc, and a 2-speed sliding gear system is connected between the motor and the live rear axle. The wheelbase is 96 in. with a 56-in. tread, and 32 by 3-in. tires are used on all road wheels. The weight of the car is given as 1,200 pounds, and ball bearings are placed in road wheels, excepting in the live rear axle, which has roller bearings as well. The crankshaft, however, centers on a pair of annular ball bearings. The side frames are of pressed steel.

LOCOMOBILE MODEL I IS A SHAFT DRIVE AUTOMOBILE

The A. L. A. M. rating of the motor in this model is 32.4 horsepower, and has a four-cylinder motor, 4 1-2 by 4 1-2-inch bore and stroke, with the cylinders cast in pairs. A honeycomb radiator is supported in the cooling effort by a centrifugal pump, and ignition is by low tension with a magneto; the illustration showing the simplicity of the wiring system, method of holding

Stevens-Duryea cars, in view of the unit power plant construction, are enabled to take advantage of the principle of the three-point suspension to the dregs, as it were, and as the illustration shows, the rear end of the power plant case rests at its center on a depressed crossbar of great strength. Considering the fact that this motor is a "six" and that the case must be long enough to accommodate this many cylinders, the designer has seen fit to protect the case from all outside influences.



the magneto in place, and a high degree of mechanical protection. The transmission gear is the selective four-speed system, with a cone clutch, and lubrication is by positive mechanical methods. The wheelbase is 120 inches, and the channel section frame is designed for adequate strength utilizing a fine grade of material, considering the span of supports. Ball bearings are used at all points, excepting in the motor, and the tires on the wheels are 35 by 4 inches front and 34 by 4 1-2 inches for the rear, a rather unusual combination.

In addition to this model the side-chain drive Locomobile of 40-horsepower rating is still in brisk demand, and is put out this year as one of the standard models of the company. The motor in this model is 5 by 6 bore and stroke, respectively; has four cylinders, cast in pairs, and the general construction all along the mechanical line checks up with that which obtains for the shaft-drive model, with the exception that the wheelbase is 123 inches and the tires are 36 by 4 in front and 36 by 5 in the rear, not forgetting, of course, that a side-chain drive is placed in the transmission instead of a shaft.

MATHESON OFFERS 2 MODELS TO DISCRIMINATING BUYERS

Model M is sold at $3,000; is rated at 48.6 horsepower; has a touring body. Model E is sold at $5,000, is rated at 40 horsepower and is rigged out for touring. Referring to Model M, which is a six-cylinder motor, with cylinders cast in pairs, that the rating is conservative is reflected in the bore, which is 4 1-2 inches, and that the company believes in the long-stroke idea, is brought out by the fact that the stroke is 5 inches in this model. Cooling is done by a honeycomb type of radiator, with a centrifugal pump for circulation, and ignition in the main is by means of a Bosch magneto with a battery auxiliary. There are 53 discs in

In Matheson automobiles, while there are very many points to be given serious consideration, the fact remains that the multiple disc clutch as here illustrated is so well designed as to demand more of the purchaser's time than is ordinarily given to a detail or a unit of an automobile. The clutch, as a whole, centers on annular type of ball bearings, and the spring, which is also shown, is so designed as to deliver its quota of work after a fashion spritely. The discs are so made that they seat readily; this is due to the small radial distance across them. The oil, which issued as a lubricant, has but a short distance to travel to get away, and allow seating.

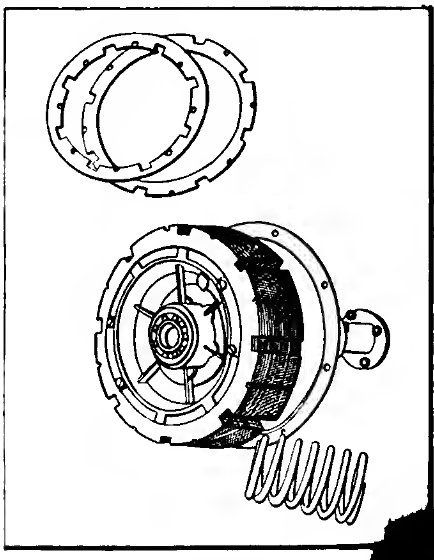


PLATE IV.

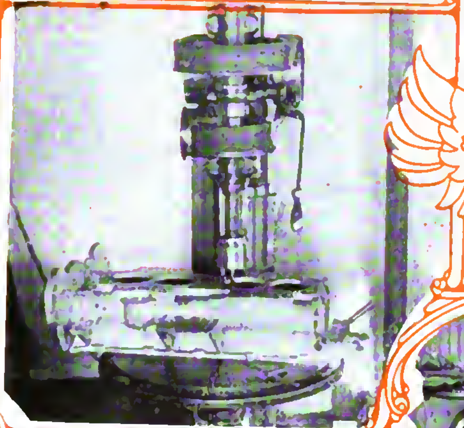
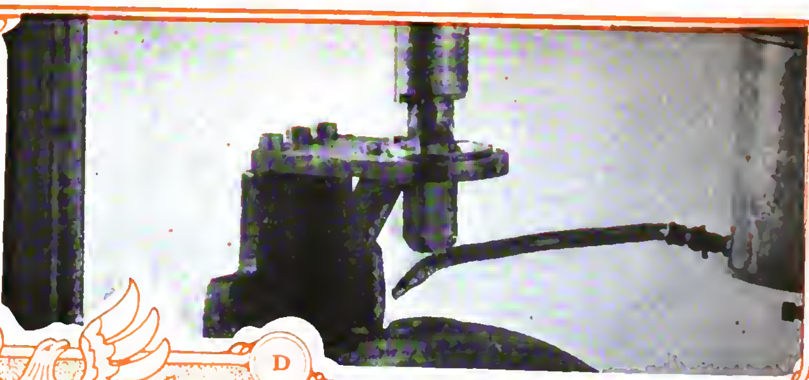
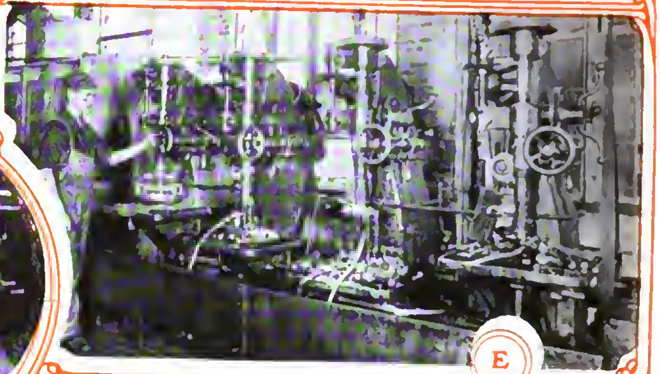
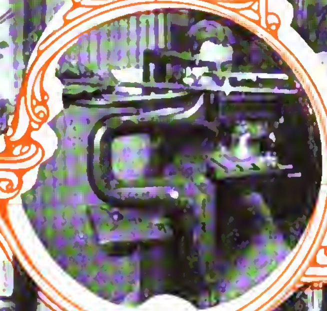
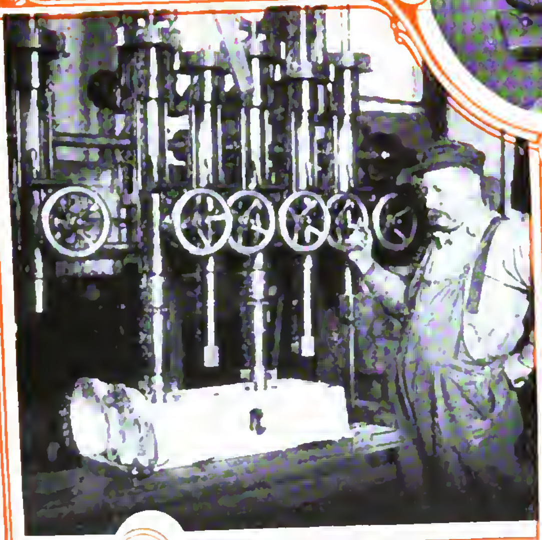
DRILLPRESS APPLICATIONS

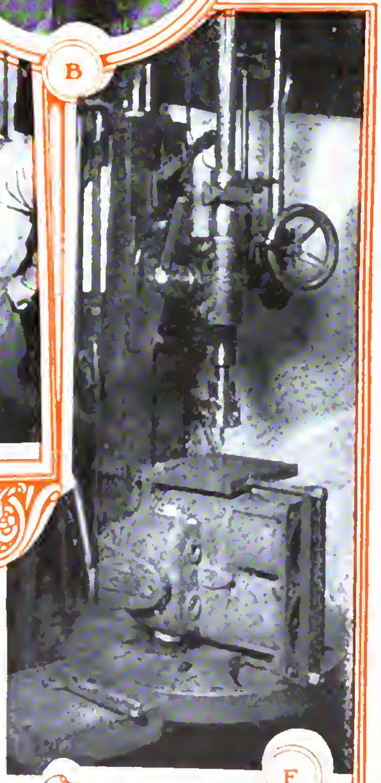


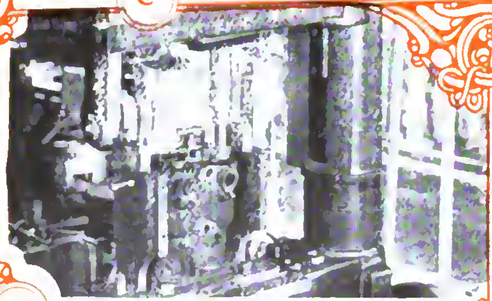


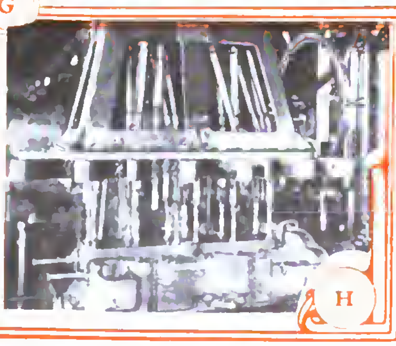












A—Drillpress used in the Moon plant for drilling holes in the aluminum crankcase after they are spotted. This is a small, sensitive drill, whose speed of output is governed only by the operator's ability to hustle. The table swings freely, so that the work is not even bolted down to it.

B—A form of sensitive drill as used in engraving name plates for hub caps on Rambler cars. This tool takes the place of a high-priced engraver. In operation the generating tool is guided by a formed plate which may be seen at the left of the picture, the operator holding the guiding point down to it with his right hand.

C—Multiple spindle drill used in the National plant for finishing crankcases, using wing cutters and reamers as illustrated.

D—Drillpress used in the Marmon plant in connection with a fixture which holds the cover W in line with the tap D which in turn is guided by the hardened bushing B which is bolted through the jig plate G.

E—Battery of drill presses as used in the Rambler plant working on yokes, levers, and other drop forgings under conditions of high speed utilizing special drills.

F—Drill press used in the Premier plant in connection with a special fixture for drilling holes in cylinders, the arrangement being such that the cylinders are automatically centered and the drill is guided through a jig hole with a hardened bushing.

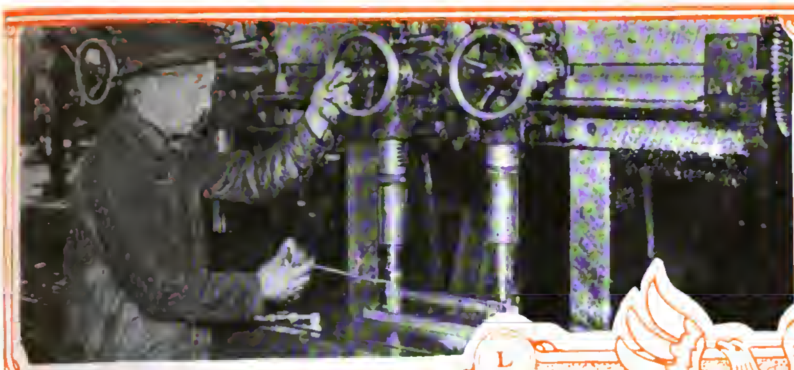
G—Radial drill in the Moon plant finishing valve cover holes in cylinders of the valves in the head type.

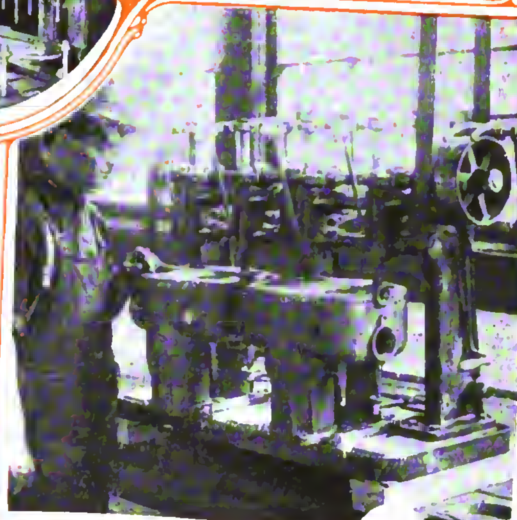
H—Multiple spindle drill working in connection with a jig plate on the upper half of a Premier cylinder, drilling twelve holes at one time with the accuracy which is inherent in the jig, and with speed due to the use of high speed drills kept in excellent condition.

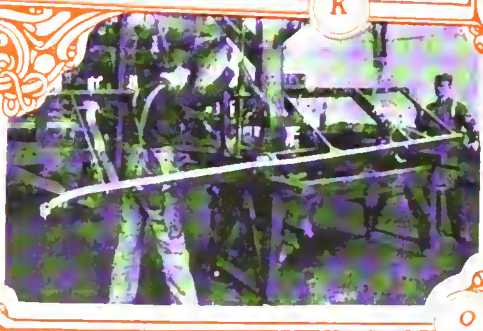
the clutch, and the transmission gear is selective with three speeds and reverse, which connects to the live rear axle by a straight-line drive and a shaft suitably provided for from the point of view of flexibility. The wheelbase of this model is 125 1-2 inches, with a 56 1-2-inch tread. The channel section frames are of special steel of adequate section, showing the earmarks of the designer. The crankshaft rolls on plain bearings, but all other bearings are of the ball type, large for the work and suitably installed. The road wheels have 36 by 4-inch tires all around, which, for the weight of this particular model, are very liberal indeed. A sketch of the multiple disc clutch is given elsewhere in this article, and will prove of more than a little interest to those who follow up the details in design as they relate to automobiles, because the discs are of large diameter, but the distance which the oil has to travel to get away is but slight.

M'INTYRE ADDS AN AUTOMOBILE WITH PNEUMATICS

In addition to the line of high-wheeled cars built by the W. H. McIntyre Company for several years past, this season







I—A special multiple spindle drill used in the Moon plant in cylinder work involving a special fixture. The particular feature of the tool lies in its ability to drill under conditions of close centers as illustrated. This is brought about by gearing the spindles.

J—Multiple spindle drill used in the Excelsior plant in the manufacture of Excelsior motors, working in conjunction with a jig drilling flange holes for a motor end-plate.

K—Special multiple spindle equipment used for grinding valves in cylinders for National motors so contrived that the grinding spindles reverse on a third of a revolution, and the grinding discs lifts off of the valve seat at the dwell point of reversal thus preventing scoring of the valve seats.

L—Multiple spindle drill used in the Excelsior plant in the manufacture of motors, shown in the process of drilling holes in the enlargements of the connecting rod with a special contrived wing cutter which faces off the enlargements simultaneously.

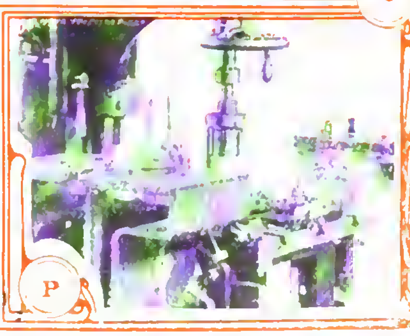
M—Sensitive drills as used in the Diamond chain plant for drilling sidebars and other work in connection with the manufacture of Diamond chains as employed in side chain drives on automobiles.

N—Drill press in the Premier plant rigged up for grinding valve seats of Premier cylinders so arranged that the spindle reverses on a third of a revolution and the grinding disc lifts off of the seat at the dwell point during each reversal.

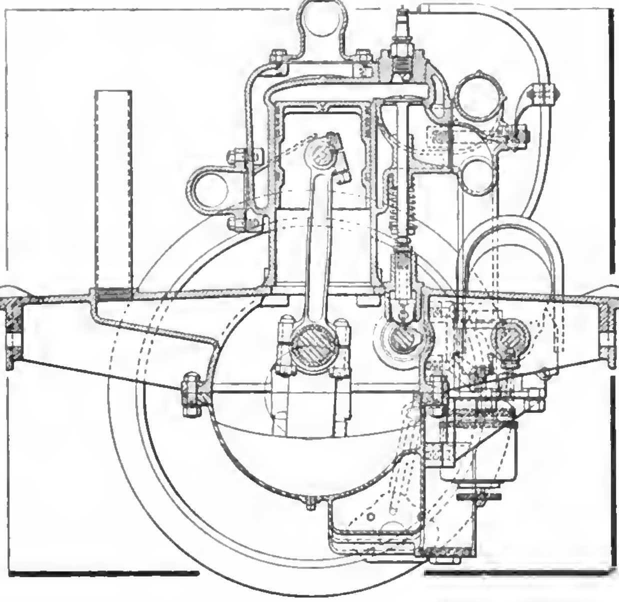
O—Improvised drill in the Premier plant drilling holes in crossbars during process of assembling the chassis frame.

P—Radial drill used in the Marmon plant in connection with a fixture with hardened bushings in the holes showing an end mill T in the socket held in the spindle S. The top portion of the fixture shows the bushings.

will see the production of a machine resembling standard automobiles more closely than does the long-legged critter. This latest addition to the family shows another change, to water cooling, the four-cylinder 4 1-4 by 5 1-2 engine being of this variety. The length of stroke relative to the bore puts this prime mover into the long-stroke class, which produces the power required at comparatively low speeds, this being conducive to long life. The cylinders are cast in pairs, with the T-head form, while the crankshaft is ably supported by long bearings of Parson's white brass. Three body forms conclude the line, a two-passenger runabout, a four-passenger runabout or roadster, and a five-passenger touring car. The former is designated as Model M-10, the second as Model M-15, and the last as M-20. The engine power rating is taken as forty, which at the gear reduction of 4 1-2 to 1 would produce sufficient speed for anyone. Added to long lively springs, a wheelbase of 115 in. makes life worth living in the car, while the tires have the most unusual size of 37 by



5 all around. Considering the weight of the complete car, this tire equipment is one of the most liberal on the market.



Section through National engine, showing the sump for the oil to collect in, and which acts as a source of supply at all times. The dotted lines indicate the pump at the rear end.

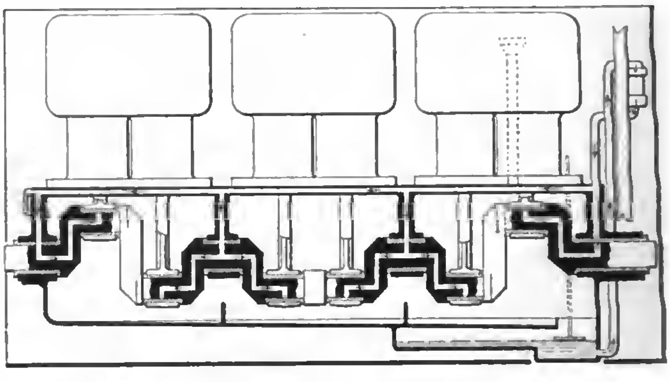
MICHIGAN MODEL D IS A STEAMER COMMERCIAL

Made by the Michigan Steam Motor Company, this model, as it is displayed at the show, may be briefly described as follows:

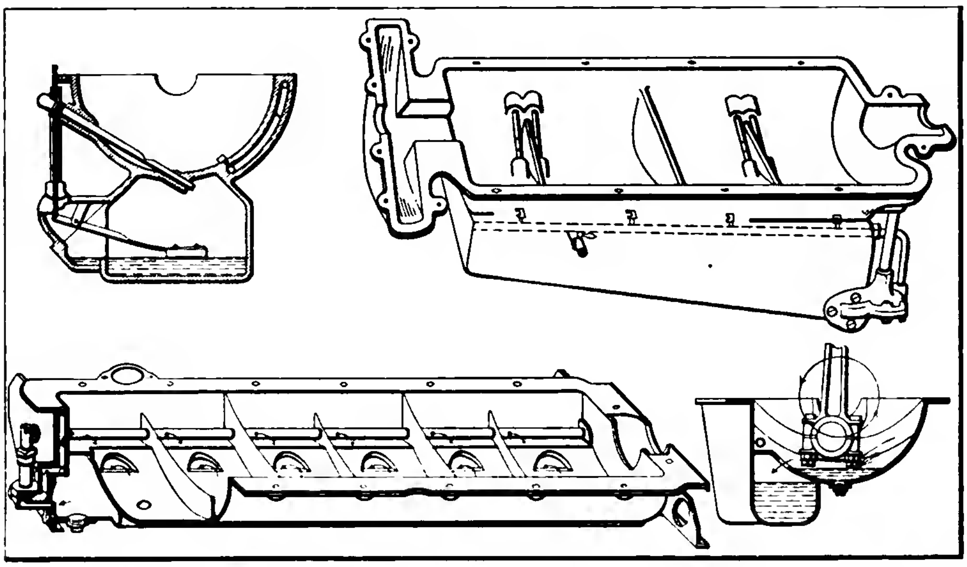
It is a 3-ton truck; body work to order; price $4,000. The power plant has eight cylinders of the type known as twin quadruple compound, with a three-inch stroke. The engine is located under the foot-board, and the steam boiler, which furnishes the energy in acceptable form, is located under the driver's seat. The type of boiler is designated as semi-flash, and a flat tube condenser is used in conjunction with the system. Water is maintained at a constant level, and compactness as well as economy is the aim of the designer. Lubrication is by splash, control is substantially automatic, and one speed change is provided in the transmission gear system. A double side-chain drive transmits power to the rear (traction) wheels, and the wheelbase is 140 in. with a 66-in. tread. The chassis frame is of the channel section, reinforced, and Timken axles are used at front and rear. The weight of the truck is 4,500 pounds, according to specifications, and 4 1-2-in. front tires (solid) are used in conjunction with the same size "dual" tires on the rear traction wheels.

ONLY TWO MIDLAND MODELS, K AND L

No attempt will be made by the makers of the Midland to cover the entire field with a line of cars as long as your arm, but rather, the factory will concentrate on two models, to be known to the trade as Models K and L. A short and rather hurried mention of the salient points of the design of these two will serve to put them in the position of speaking for themselves, as they are well able to do. Model K is a 50-horsepower car, with an engine of four cylinders, 4 3-4 by 5 1-2, cast in pairs, and of the L type. The wheelbase 118 in., the tires 36 by 4, the body well upholstered, and the price $2,250. Passing on to Model L, that is a car of 115 in. wheelbase, and 34 by 4 tires, equipped with a 4-cylinder engine of 4 1-2-in. bore and 5-in. stroke. The makers rate it at 40 horsepower. These cylinders are of the T-head type, differing from the larger ones, but like them, cast in pairs. The clutch of this car, both models, will be remembered as one of the first of the three ring metal-to-metal clutches. The same form is used to-day. This model sells at $1,800. A very light weight for the complete car is claimed. Frictional losses are lowered to the minimum possible point by the liberal use of ball and roller bearings throughout. Ball-bearings are used in the clutch, front, and rear axles, while the transmission is mounted upon tapered rollers. The material used in the crankshaft, transmission gears, shafts and other parts which have to take the brunt of the work, are selected for high kinetic qualities, and, in order to accentuate these qualities the parts are suitably heat treated before use.



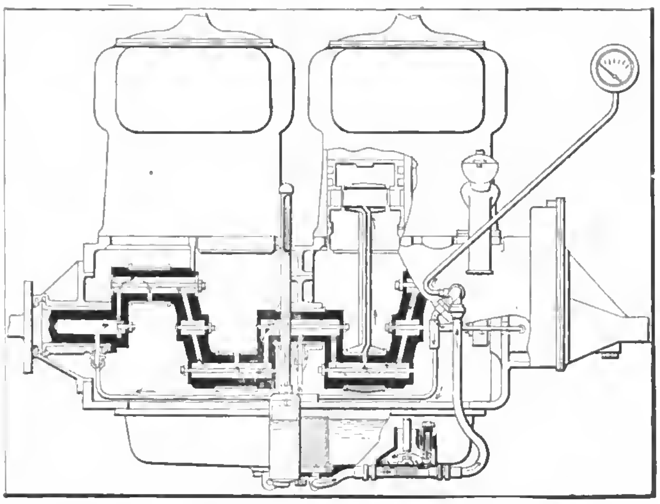
Oiling system of Lozier Light Six, the path of the lubricant from the pump to dashboard, to bearings and return being indicated by the small arrows.



Above, new Columbia lubricating scheme, the diagonal rod adjusting by its position the amount of overflow, and thus, the level in the case. Below, the Oldsmobile lower half of crankcase, showing overflow ports and at the right, the way the connecting rods dip in the oil.

MITCHELL MODEL S IS A "SIX"

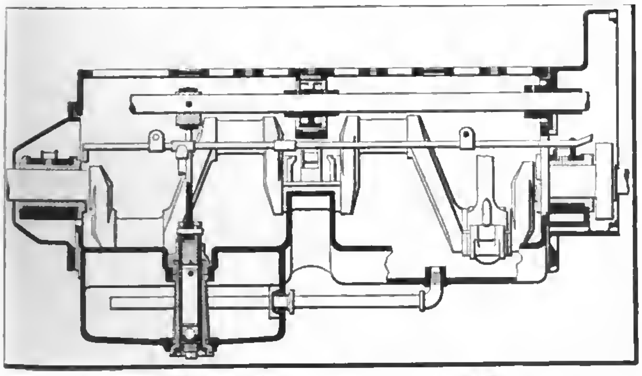
While there is a certain similarity between the respective models of the Mitchell, even so, differences in engineering detail are instituted in accordance with the designing requirement. In the six, for illustration, the frame, which has to do duty with a long wheelbase, is prevented from sagging by a heavy reinforcing plate which is riveted to the side bars at the point of narrowing and for a considerable distance along the frame; this reinforcing plate adds rigidity to the bars and fully offsets the cranking moment. The cylinders of the Model S are cast in pairs; they are nested symmetrically on a well-designed crankcase, and straight-line designing obtains throughout the work. The rear suspension is through a three-quarter platform type of springs with a lateral member faced to the rear, and the support is by means of a stout bracket which is riveted to the rear cross-bar of the chassis frame, which bar is especially designed in view of the work it must do, and the corner fastenings at the intersections of sidebars are also strengthened. The brakes, of which there are two sets, in conjunction with a pressed-steel drum for each rear wheel, connect by means of straight-line rods to the operating shaft which crosses in front of the spring suspension, and between this shaft and the pedal control an equalizer is placed for each set of brakes, thus assuring equality of pressure at the instant of application, and skidding at this critical moment is thereby thwarted. In Mitchell cars, pressed steel is utilized to a very considerable extent, and castings are, therefore, not employed. The life of these cars is lengthened in view of the character of the kinetic materials used, and what is equally to the point, the cost of upkeep becomes a negligible quantity.



Marmon is well known for the bored-out crankshaft, this being done to furnish a channel for the lubricating oil to circulate through. The arrows show its progress to the bearings.

MOLINE $1,500 MODEL IS POPULAR

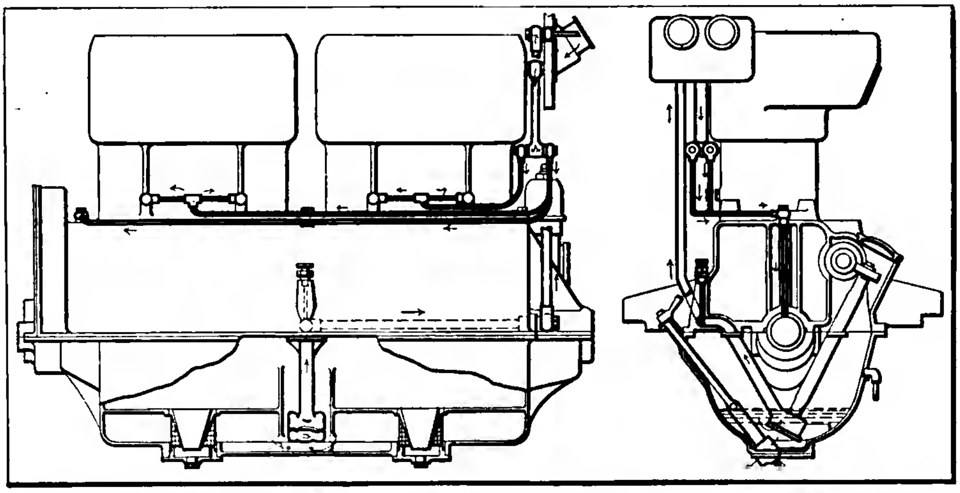
This model has a four-cylinder motor which is rated at 25.6 horsepower (A. L. A. M.). An illustration given elsewhere shows how the transmission gear is connected with the motor case by a pair of I-section arms which sweep around the flywheel. The cylinders of the motor are in pairs, with a bore of 4 inches and a stroke of 4 1-2 inches, which puts the motor in the long-stroke class. The radiator is of the tubular type; ignition is by a Splitdorf magneto and a battery auxiliary, and the power is transmitted by a cone clutch through a three-speed selective transmission gear and propeller shaft with suitable universal joint to a live rear axle of becoming characteristics. The motor bearings, including the crankshaft, are plain, but roller bearings take the exacting work at all other points. This car weighs 2,100 and has 34 by 3 1-2-inch tires on all wheels. Among the features which make it possible to class this automobile in standard practice is an I-section front axle, which is die forged and heat treated, the special steel channel-section frame, with scroll full elliptic springs in the rear and half elliptic springs in front. The cooling belongs to the thermo-siphon class, of which there is a large school, and the control for the carbureter and ignition are properly nested on the top of the steering wheel. Accessibility attains at every point in the construction of this car, and the character of the workmanship which is displayed in the power plant and elsewhere, is up to a fitting standard of Moline work.



Crankshaft lubricating method used on the new four-cylinder Reo, the plunger pump in the oil well furnishing a supply to the bearings through horizontal tubes. Pump drive is by eccentric.

MORA PRODUCES A NEW LIGHT FOUR

Besides the favorably known Mora Forty, this company will this season produce a new light car, to be known as the Mora Twenty. Besides being small, of comparatively small power, it has the merit of not being very high in price. The motor is of four cylinders, cast in pairs, water-cooled and by the thermo-siphon action. Cylinder sizes are 3 1-4 bore and 3 1-2-in. stroke. It is a very neat little power plant and attracted much favorable attention at the Palace Show, where it was seen for the first time. Ignition is by both magneto and battery. The transmission, located at the rear axle, affords two speeds and a reverse, operating selectively. The wheelbase is 84 in. for a two-passenger runabout body, while the tread is standard. Engine bearings are plain, but elsewhere rollers are used liberally. Thirty-two by 3-in. tires are used for both front and rear wheels, which size is ample in view of the fact that the weight is but 1,300 pounds. To add to the attractiveness of the mechanical features taken as a whole, a Renault type of sloping bonnet is used with a dashboard radiator. This gives a very Frenchy effect, while actually adding to the effectiveness of the cooling system. Model Forty is about the same as last year, with the



On the American motor, the oil pump is set on an inclined shaft, which is worm-driven from the crankshaft. Besides the bearing leads, there are two for the cylinders, each one dividing and supplying two cylinders. The usual telltale on the dash is used.

exception of more power, brought about by an increase in the bore of the cylinders, which now measure 4 1-2 in. in diameter. Aside from the cooling system, in which a centrifugal pump is used to circulate the water, the details of the larger car are like the smaller one just described. The little car sells at $1,050, while the price of the Forty is $2,500.

OAKLAND FROM THE BIG PLANT AT FLINT

The product of this plant is divided into two units, one of which is a popular priced car, at $1,250, and the second sells for $1,700. The smaller of the two cars has a four-cylinder motor, with a 4-inch bore, and like stroke. The cylinders are cast in pairs and cooling is done by water, which is handled

A—Shows a Cincinnati milling machine in the Excelsior plant with a large inserted milling cutter facing off the bottom flange of a T-head twin cylinder.

B—A milling machine in the National plant, mounting straddle mills and facing off the crankpin enlargements of four connecting rods, the latter being held in place by clamps against the face of an angle plate.

C—Special heavy milling machine in the Premier plant, with large inserted tooth, cutting discs, facing off port bosses on Premier twin cylinders. The milling cutters are set to straddle the cylinder, thus completing the facing on both sides simultaneously.

D—A heavy vertical mill in the Inter-State plant, with an inserted cutter head, facing off the aluminum top half of an Inter-State motor crankcase.

E—A No. 4 Cincinnati milling machine of the vertical type, with an inserted cutter milling head facing off enough cylinders for one time as used in Excelsior motors.

F—Special milling attachments on an Ingersoll milling machine as used at the Rambler plant for facing off the bottom flanges of enough cylinders for one motor at one time.

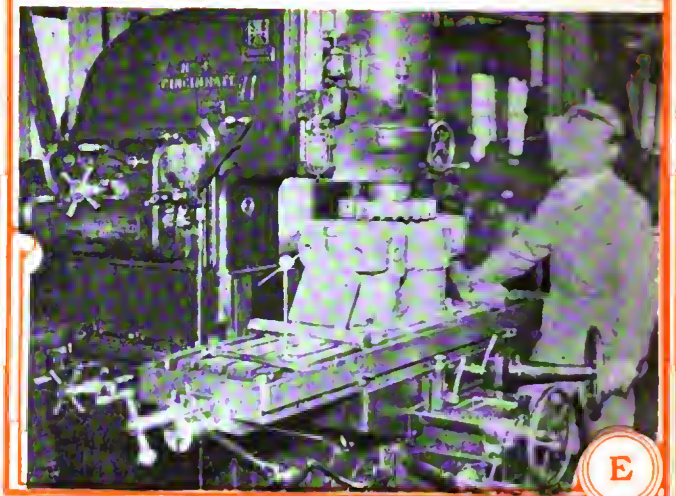


PLATE V.

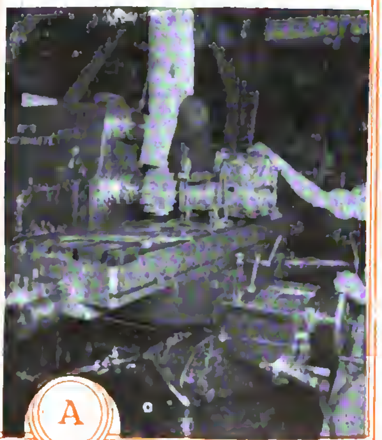
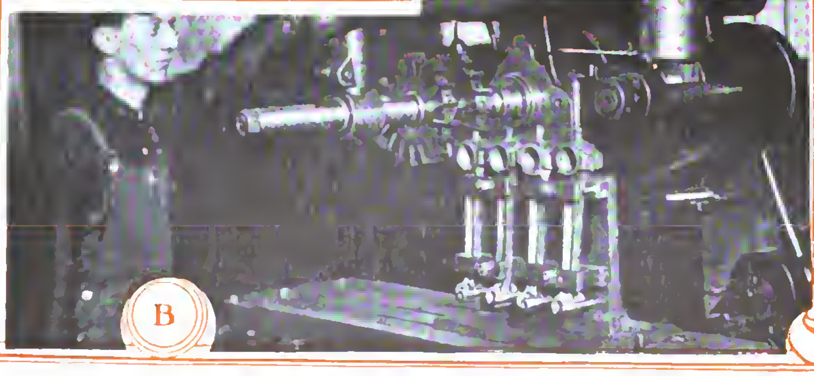
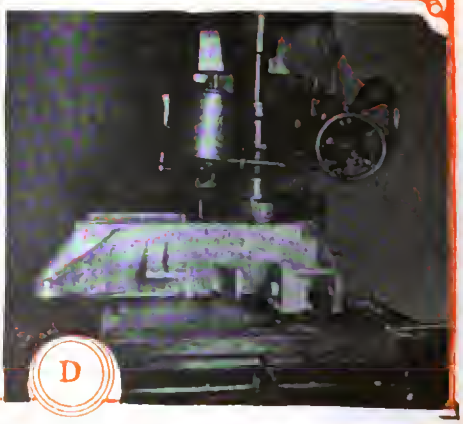
ACCURATE AND QUICK MILLING







K

by a centrifugal pump through a tubular radiator. Ignition includes a magneto, and oiling is positive, a pump serving for the purpose. In the mechanical control, a disc clutch co-operates with a selective three-speed sliding gear and the 100-inch wheelbase, with a 56-inch tread, adds to the good performance of the car. This car rolls on anti-friction bearings, weighs but 1,800 pounds, and 32 by 3 1-2 inch tires on all wheels have an easy time of it. The plant, which has assumed enormous proportions of late, is one of the large undertakings of the year, and a visit to this establishment makes one of the most pleasant surprises which a newcomer is likely to experience in the rounds of this big infant industry. Elsewhere in these pages is to be found a cut of the rear end of the Oakland runabout, showing rumble seat and gas tank.

G—Special milling machine of the Ingersoll type as used in the Metzger plant for facing Everitt motor cases in gangs. This is an excellent illustration of the most modern practice.

H—Special vertical mill as used in the National plant for reaming connecting rods to an exact size and other precise work of an equivalent character.

I—Vertical mill in the Excelsior plant, with a large inserted tooth cutter, used for facing off motor cases and kindred work.

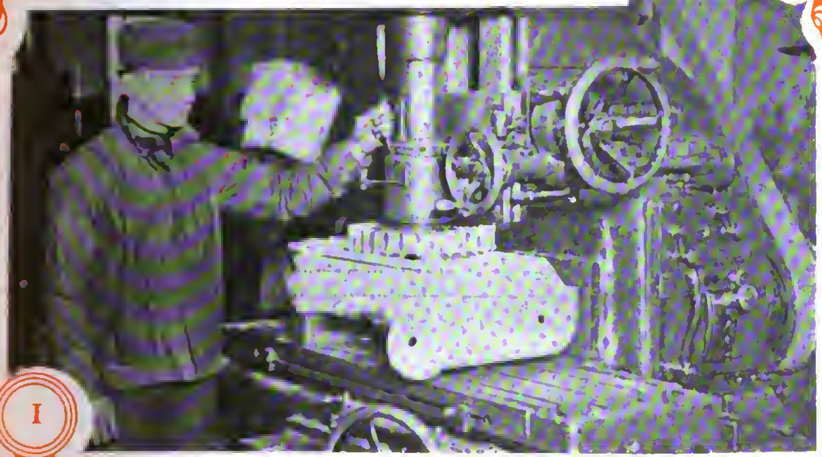
J—Garvin mill in the Moon plant with a large inserted tooth cutter facing off the upper half of an aluminum crankcase.

K—Brown & Sharpe gear cutting milling machine as used in the Moon plant, shown in the process of cutting half-time gears employing the fixed cutter principle.

L—Special cylinder boring machine with four spindles so arranged as to fix the centers and bore cylinders of the block type as used in Everitt motors made by the Metzger Manufacturing Company. This is the type of design and type of machine tool which may truly be characterized as right up-to-date, the tool allowing of the rapid and very economical production of the motor as turned out by the designer of the car. Without a doubt this skillful workman knew of the possibilities.

L

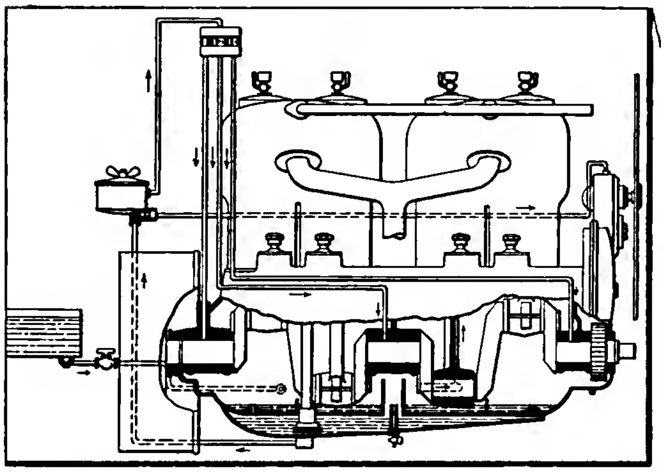
G



I

J

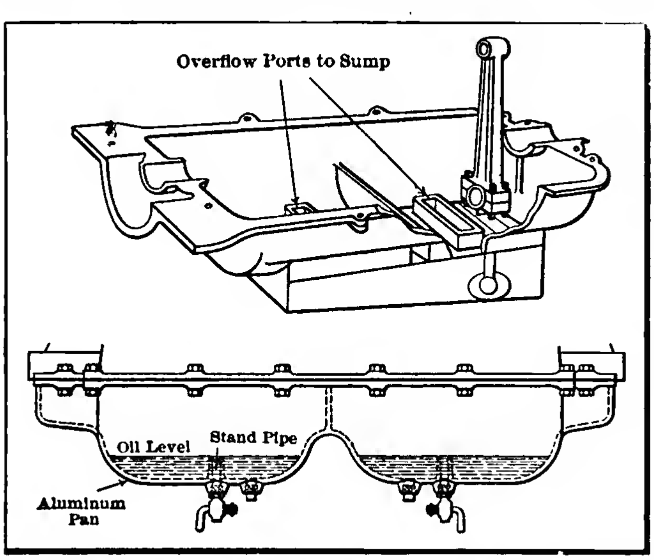
H



Circulating system of lubrication as adopted by the Royal Tourist. The pump forces oil through sight-feeds on the dash to the three main crankshaft bearings, and also to the timing gears; the strainer is very accessible.

CLOSE COUPLED OLDSMOBILE LIMITED POPULAR

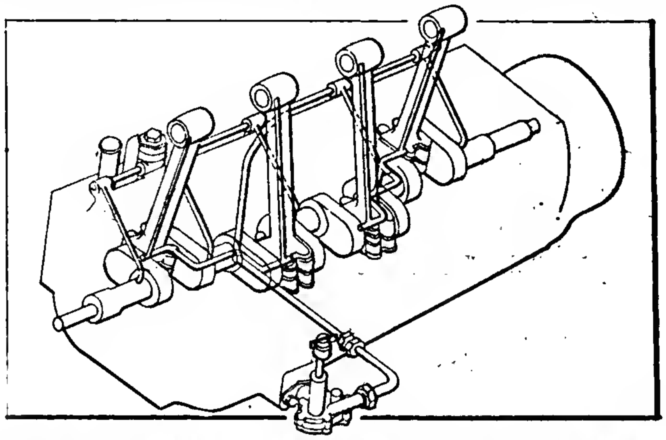
This car, which is listed at $4,600, has a wheelbase of 130 inches, standard tread, and the distinction of using 42 by 4 1-2-inch tires on all wheels. The brakes for the foot-lever control are external on the rear wheels, and the brakes, which are under hand control, are internal extending on the rear wheels. This car has a six-cylinder motor with a bore of 4 3-4 inches, and a stroke which brings it into the class with the squares. A cellular radiator in conjunction with a pump maintains a sufficient cooling, and the ignition under working conditions is by means of a Bosch magneto; since the dual system is employed, emergency ignition is cared for in the same system. The transmission is a selective type with four forward speeds and reverse, so that in road work the car performs under the best conditions of economy, with the added advantage of a high rate of acceleration, due to the fourth speed in the transmission system. The leather-faced cone clutch is of the latest and most approved design, and easy riding is assured by the application of semi-elliptic springs in front, and three-quarter elliptic springs of great capacity on the rear axles, they being 54 1-2 inches span, and the plates are 2 1-4 inches wide. This car has the further advantage of a baggage rack, coat rail, foot rest, top, speedometer, glass front, Prest-O-Lite tank, and 9-inch headlights.



Two ideas of lubrication contrasted: Above is shown a crank-case in which a separate trough is provided for each connecting rod big end; below is the Locomobile idea, in which two big ends share the same trough.

FOUR PACKARD MODELS TO A DISCRIMINATING PUBLIC

From the "Eighteen" which is a runabout at $3,200, to the "Thirty" as a touring car at $4,200, is the normal span of Packard endeavor, which is not taking into account any of the body creations as limousines and landaulettes, of which the Packard plant has produced many noteworthy examples. The "Eighteen" as well as being a runabout of distinction, is also fitted out with a touring body for such of the Packard clientèle as expresses a preference for more seating capacity. The "Eighteen" motor is a characteristic design, with four water-cooled cylinders, 4 1-16 by 5 1-2 inches bore and stroke respectively, the cylinders being cast in pairs. Cooling is accomplished effectively by Packard honeycomb type of radiator, and the water is circulated by a centrifugal pump. The main ignition system consists of an Eisemann magneto, and for auxiliary work, a coil and storage battery is employed in each of the models. The transmission gears for all the models, as well as the "Eighteen" is a three-speed selective with reverse, mounted on the rear axle, of which it becomes a unit. The rear axle construction in cars of this make, has become famous as a Packard idea, and the germ has propagated until to-day the scheme is broadly used. The "Eighteen" as a runabout, has a wheelbase of 102 inches, but as a touring car, the wheelbase is



One pump may give a positive feed to thirteen points, as is explained by the diagram showing the Knox practice. From a manifold the oil passes to the five main bearings, thence to the big ends and finally, the piston pins.

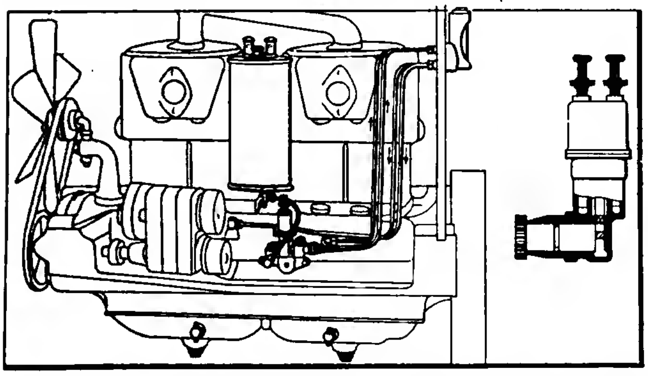
increased to 112 inches. Ball or roller-bearings are used at all points except in the motor, and in the "Eighteen" runabout model the tires are 34 by 3 1-2 in front and 34 by 4 for the rear.

PAIGE-DETROIT IS A TWO-CYCLE ROADSTER

The price of this automobile is $800, and it is provided with a 2-cycle, 3-cylinder, water-cooled motor (valveless), of rather novel design, suspended at three points on a channel section chassis frame. The bore of the cylinders is 3 3-4 in. and the stroke is 4 in. The power rating is 25 horsepower, and ignition is by a magneto. An automatic force feed oiler is used to attend to this important matter and cooling is by thermo-siphon with a radiator which is represented to be adequate for every need. The wheelbase is 80 in. and 56-in. tread, while the road wheels are fitted with 32 by 3-in. pneumatic tires. A sliding gear gives two forward and reverse speeds, the clutch is leather faced, of the cone type, and the side-bars of the frame are said to be nickel steel. The brakes are all on the rear traction wheels and consist of a working and an emergency set, the one internal expanding and the other external constricting. The car is swung low; rear cross spring is half-elliptic, and is so suspended as to enable the frame to come as close to the ground as flywheel clearance will permit of. The general appearance of the car is very much in line with advanced designing.

PALMER-SINGER LINE INCLUDES FOURS AND SIXES

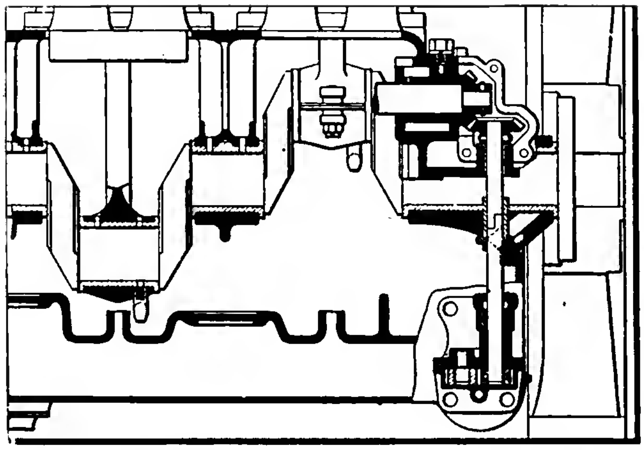
Many models at many prices, in both four and six cylinders, make the Palmer-Singer line of 1910 cars a very complete one. This must not be taken too literally for the company has abandoned the season and yearly model habit. However, the list at present includes the following models: XX, LXI, LXII and XXX enclosed bodies. The first-named is a chassis with a 115-in. wheelbase, standard tread, 34 by 4 in. tires, which for use with heavy enclosed bodies is altered to 120-in. wheelbase, while the tire equipment remains the same. The power is supplied by a four-cylinder, 4 1-4 by 4 1-2-in. engine, of which the cylinders are cast in pairs. A Bosch magneto furnishes current for the high-tension ignition system with batteries in reserve. Cooling is by water with a centrifugal pump and honeycomb radiator. Disc clutches and four-speed selective transmissions are used on all models. The price of the XXX with touring body is $2,250, and with landaulet body, $3,650. Both other models are higher powered, LXI having a six-cylinder 4 3-4 by 5 1-2 engine, rating at 54.1 horsepower, while on Model LXII, the bore of the six-cylinder engine is slightly greater, 4 7-8, and the stroke the same as before. This may be had in any body form, being supplied as a three-passenger runabout (LXI) for $3,250, and as a five-passenger touring (LXII) for $3,500.



Packard has a nicely worked-out lubrication system, employing two pumps, of the plunger type; these deliver oil through sight feeds to the two compartments of the crankcase. A reserve supply is in the tank between the cylinders.

PATERSON THIRTY AND WHAT IT SHOWS

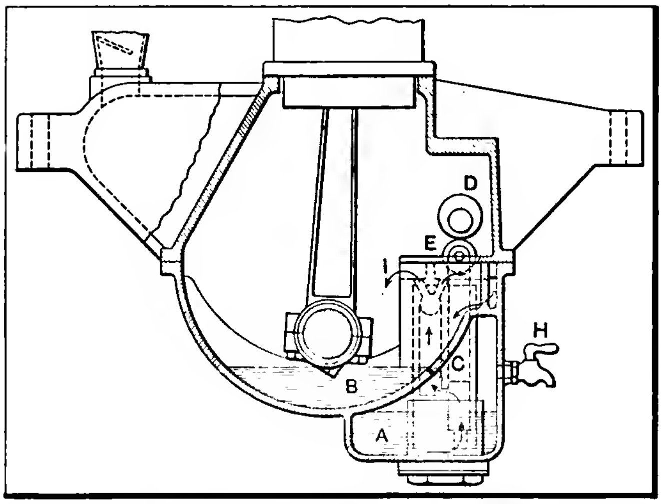
A 4-cylinder water-cooled motor, of the 4-cycle type, with cylinders cast in pairs, 4 by 4-in. bore and stroke respectively, giving an A. L. A. M. rating of a trifle over 25 horsepower. Instead of a pump being used to circulate the cooling water, a suitable radiator for thermo-siphon cooling is used, and the water piping is made accordingly. Ignition is by a double system, which includes a magneto, coil and battery. In lubricating, a constant level splash is maintained by means of a plunger pump type of lubricator. A Schebler carbureter takes up the feeding of the fuel to the motor, and control includes a type of cone clutch which is leather faced, and springs press the leather into good engagement. The transmission includes a three-speed (and reverse) sliding gear system, which is selective and engages a carbon steel propeller shaft through universal joints. The rear axle to which the propeller shaft runs is of the semi-floating type, using roller bearings; the front axle is also tubular, but the bearings are of the ball type. All brakes are on rear wheels and comprise a working and emergency system, the one being internal expanding and the other is external constricting. The gear ratio is optional within practicable limits, and the road wheels are of the artillery type, fitted with demountable rims, which take 32 by 3 1-2-in pneumatics. The wheelbase is 104 in. with a tread of 50 in., and the springs are full elliptic front and rear. With a motor of this rating and state of mechanical perfection, it is not too much to expect that the speed of the automobile will range between 5 and 50 miles per hour, and, as for appearance, it is that due to black leather upholstery, blue body, yellow gear, or certain options. It is made at Flint, Mich., by W. A. Paterson Company, a newcomer in the business.



Cross-section of Overland oil pump, of the gear type, driven by a vertical shaft and bevel gears from the camshaft. The lower half of the crankcase, with the pump, can be removed without disturbing the drive.

PEERLESS DESIGN FEATURES ARE CHARACTERISTIC

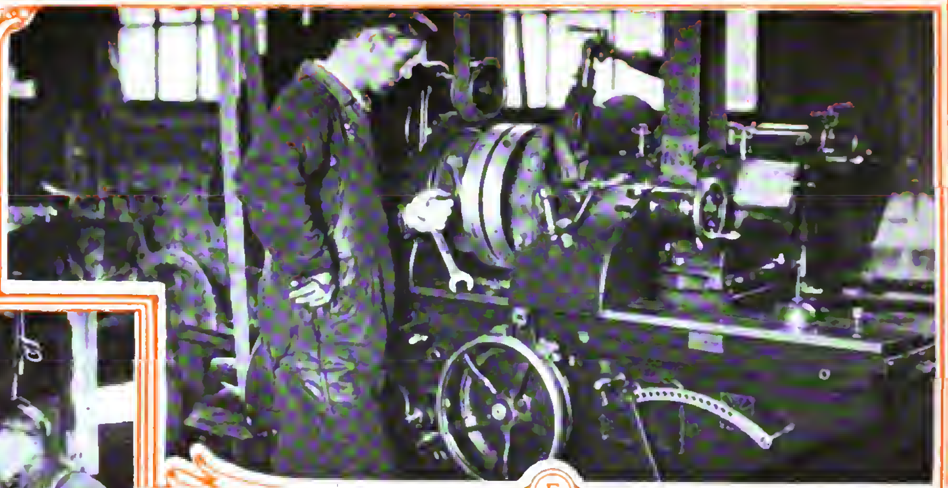
From the Model 27 at $4,300 to the Peerless "28" at $6,000, runs the gamut in the matter of size with no suspicion of a change in the standard fixed by this well-known company. These models when placed alongside of each other are excellent illustrations of consistency, in which, as the spectator is bound to observe, the things which are good in one car are equally representative in another. Model 27 has an A. L. A. M. rating of 38 horsepower, has a runabout body, with a rumble, and the motor is a 4 7-8 by 5 1-2 inches bore and stroke respectively, cylinders cast in pairs, and cooling is done with a honeycomb radiator and gear pump. A Bosch magneto serves in the main, for purposes of ignition, with a storage battery and suitable coil for the rest. Ignition is positive with a mechanical force feed, and the Peerless expansion band form of clutch is continued. All Peerless models are equipped with a selective four-speed transmission, are shaft driven, and the runabout has a wheelbase of 118 1-2 inches, with standard tread, and among other designed features which take on standard characteristics,



The Johnson Service Company uses a plunger oil pump, actuated by an additional cam on the camshaft, whereby a constant level is maintained in the crankcase. The pump is easily removable from below without complication.

PLATE VI.

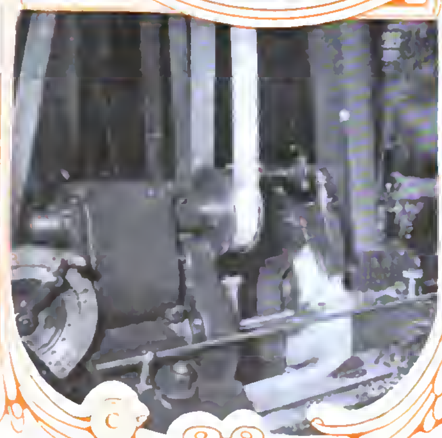
Grinding Methods Obtain



E

A

B



C

D

A—Excelsior method of grinding crankshafts, in which speed and accuracy are definitely aimed at. This is a Landis No. 24 grinder, which is much used in this class of work. In grinding crankshafts it is the practice to allow about 0.010 of an inch to be ground off, and the rough machining work is done at high speed on special low swing lathes, using Novo or other grades of high-speed cutters. The fact that the grinding is done as a final operation enables the lathe man to dig in at a rapid pace, and if the shaft does deform (back away from the tool slightly) in the process of roughing, it makes no difference in the final operation—the work will come off of the grinder properly finished.

B—In the Excelsior plant at Chicago, showing a grinder on piston rings, using a magnetic chuck on a flat plate to hold the rings during the grinding operation.

C—In the Excelsior plant, showing a new type of Landis grinder, working on integral camshafts grinding over the faces of the cams as well as between them on the round of the shaft. This tool is of the greatest advantage in this class of work, and the accuracy of the cams is much nearer than in any other way. The attachment is set up in the grinder centers, and swings away towards the work in conformity with the shape of the cam, a master cam of the required shape being responsible for the travel of the work in its relation to the grinding disc.

D—In the Rambler plant at Kenosha, showing a Besley grinding machine in the process of grinding off the ends of spiral springs, which, in turn, are placed in holes in a fixture which was contrived for the purpose.

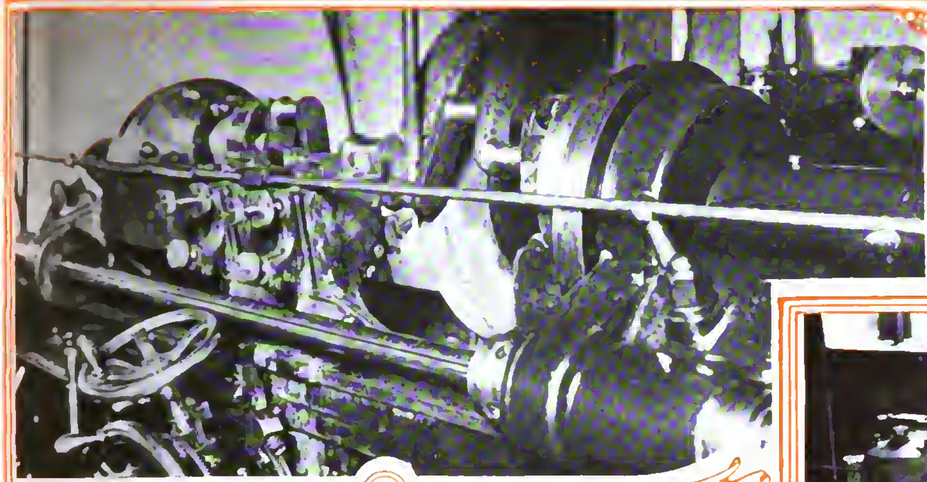
E—In the National plant, grinding the faces of expanding brake shoes.

plain bearings are used in the crankshaft, but ball-bearings obtain for the rest, they being of the annular type. In all Peerless cars the tires are 36 by 4 in. front and 36 by 5 in. rear.

A new little car has just been brought out, which has all of the best features of the larger cars, and a number of little individual characteristics of its own. Thus, the driver, with all control levers is located on the right-hand side.

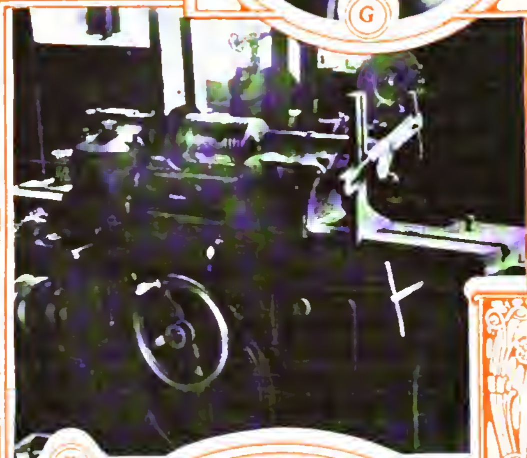
PENNSYLVANIA HAS VALVES IN CAGES

The illustration which is given of the motor under discussion shows how the valves which are in the heads may be readily removed for inspection and grinding, or they may be ground in place. There are four Pennsylvania models with power plants ranging from 28.9 to 54.1 horsepower, and the larger size is a "Six" with a 4 3-4 by 5 1-2 inches bore and stroke of cylinders respectively, cast in pairs, water-jacketed, cooled by circulation from a gear pump through a cellular-type radiator, and the ignition is by Bosch magneto with a battery auxiliary. The magneto is placed on the left side of the motor back of the gear pump, and the pump in turn takes its power from a gear which meshes with one of the half-time gears. All gears are in a grease-tight housing at the front end of the motor, and the magneto, which is on a shelf extending out from the top half of the crankcase, is flexibly mounted so that it may be removed and inspected without causing annoyance in the act of replacement after inspection, or if repair becomes a necessity. There are many other points of mechanical merit, as the full floating clutch type of rear axle, selective three-speed and reverse transmission gear, with the gears of nickel steel—the spindles float on annular type ball-bearings. This maker is one of the few—the list includes Packard, Glide, Moon, Mora, Otto, Overland, Stearns, Sterling, Watt, Welch, and others—locating the transmission as a unit with the rear axle, the differential case housing the gears and shafts.



H

G



F

F—In the Moon plant, showing a grinder working on pistons to bring them to exact size. Grinding pistons is a special process or operation, which is conducted in the plants which are doing work of the very accurate sort.

G—In the Thomas plant, showing an application of a flat grinder fitted with a magnetic chuck.

H—In the Inter-State plant, showing a grinder on crankshaft work.

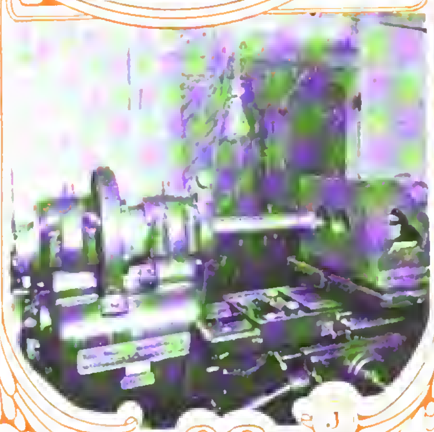
I—In the Metzger plant, showing an application of a surface grinder, facing plates to make the joints tight, and eliminate the use of packing.

J—Heald grinder on cylinder work in the Excelsior plant, showing the cylinder bolted to an angle plate and the grinding disc on the end of a long, tapered spindle, which is eccentric to the bore of the cylinder. The result is very accurate as respects the character of the work, and the time required is much shortened over that of other methods. The method of setting up the cylinders is not the same in the several plants, and, in some cases, a turntable is employed, it offering the advantage of allowing the workman to set-up while the grinder is working.

K—Pratt & Whitney surface grinder in the Excelsior plant finishing (by grinding) plates as used on Excelsior motors, the idea being to make all joints tight by grinding rather than by the use of packing. A magnetic clutch holds the work in place on the platen of the grinder. This grinder is normally available for all classes of surface grinding work and the magnetic chuck is very useful in making quick and accurate adjustments of the work in the setting-up process. In some shops this form of grinder is used for facing off manifolds, and, since the facing is done with great accuracy, it is unnecessary to employ packing under the faces of the manifolds, so made, to maintain tightness.

I

K



J

PIERCE-ARROW STAGES SIX SIXES

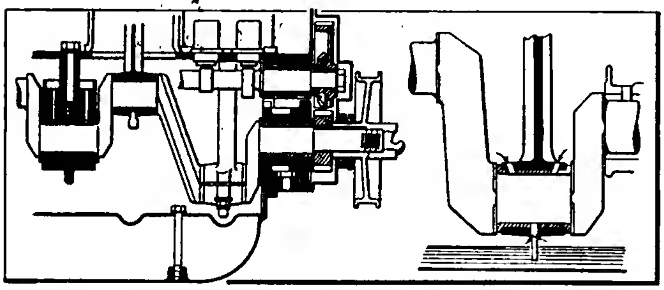
There are two models of the "Thirty-six," as many more of the "Forty-eight," terminating with an equal number of the "Sixty-six." Possibly the runabout "Thirty-six," at $3,850, is the popular type for the man with red blood in his veins, but for real comfort, and touring under pleasurable conditions, a selection from the more pretentious models offers wide possibilities. The runabout "Thirty-six" has six cylinders, 4 by 4 3-4 bore and stroke respectively; they are cast in pairs, and a honeycomb radiator, aided by a centrifugal pump, is responsible for the cooling. Ignition is by Bosch magneto, with a storage battery and suitable coil auxiliary, while lubrication is on a most ambitious basis, as illustrated elsewhere in this paper. All Pierce models are shaft-driven, and the runabout model under discussion has a wheelbase of 119 inches, with a tread of 55 inches, pressed steel frame, plain bearings in the motor, Timken roller-bearings in the road wheels, and annular type ball-bearings elsewhere. The tires on this model are 36 by 4 all around, in fact, this maker is addicted to very large tires, which will be found on all models, regardless of power.

POPE-HARTFORD OF MANY UNEXCELLED FEATURES

Model T sells for $2,750, has an A. L. A. M. rating of 29.7 horsepower, and is built for touring. The power plant includes a four-cylinder motor with cylinders 4 5-16 by 5 1-8-inch bore and stroke respectively, cast in pairs, water jackets integral, and cooling is accomplished through circulation by a centrifugal pump, feeding a characteristic type of Pope-Hartford radiator. Ignition is by Bosch magneto, with a storage battery and coil as supernumerary, and lubrication is positive through the good office of a pump. The cone clutch is of such excellent design that flywheel effect is eliminated and strength obtains to an adequate extent. Speed changes are depended upon primarily, due to the excellent flexibility of the motor, and then, by suitable manipulation of a three-speed selective type transmission gear, with reverse of course. The I-section frame of special steel is shaped to sustain under the conditions imposed, taking into account a 118-inch wheelbase, and a tread of 56 inches. The motor has three plain bearings and for the rest roller-bearings are used, and an illustration, which is afforded, will show how thoroughly well the straight line·idea in designing obtains throughout the cars of this make.

FOURS ONLY FROM YORK PULLMAN FACTORY

Four four-cylinder models will comprise the entire output of the Pullman factory at York, Pa. These are styled O, K and M, selling at $1,650, $2,000 and $3,500 respectively. There is another newer model also a four, which sells at $3,000. The motor on the lowest priced of the lot is of 4-in. bore and 5-in. stroke, while that of Model K is larger, being 4 1-2 by 4 3-4, a larger bore but a shorter stroke. The newer model has a still more powerful engine, the dimensions of which are 5 by 5 1-4, a still shorter stroke relative to the bore. In the highest-priced car, Model M, a 45-horsepower engine is utilized, the sizes of which are 5 1-4 by 6, which is again a long stroke as compared with the bore. In all of these models, the cylinders are cast individually, the ends being given up to a very large core opening. The ends, too, are flanged and these flanges are finished so as to bolt up close to one another. When set into place, each cylinder thus is bolted fast to the one on either side, making the whole as a block casting, yet insuring clean, accurate castings

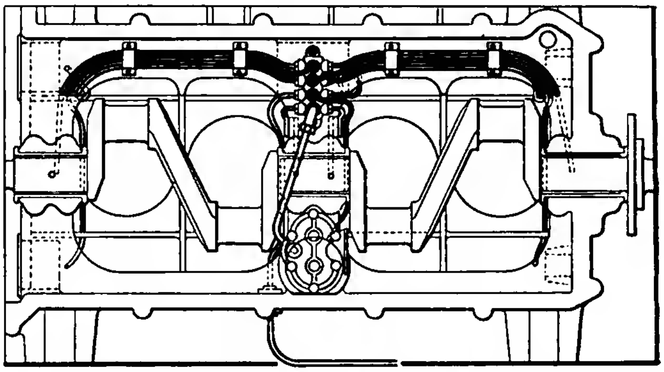


Inter-State uses flattened scoops on the caps of the connecting rod big ends to secure for these their supply of oil; National, as shown on the right, has in addition two oil holes drilled through on the upper side.

and no trouble with cores. The water—circulated by centrifugal pump—passes in at the rear core plate, thence around the last cylinder, into the third through the very large opening at the end of the cylinder casting, and then on through the other two cylinders in a similar manner, to the front, where it passes up and out to the cellular radiator. All models have standard tread, the wheelbases increasing with the power and price as follows: 108 in., 112 in., 110 in. and 124 in. Engine bearings are five in number, one between each pair of cylinders and one at each end, and of the plain type. All transmissions run on balls, while for the axle, rollers are used exclusively. Weight, always an important question, has been well cared for and properly proportioned. The weights vary upward thus: 25.6-horsepower touring, 1,800 pounds; 32.4-horsepower touring, 2,400 pounds; 40.0-horsepower roadster, 2,600 pounds; and 44.1-horsepower seven-passenger touring, 3,500 pounds.

THREE BIG-VALUE RAMBLERS FOR 1910

Figures have been utilized to designate the three models, which the immense Kenosha factory will produce in large quantities during the present season, these being Models Fifty-three, Fifty-four and Fifty-five. Of the three, the last-named, Fifty-five, is the big car. This is rated at 45 horsepower and has a three-speed transmission, operating selectively, of course. It is a big roomy touring car, seating seven comfortably. The selling

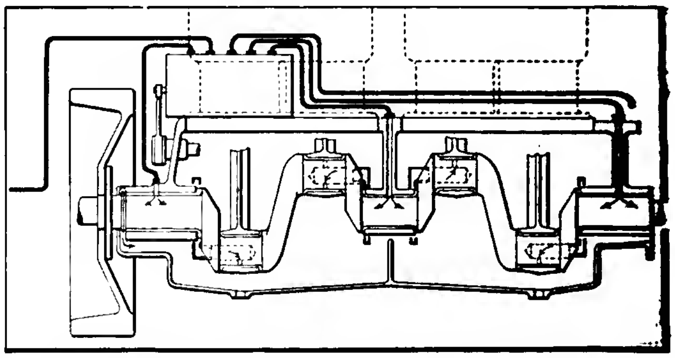


On the Stoddard-Dayton the oil is distributed through individual pipes from a manifold in the middle of the case; the pipes are accessible for inspection on removing the lower half of the crank-case, which may be done readily and quickly.

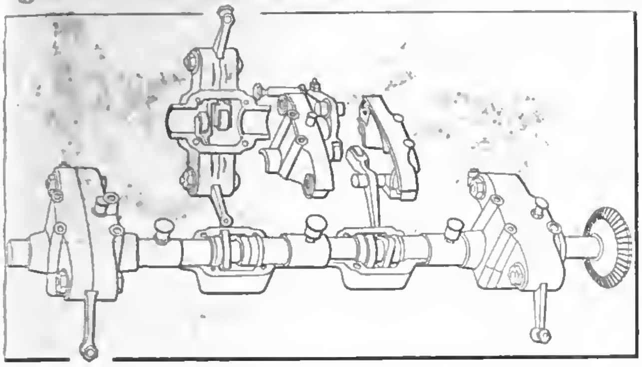
price is $2,500, at which figure is included magneto of the high-tension type and from a reputable factory, full set of five lamps, gas tank for the headlights, and tool box containing a set of tools. This, it will be remembered, is one of the Rambler cars which carry the spare wheel with fully inflated tire on the right-hand side, handy to the driver. The running board is notched to let the lower part of the spare wheel rest in it, thus saving space, and insuring a tight hold on the wheel. In case of tire trouble, punctures, or any simiuar emergency, it is a matter of but a few moments' work to remove the defective member, substitute the extra one, and go on one's way.

REGAL A WELL-KNOWN THIRTY HORSEPOWER CAR

This make is delivered in three models, B, F and E. The price is $1,250, and the rating is (A. L. A. M.) 30 horsepower. Model B is a runabout; F is a touring car, and E is a baby tonneau. The power plant is common to all and comprises a motor of the water-cooled 4-cylinder type, using a patented thermo-siphon system, and the cylinder dimensions are 4 by 4 inches. The cylinders are cast in parts, ignition is by Remy magneto, with a coil and battery as auxiliary. Lubrication is by regulated splash, bearings for the crankshaft are a special grade of white metal, and the method of scraping in and inspection is thoroughly good in every way. The clutch is of the cone type, and the transmission gear is a three-speed (with reverse) selective, placed on the chassis frame in a mid-position. Two universal joints are placed in the propeller system which lead to the live rear axle, and Hyatt nickel steel roller bearings are used at all important points, including a special bearing which is placed at the axis of the universal joint on the end of the shaft tube to resist the loading at that point and relieve the clutch mechanism of any but its normal work. The weight of the car is 2,000 pounds, body work is of steel on stout, well ironed, wood framing and special



Pennsylvania retains the time-tried individual pump system; in this case the feeds are to each of three crankshaft bearings, from which the big ends are supplied, another to the timing gears and a fifth to the gearcase.

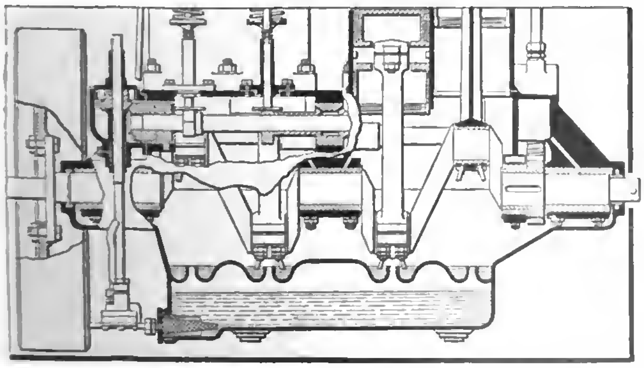


Overhead valve systems are hard to lubricate properly, but in the Jackson the problem has been satisfactorily solved. The parts are completely inclosed from dust, and oil and grease cups are liberally employed.

means is provided to eliminate noise in the body work as well as in the machinery. The tires used are 32 by 3 1-2-in. pneumatics front and rear, and the earmarks of skilled designing is to be seen at every point. Made by the Regal Motor Car Company, Detroit.

CONCENTRATION THE ROYAL TOURIST KEYNOTE

The new Model M will occupy the attention of the entire factory of the Royal Tourist Car Company, this year, being the only car put out. This has a four-cylinder, water-cooled, fourcycle engine of large size. The cylinder bore is 5 1-2 in., and the stroke, 6 in. This gives an unusual power output, although rated at but 48.4 horsepower by the usual formula. At to detail, the cylinders are cast in pairs, with valves on opposite sides. Those for the inlet are placed on the left, as is also the Bosch high-tension magneto. To the right are to be found the exhaust valves and pipe, as well as the gear-driven pump. For varying the speed of the car, four forward speeds are provided in the transmission, these operating selectively. The transmission has a mid-location, and drives to the rear axle through a very slightly inclined shaft. Motor reactions are well cared for in the bridge-constructed torque rod, while the alignment of the rear axle is maintained by means of distance rods, stout dropforgings. Brakes are unusually large and efficient, five in number, and assisted by sprags, which are attached directly to the rear brake drums, so that it is impossible to back down a hill when the sprag is in use. The wheelbase is very long, 126 in., while the springs, too, have good length. Moreover, the latter are of alloy steel, selected for this purpose. The front springs are short and very flat, while in the rear, a platform type of suspension is used. The 12-spoke front wheels are 36 in. in diameter and carry 4 1-2-in. tires, while the 14-spoke rears are of the same size, but carry 5-in. tires. The price varies with the body, being $4,500 for the touring, close-coupled cars, and roadster, $5,700 for the limousine, and $5,900 for the landaulet.



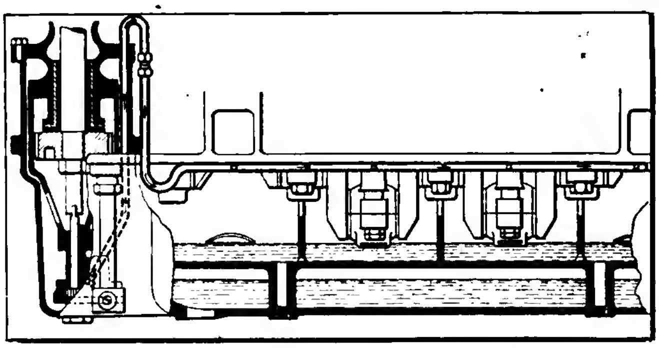
The circulating pump system of lubrication is used by Haynes, with an unusually large reservoir in the crankcase base. Each big end has its individual oil trough with overflow hole to prevent an excess of lubricant.

TWO MODELS--TWO CHASSIS FROM FATHER SELDEN

In the modest-priced class, are to be found two models, of which "The Father of Them All" is justly proud. These are the two Selden products, known as Models 35 and 29. Just as one would think, the higher numbered model has the higher powered engine, but the lower price. The former is rated at 36.1 horsepower with four 4 3-4 by 5-in. cylinders. The latter, on the other hand, has a similar number of cylinders measuring but 4 1-4 by 4 1-2 in. Both engine cylinders are cast in pairs, cooled by water circulated by centrifugal pump, ignited by storage battery with magneto as an extra, lubricated by splash and an oil pump, each utilizes a cone clutch, a three-speed selective gear set located on the main frame midway between engine and rear axle, shaft drive, pressed steel frame, plain bearing engine and roller-bearing transmission and axles. The higher-priced car is Model 29 at $3,000 for a six-passenger limousine. This has a 114-in. wheelbase, standard tread, and 34-in. wheels, with 3 1-2-in. front and 4-in. rear tires. The price of Model 35 is $2,000 for a five-passenger body. The wheelbase is 116 in. and the tires are the same as the larger model. The weight of Model 35 is given as 2,650 pounds.

STEARNS IS MADE IN FOUR DIFFERENT MODELS

In the Stearns line of automobiles the range is between $3,200 for the Model 15-30 and $6,500 for the Model 45-90. The 15-30

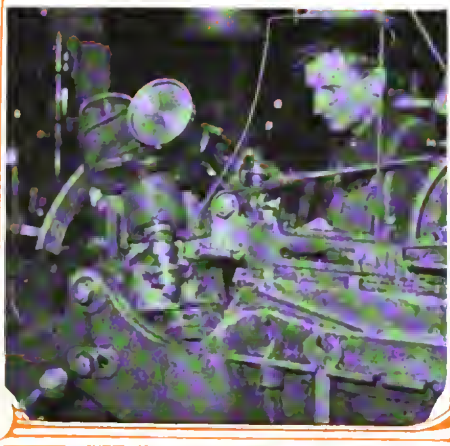


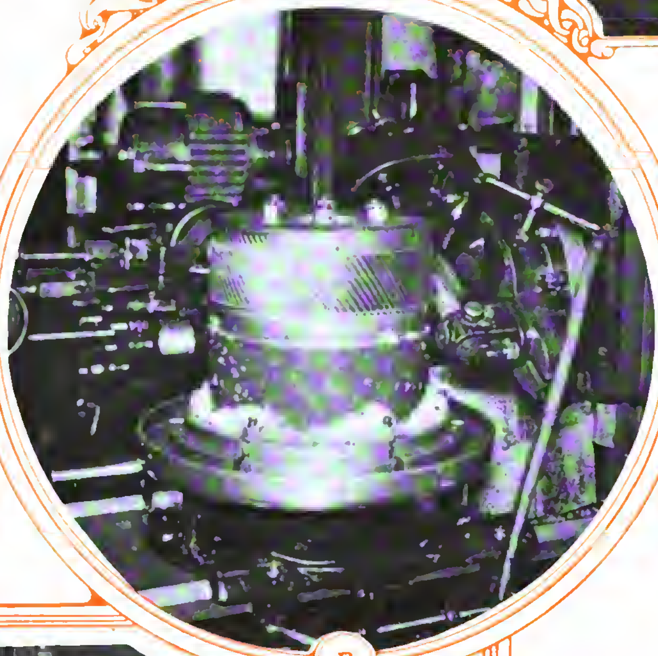
Rutenber motors, which are used on many well known cars, rely for lubrication on the splash from the connecting rods; the compartments are kept filled by a gear pump driven by a vertical shaft from the camshaft.

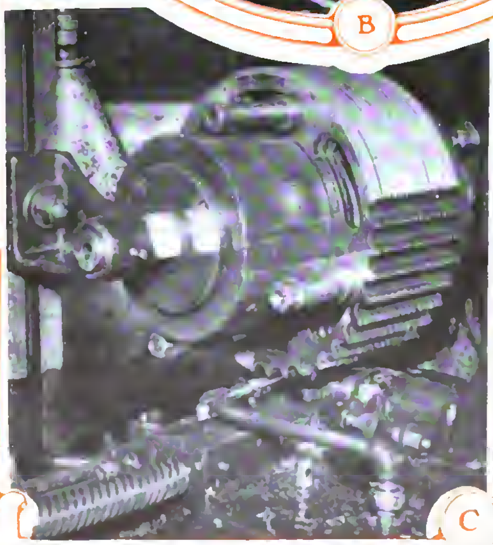
has an A. L. A. M. rating of the motor of 32.4 horsepower, is built for touring and seats five, and the power plant is a four-cylinder type, the bore and stroke being 4 1-2 by 4 5-8 inches, with the cylinders cast in pairs, placed vertically in the conventional way. Ignition is by a Bosch high-tension magneto, with a dry cell and coil auxiliary; lubrication is positive with a pump, and a multiple disc clutch serves to regulate the power control between the motor and the three-speed selective transmission gear, while the axle, which was previously illustrated in The Automobile, is of a special I-section with two branches mounting the gear system in the bow thus formed. The wheelbase is 116 inches, with a 56 1-2-inch tread; ball bearings of liberal sizes are used at every point, and the weight of the car is 2,650 pounds, supported by 34 by 4-inch tires on all road wheels. The character of the work as it will be found in Stearns cars involves the use of alloy steel to a very considerable extent, and selected grades of "special heat" carbon steel are employed in such parts as experience dictates. The springs upon which the chassis frame suspends are, with wide plates, made of alloy steel, and eyes at every point are reamed, bushed, and provided with grease cups. As a further indication of the character of the Stearns work, reference may be had to the transmission elsewhere in this article.

PLATE VII.

How Gears are Fashioned







A—Bilgram bevel gear shaper cutting teeth on a differential gear. This type of tool was utilized in many plants for the purpose of making accurate bevel drives and free working differentials. This photograph was taken in the Woods plant.

B—In the Woods plant, showing a German system of hobbing gears, the particular example being that of the spiral gear as used in the transmission system on Woods Electrics.

C—Showing sprockets being cut on a Gould & Eberhardt automatic gear cutter. This is another example from the Woods plant, and indicates the method by which a gang of sprockets are cut simultaneously.

D—This is another example from the Woods plant, and illustrates a La Pointe broacher, which is used in many shops for broaching square holes in gears, sprockets, and other transmission parts.

E—Excelsior motor in the process of having the half-time gears assembled.

FOURS AND SIXES IN STEVENS-DURYEA LIST

These well-known advocates of the three-point suspension as a sure cure for all automobile ills will turn out just two models in four cylinders and two in six cylinders. These are Models XXX and X, fours, and Models AA and Y, sixes. The first has a 4 3-4-in. bore but a short stroke of only 4 1-2. The same engine is used in Model X, also. This has the cylinders cast in pairs, as do also the larger engines. On Model XXX, the wheelbase is 109 in. and on Model X it is 124 in. The former, called a 36.1 horsepower unit, is regularly equipped with a three-passenger body, and in that form sells at $2,850. The same price covers Model X, which is had with a five-passenger touring body. Large wheels are used on both, in fact, on all models, those on the two larger types being 36 by 4 1-2 in. all around on Model AA, and 36 by 4 front and 36 by 5 rear on Model Y. The last is powered with a six-cylinder engine 4 3-4 by 4 1-2, rated at 54.1 horsepower, and has a 142-in. wheelbase for a seven-passenger touring body, in which shape it sells at $4,000. The only other model not described is AA, which has a six-cylinder engine with a bore of 4 1-4 in. and a stroke of 4 3-4 in., the only engine built by this firm not having a "short" stroke. This is rated at 43.8 horsepower, and the chassis when fitted with a five-passenger body sells at $3,300. It has a 128-in. wheelbase. On all models engine bearings are plain, transmission bearings ball, while axles run on balls also. All four models have a progressive gear box giving three forward speeds, this form of a gear having been used by this company continuously. The driving shaft of these cars presents much of worth, in that it is a continuous series of tapered squares and squared holes.

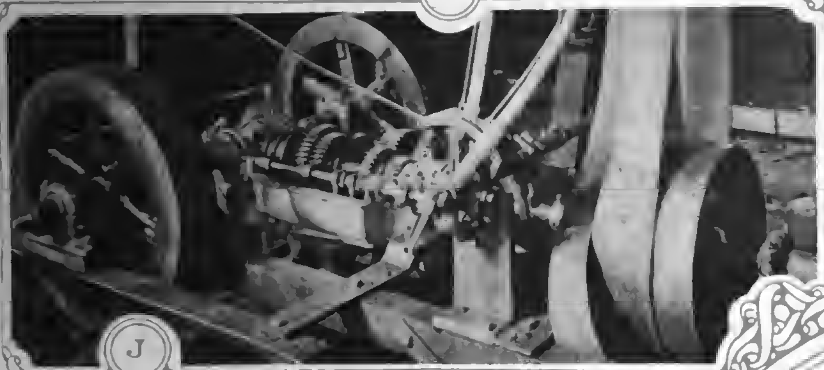
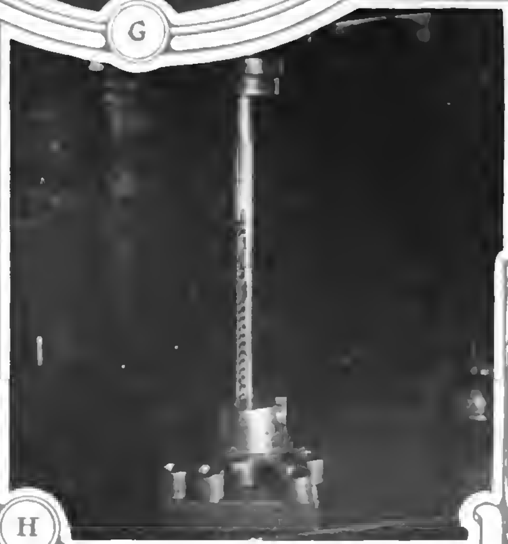
F



J

G



H

F—Hill Clark hobbing machine working on half-time gears as used on Excelsior motors.

G—A battery of gear cutters at work in the Rambler plant. In addition to the tools shown the Rambler plant is fitted out to handle the entire situation from the drop forging of the gear blanks to the gashing, planing, hardening, etc., the equipment being the most modern in all respects, including special measuring instruments which enable the inspectors to come close to the mark.

H—In the Premier plant, showing a special splining tool which is used for fashioning keyways.

I—Woods Electric transmission system, showing differential gears, one of the two sprocket pinions, tumbleshaft, and universal joints.

J—In the Thomas works, testing a transmission gear set on a special machine which was devised for the purpose of loading the gears to the maximum safe limit, permitting of the adjustment for the purpose of eliminating noise.

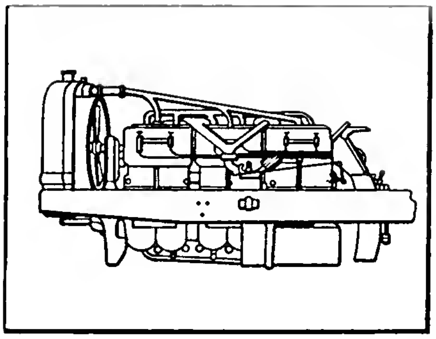
WARREN-DETROIT IS MADE IN TWO TYPES

Model 10-A is a roadster, and Model 10-B is a demi-tonneau. Excepting as to body work, tires and weight, both models will answer to common specifications. The weights, as given by the maker, are 2,000 and 2,100 pounds for the roadster and demi-tonneau respectively. The motor is rated at 26 horsepower, is a 4-cylinder, 4-cycle, water-cooled (*en bloc*) type with a bore of 4 in. and a stroke of 4 1-2 in. A vertical tube radiator is used in the cooling system and a centrifugal pump for water circulation. Ignition is by a Volta magneto, assisted by a battery and coil. In the lubrication system a self-contained pump is utilized and auxiliary splash aids in the process. A cone clutch takes the torsion of the motor and hands it to a unit three-speed (and reverse) selective sliding-gear system located just back of the motor. The drive is continued through a shaft with a single universal joint. The live rear axle is fitted with roller bearings and 32 by 3 1-2-in. pneumatic tires are used on all four wheels. The wheelbase is 110 in., tread is 56 in. and a channel section frame is the foundation for the body work. Excepting for the anti-friction bearings which take the work at all points of greatest friction, the remaining journals revolve in Parson's white metal; this metal is also used in crankshaft brasses.

It will be noticed in the detailed specifications of this car, as in the case of many other newcomers, that the features adopted are much alike. Thus, this car has a block motor, a comparatively long stroke, and self-contained lubrication. All these are featured which have been much discussed in the last year, the discussion ending with their final and universal adoption, as proof of their inherent worth.

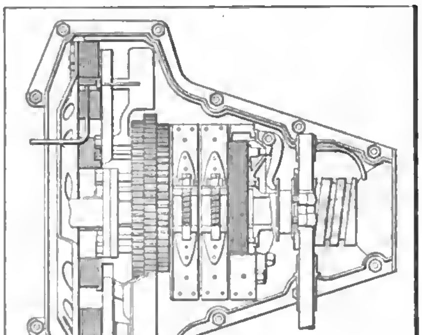
WHITE LIST EQUALLY DIVIDED--STEAM AND GASOLINE

In addition to the well-known White steamer, which is made in two models, this firm will this year make two models of gasoline cars, all four of which will be exhibited at the Chicago Show. The steamers are called O-O and M-M, while the gasoline cars will bear the alphabetical designations of G-A and G-B. The steamers are respectively a five-passenger touring model of two



View of the Winton six-cylinder, 48 horsepower motor from the left shows the position of the carbureter and the Y-shaped pipes leading therefrom across the cylinder heads to the inlet manifold on the right-hand side. The piping shown, leading to check valves on each cylinder, is for the compressed air starting device, an exclusive Winton feature which allows the crank to be carried in the tool box.

compound cylinders, double acting, and sized 2 1-2 and 4 1-4 by 3-in. stroke, and a seven-passenger, two-cylinder, double-acting compound of 3 and 5-in. bore by 4 1-2-in. stroke. The former rates at 20 horsepower and the latter at 40. Both models use the Joy type of valve gear, both have the engine located in front under the bonnet, and both utilize a flash boiler in connection with a condenser. Both models agree on the transmission, which is of the sliding type with two forward speeds, driving the rear axle by shaft, the latter having two universal joints. Engine, transmission and axles all turn on ball bearings. Turning now to the gasoline cars, these are alike with the exception of the wheelbase and the body, as well as the price. G-A has a 110-in. wheelbase and a five-passenger touring body to sell at $2,000, while

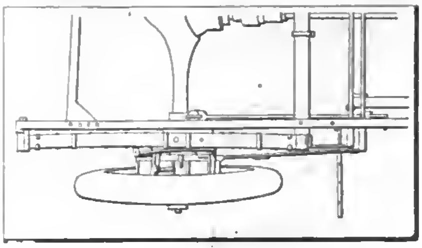


Planetary change-gear and flywheel magneto used on the Ford model T. The magneto has no commutator or brushes, no gearings, no contact points. The rotating member is a part of the flywheel. The coils in which the current is generated corresponding to the armature of an ordinary magneto, are stationary and are enclosed in the flywheel casing. The magnets, on the other hand, are on the flywheel and revolve. The electrical principle is the same, only requiring that the magnetic lines of force be cut by the armature coils.

G-B has a 120-in. wheelbase and a more roomy five-passenger body, selling at $2,500. The motor in each case is a four-cylinder unit, of 3 3-4-in. bore and a very long stroke of 5 1-8. Cylinders are cast in a block, cooling is by water, centrifugal pump circulated, ignition by Bosch magneto only, cone clutch, four-speed selective transmission rolling on ball bearings, as do also the two axles. The engine bearings, too, are ball. Other details follow standard gasoline engine practice. The power rating of this size engine is 22.5 horsepower.

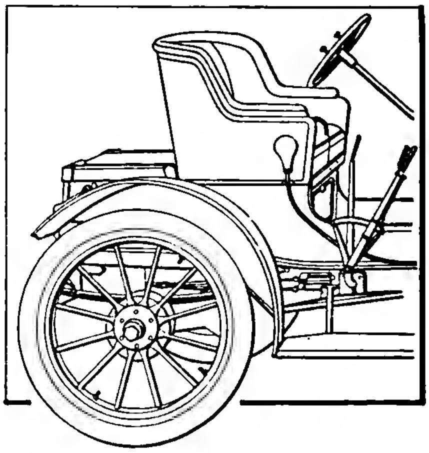
WINTON'S MODELS SIXES AND SIXES ONLY

Unless you want a six-cylinder car, you cannot have a new Winton, for the output of the Cleveland factory will be confined to a limited number of this type, in two differing powers, however. These two, both of which will be shown at the Chicago



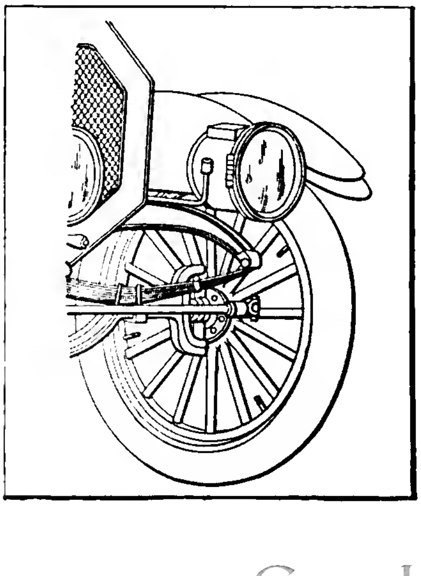
Unusual form of platform spring suspension used on the Pullman. From the external appearance of the car no one would suspect the existence of the platform spring, which is at the forward ends of the side springs, instead of at their rear ends. This makes a very neat construction.

Show, are known as Models 48 and 60, after the rated power of their engines. Except for engine sizes, wheelbase and tire sizes, the two models are nearly identical, barring, of course, the slight changes in sizes of shafts, etc., necessary to take care of the additional power to be transmitted in one case. The 48 has cylinders 4 1-2 by 5, while the large car is powered with an engine of 5-in. bore and stroke, respectively. The smaller car has a wheelbase of 124 in., which becomes 130 in. on the other. Tire equipment in one case is 34 by 4 front and 34 by 4 1-2 rear,

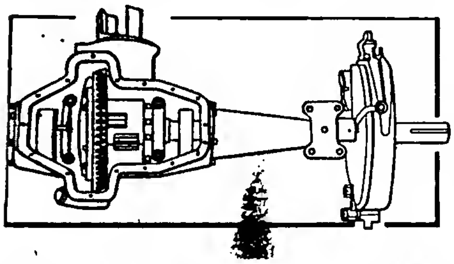


Neat body work of the new Mora 20-horsepower runabout. The large wheels and the deep seats give a comfortable appearance, and the trunk on the rear shows that thought has been given to the passengers' comfort in other ways. The car was designed to meet the requirements of the discriminating buyer who desires a small car built on smart and up-to-date lines. Control is by the standard levers, operating internal expanding brakes on the rear wheels and a two-speed progressive sliding transmission. Spark and throttle levers are on top of the steering wheel.

with option of 36 by 4 all, and 36 by 4 1-2 all in the other. Cylinders are cast in pairs, with all valves on the right-hand side, and all enclosed. The carbureter is placed on the left, and piped across to the right side, while the magneto and centrifugal water pump are both conveniently located on this same side, the right. The crankshaft is offset, and supported by four plain bearings. As always, the crankcase is split vertically along the center line, instead of the more usual horizontal split. A feature of which the makers make much, and which is worthy of close examination, is that of the self-starting device. This consists of a collector tank, which collects and stores gas under pressure from



Large wheels are becoming more and more popular, even on low-priced cars, for which it was formerly claimed that the cost of large diameter tires was prohibitive. The illustration shows a 27.2-horsepower McIntyre, which sells for $1,250. All four wheels on this car are shod with 36 by 3½ inch pneumatics. The wheels themselves are unusually robust, having sixteen spokes instead of ten or twelve. The steering knuckles are arranged to bring the center of the knuckle as near as possible above the point of contact of the wheel with the ground, to facilitate steering; this is a feature which has been much neglected of late.

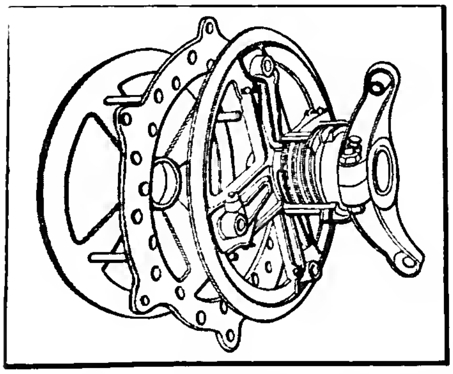


Peerless rear axle construction, showing means for allowing the camber of the rear wheels. The floating live shafts do not slip into the differential, but connect with universal joints, one on either side of the differential. Thus it is possible to incline them downwards.

cylinders one and six, during the power stroke. This is piped back to the whole six cylinders through a rotating distributor and a starting valve on the dashboard. When it is desired to start the car, pressing the starting button allows the gas access to the distributor, which permits it to flow into the cylinder, which is in the starting position. The gas drives this piston down and tbe engine starts with no manual effort by the driver.

MANY REFINEMENTS MUST BE LOOKED FOR

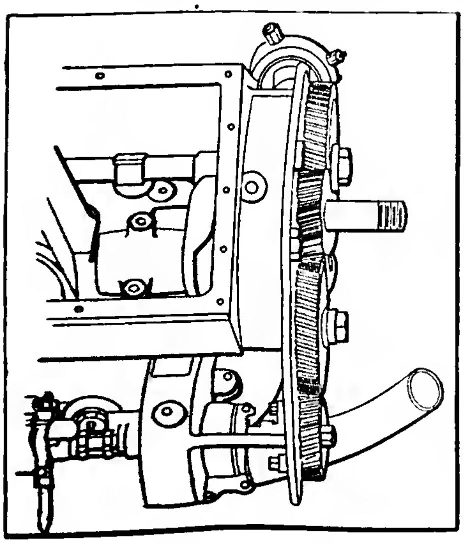
Curiosity, while it is at the bottom of many discoveries, will be beset by difficulties in its migration through the automobiles of the year, before it will be in a position to measure up



Three-plate clutch used by the Midland. The middle disc does the driving; it is mounted on studs on the rear edge of the flywheel, being made of phosphor bronze and fitted wtih cork inserts. The other two discs are of steel, floating on roller bearings on an extension of the crankshaft. They are forced into engagement with the central discs by spring pressure, applied by the medium of toggle levers. The clutch is easily adjustable and is smooth in action.

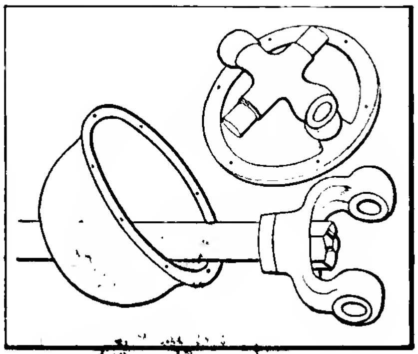
divers of the refinements which actually do obtain and which are important to the well-being of the designer, the maker, and the ultimate consumer or user.

Metallurgy, while it has done much for all industries in which steel plays an important part, was a sleeping giant before the coming of the automobile, and four or five years ago the engineers who struggled with the rickety machines which then passed currency for cars, were much perturbed when the parts after being laboriously processed, went asunder within a hundred



View from beneath of the forward portion of the Inter-State crankcase with the lower cover removed, showing the spiral timing gears. The crankshaft actuates the camshaft on one side, from which the timer shaft is in turn driven by bevel gears; on the other side the crankshaft drives the pump and magneto, which are both on the same shaft, through the medium of an idler pinion. The spiral gears are cut with little more difficulty than the ordinary spur type, and are noiseless in operation, owing to the sliding nature of the contact of their teeth. In a construction such as this they balance their own end thrust and so require no special bearing construction.

miles from home. In the haunts of steel, when the question of the kinetic qualities of materials was broached, the barefaced vendors declined absolutely to consider any further increase in quality unless as a matter of petty routine, under which conditions, should there be a sufficient incentive, a more

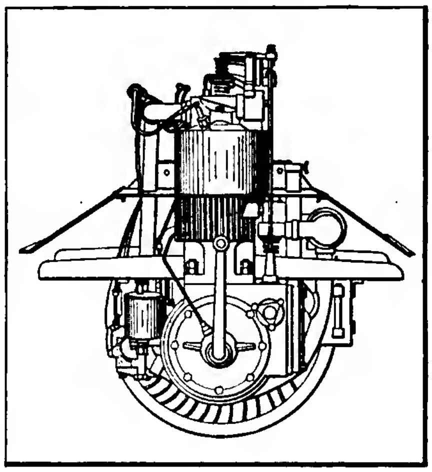


One end of the propeller shaft of the Palmer-Singer, showing the cross type of universal joint and its cover. The yoke on shaft end, the cross, the back plate, and the back plate studs which are shown holding the cross are all steel drop-forgings, the material being a chrome nickel alloy. This type of axle is ordinarily believed to require the services of a radius rod or rods and a torsion rod, which are in this case provided with much care.

promising product might be delivered, but it was pretty generally understood that there was to be no question about the additional price, the addition being very considerable.

Automobile engineers, not being satisfied with the life, considering service, of the materials which they were able to procure, delved deep into the lore of the subject, worked long and faithfully in the laboratory, argued the points with the fabricators of steel, and convinced them in the long run that what they were furnishing was as junk in comparison with the character of steel which would have to be put into automobiles, in order that they would operate sufficiently long to pay for oats.

Makers of cars are now in a position to get everything they require by way of steel, at prices which are consistent with quality, and the facilities available for fashioning parts are on a plane which is beyond the dream of the most advanced forge



Novel air-cooling system brought out by the Franklin, to insure equal cooling of each cylinder. The view shows the front end of the motor, with a section through the sheet metal hood which encloses all of the motor except the tops of the cylinders. The cylinders are shown with their sheet-metal jackets on the portions projecting above the hood; beneath this the cooling flanges, which run longitudinally, are visible. The regular Franklin concentric valves, which are continued for this year, may be discerned in the cylinder heads, and at the back is the suction-fan flywheel of a familiar type.

masters of even two or three years ago. One of the process illustrations, as given in this edition, shows a one hundred ton press, cold pressing a side bar of the most intricate shape, using alloy steel, and the operation is completed within a few minutes time, whereas in some of the earlier productions of side bars for cars, it took seven men with beatles and clamps nearly five hours to produce a single frame.

There is more in quality than will be found in the raw material which may be delivered at a plant. If the process demands several reheatings of the steel, each one of the ope[illegible] tions offers dangers, and the chances are, even with [illegible] greatest skill, that a goodly percentage of the [illegible] damaged beyond repair, under such conditions

can be raised to a definite temperature in a furnace suitably contrived, and if a pyrometer tells just what the temperature is, danger will be a remote contingency if only the press is large enough, and the entire operation can be performed without any reheating at all.

True, when a part is finished, either by pressing or in the forge, it is necessary to correct the structure, which is a matter of annealing under simple conditions, heating, quenching, and tempering under other conditions, varying the operations to suit the qualities of the materials employed and the work to be done. The plants of to-day include these facilities, they are on a basis of certainty, and they are definitely contrived for the very work which has to be performed, so that the results are equally definite, and compromise measures receive but scant, if any consideration.

Castings are now reduced to their legitimate zone of activity; they are no longer used as a substitute for forgings merely because casting methods are lower in point of first cost. This question of overhead charges is reduced to the infinitesimal increment when a large number of automobiles are built under a single roof, and the mere fact that patterns in wood may be cheaper than dies in steel, does not have to be taken into account. These castings, as they are used in the automobiles of the present time, are reduced to the level as follows:

(A) Gray iron for cylinders, pistons, crankcases, flywheels, and gearcases.

(B) Aluminum for crankcases, gearcases, and control housings.

(C) Steel castings for brackets, brake drums, clutch members, etc.

Cylinder castings, while it is admitted that they were parts which gave serious difficulties for several years, are now so readily made in many foundries, that, with just a little care, there is almost no reason why defective castings should be found in any motor. In some of the finer examples of cylinder work, castings partake of the characteristics which are not uncommon to semi-steel, and the grain is so close that under hydrostatic test of 500 pounds per square inch "spraying" is an unlooked-for contingency. This is a condition which is very different from some of the former practices, in which if a hydrostatic test was the venture none had the hardihood to extend it beyond 100 pounds per square inch as the absolute limit, and if some of the foundries were able to enforce their way at that time, it is almost certain that they would have preferred to eliminate the hydrostatic test.

This year many of the makers of cars, having tried out both aluminum and gray iron for crank and transmission cases, have evidently reached the conclusion that gray iron, all things considered, is the preferable metal to employ. There is no gain-

J—After the hair is in place, and before the follow board is adjusted in position.

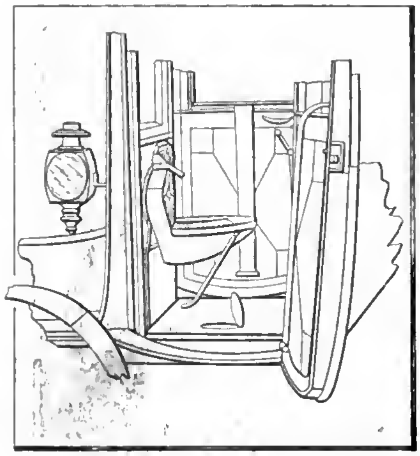
saying the fact that the gray iron is considerably heavier than the aluminum, but it is also a certainty to proclaim that it is as much stronger as it is heavier, hence the designer, if he takes advantage of his opportunity may realize a distinct advantage by employing the gray iron in many of the examples, at any rate. That this change is one of the distinct characteristics of the year, and that it has been carried to unusual length is a matter which will be readily ascertained by closely inspecting the automobiles as they will appear in the National Show.

Crankshaft work is now not only good, but the price has been sufficiently reduced by perfecting the process, so that the "toughhard" crankshafts in alloy steel do not now have to be slabbed out, and that there is a gain in favor of drop forgings, is one of the points to be made. Likewise, when reference is made to camshafts, they will stand the light of critical inspection, and it will be found that they are much improved in many ways. The new method of grinding the hardened camshafts, takes into account the presence of integral cams, and in addition to the great accuracy which is obtained, speed is so much increased that there is almost no difference in the time required between grinding a shaft when the process is impeded by the presence of cams, and grinding a round shaft of the same length.

Grinding processes have been brought into the greatest prominence, primarily, because some of the materials now used are so nearly glass-hard that they beat the cutters of ordinary characteristics, and are only managed when resort is had to high tungsten steel for the cutters, provided the work is carefully annealed. It is undoubtedly advantageous to be able to use the harder grade of steel; its kinetic qualities are on a superior basis, and the grinder is so thoroughly capable, that if there is any difference at all, it works the better if the steel is relatively hard.

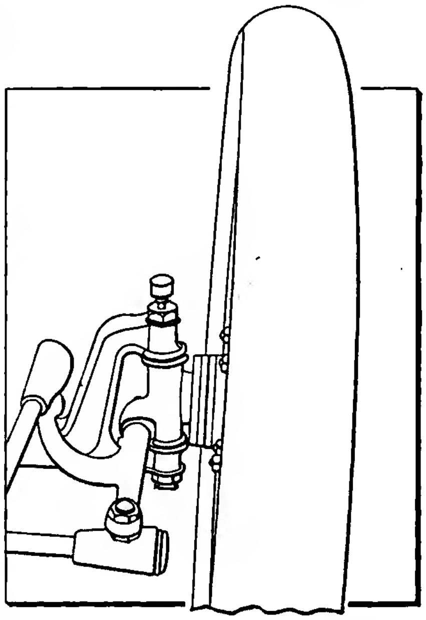
Noise, which once was looked upon as a necessary evil, is entirely absent in many cars, and as the merest suspicion in a very few. The quality of an automobile is measured to-day partly by its road work, but to a very considerable extent by its noiseless performance. Autoists instinctively reach the conclusion that beyond its disagreeable aspect, it represents undue wear, and instinct, in this case, seems to be as near right as anything can be. Noise, if it represents anything, is due to vibration, and metallurgists have long ago reached the conclusion that the life of steel oozes out in direct proportion to the vibrations, considering given fiber strain, so that the absence of noise, unless it is due to a muffling process, counts the favorable condition which comes from aborting vibration.

To some extent, noise is muffled, and it is very likely that this muffling process is one which is favorable to the life of the



View of the interior of a Rauch and Lang electric coupé, showing the small folding seat in the front, which may be utilized in an emergency. This is not a skimped seat, but of full width and depth. The car is essentially one for but two or three people, whichever the rear seat will accommodate, but it is often necessary to carry another. In just such an emergency the little refinements like this, found only on the best cars, are appreciated at their full worth. Not only are the enclosed cars the source of much thought, but equally as much gray matter is expended upon the victoria, brougham, and other open cars.

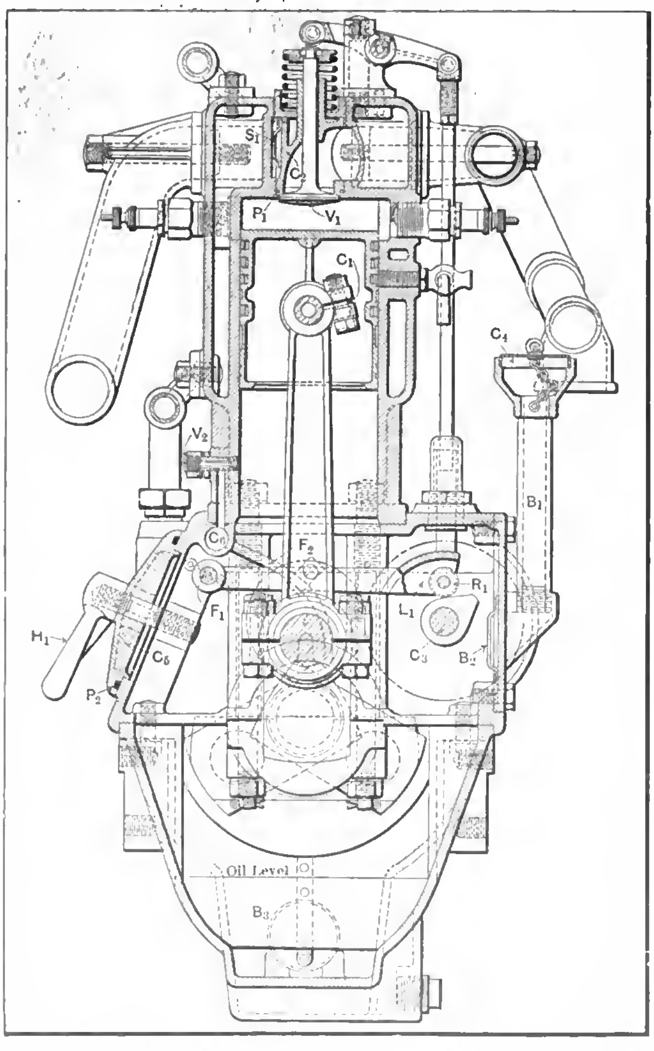
Steering pivot, connecting link, and end of cross connecting rod on the Pope-Hartford car. On this car the steering is strictly irreversible, of the worm and sector type, enclosed in a dust proof case and fitted with a 17-inch mahogany steering wheel. The steering joints are provided with spring buffers to relieve road shocks. Steering cross rods and connections are located behind the axle and are thus protected from road obstructions. The front end of the fore and aft rod is, in 1910, located above the axle, instead of underneath as formerly. The rear end is also raised, giving about three inches more clearance than on previous models. The steering column is arranged on an angle which makes the driver's position a most comfortable one. The road wheels, too, have the customary gather.



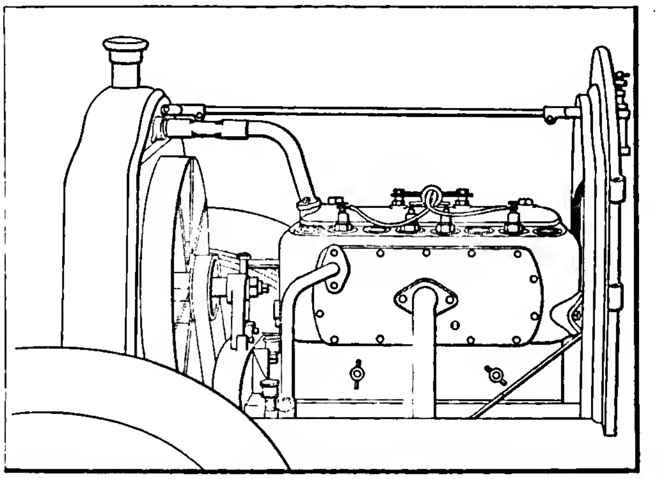
parts. Meshing gears, for illustration, if they run on the pitch line, are accurately cut, and properly lubricated, will be quite noiseless in their performance. To some extent, this noiselessness may be traced to the muffling effect of the housings which enclose the gears, and in the same way, the motors are muffled. As a matter of fact, the near presence of a suitably contrived bonnet over the power plant adds its quota in the noise-killing process, particularly if shaped with this idea in view.

It has always been especially difficult to so design the half-time gears of a motor as to eliminate noise. The cars this year seem to be well in hand in this respect. In some cases, the gears are shrouded, in others, they are of the helical cut, and in a few instances the webs are leaded. In one car (the Brush runabout) the motor is of the vertical single cylinder type and in order to eliminate secondary vibrations, a balanced gear meshes with a pinion on the crankshaft, and a relation of the balancing weight is so established that the motor is permitted to operate at a sufficiently high speed to deliver its maximum power without showing anything of the vibration which would follow under the conventional conditions of design.

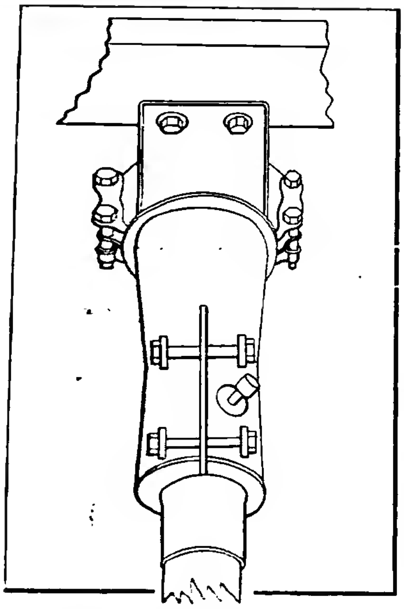
Ignition is now by magneto for the regular work in almost every automobile, and while the high-tension system obtains in the majority of cases, the fact remains that low-tension types of magnetos are employed in certain well-known makes of cars. It has always been self-evident to autoists of skill that the low-tension system is thoroughly efficient, delivers a spark with maximum energy, and is free from possible high-tension troubles, with a further advantage that the wiring system, especially those parts of it which are near the motor, is reduced to the absolute limit of simplicity, and ready removability.



Section through the engine of the Anhut car, which motor is a Brownell product, made in Rochester, N. Y. The overhead valves will be noticed as well as the operating mechanism for them. Below is seen the extension of the crankcase, which forms the oil well.

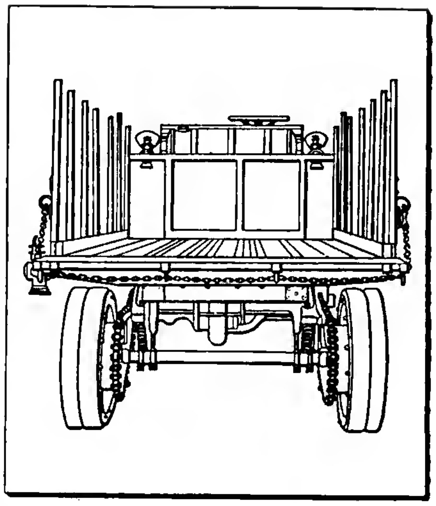


View of the engine and forward part of the chassis of the White new gasoline car. This block motor has a very long stroke, while as the cut shows, the piping for exhaust, and both water inlet and outlet is reduced to an absolute minimum.



This illustration shows the terminal of a torsion tube of a Fal car, and as will be observed, the terminal is universal in its action, of great strength, presents an adequate bearing surface, and is anchored to a substantial crossbar of the chassis frame. The torsion tube extends out from the terminal, and is bolted into intimate relation. The propeller shaft, which is enclosed, is centered on Hyatt roller bearings, is large for the work considering the character of the material used, which is selected for torsional ability. The universal action of the joint is assured by the spherical shape of the ring, which is closely fitted in a case, and the bolting to the cross member is secure. The propeller shaft is long, it is practically horizontal, and when the automobile is carrying its full complement of passengers, it is designed to afford all the advantages of a straight line drive. The transmission gear is selective.

In the Knox exhibit, while the pleasure cars will attract a wide measure of notice, it is believed that the question of commercials is now forging to the front, and the illustration here offered is of a Knox truck looking at it from the rear. This is Model 18, is rated at five tons, and the character of the workmanship is that which is characterized as fitting for this class of service. The rear traction wheels are fitted with dual solid tires. The front wheels are fitted with single solid tires and the record this truck is making is sustaining the Knox reputation in a manner highly satisfactory to the maker.

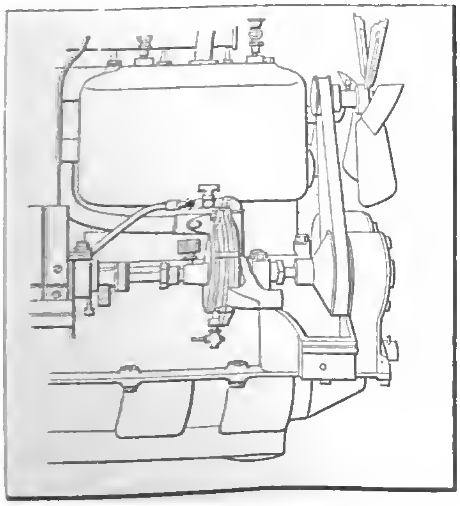


The besetting sin of the low-tension system lies in the mechanical difficulties which will confront the novice, or the half-baked artisan who fails to take into account the terrific speed with which the hammer is required to attack the anvil, and these low-tension systems, by virtue of this mechanical demand, are necessarily confined to the shops which are capable of doing this class of work. Among the cars which hold to this method are the Premier, Locomobile, Columbia, Gaeth, and others.

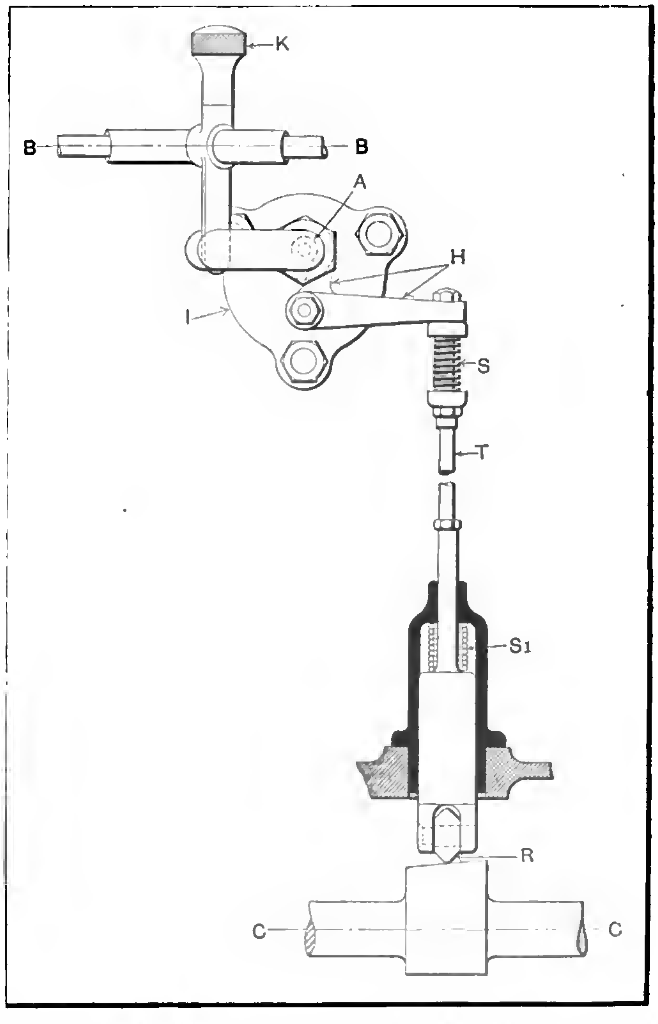
The fuel problem has been much simplified, largely because carbureters now conform to the plain requirements, and many of the auxiliary attachments which were once considered essential to success are being eliminated on the ground that while they may have been of some use, they were very troublesome by way of befogging the notions of the autoists whose mechanical inclination was severely limited.

Simplicity is present to a marked extent, all through the cars of the year, and accessibility, which was once a dream, now reaches the point where there is little to complain of.

While the low-tension systems of ignition hold their own with more or less tenacity, the fact remains that high-tension jump-spark systems are used in the majority of new cars. This high-tension work includes a magneto in almost every case, with the understanding that batteries and coils are employed in an auxiliary capacity. Uni-sparkers and other like means are frequently introduced as the main method of sparking, with the understanding that the owner of the car in such cases may have a magneto as well paying the difference. In modern coils, the energy component is on a much more substantial basis than heretofore, and the economy with which the battery energy is utilized is on a fitting basis. It is also true that storage batteries as they are now made for sparking service, are free from the old sulphating troubles, and serve extremely well for the purpose. Dry batteries, in view of their considerable capacity, low



This illustration is of the front end of the Selden motor, showing the manner in which the half-time gears are enclosed, the drive for the fan, and location of the water pump and magneto. The evidence afforded is in favor of compactness, and accessibility is one of the strong points which the company makes for this motor. The motor is rated at 36 horsepower, is of the four-cylinder, water-cooled type, works four-cycle, and ignition is on an efficient basis (see table). The cylinders are cast in pairs, are 4 3-4 x 5 inches bore and stroke, respectively, and the character of the workmanship which is put on the motor is high.



Mechanism as used on Locomobile low-tension ignition systems with a sliding cam to manipulate in adjusting the spark advance.

A—A row of motors undergoing test in the Rambler plant utilizing the new system by means of which half of the motors are driving dynamos which furnishes current to electric motors to drive the other half of the motors undergoing test on a "run-in" basis.

B—Another view of the Rambler testing equipment showing the electric motors, one for each testing block, and the tanks to the left which are placed to hold the cooling water. This view gives some idea of the vastness of the modern automobile manufacturing plant, and the problems which must be coped with. The testing room, of course, receives all of the motors at one time or another, and hence, equal provision must be made here for handling large numbers, else the motors will be poorly and insufficiently tested and run in.

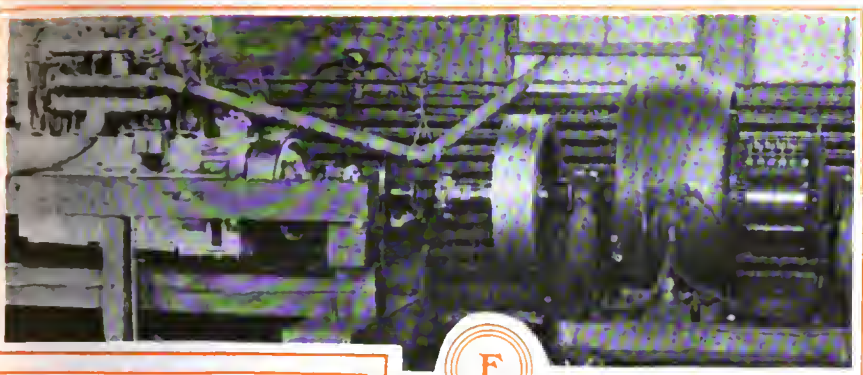
C—A static testing machine used in the Woods plant for testing the ability of flat steel as used in springs and like work.

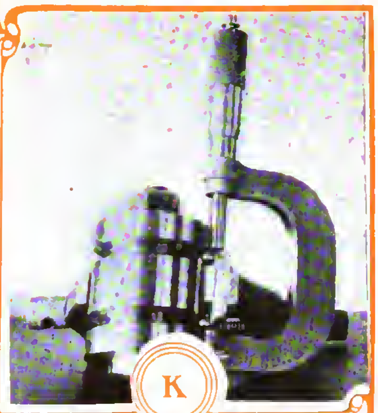
D—In the Rambler plant showing a test block with the motor to be tested removed, disclosing the tumbler shaft which connects the motor to be tested with the electric motor which is utilized in connection therewith.

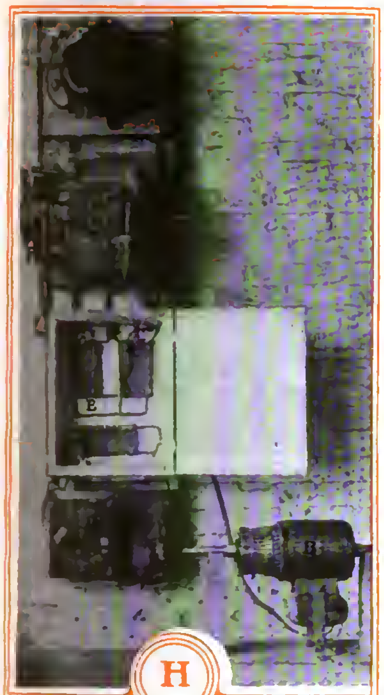
E—A view of the test room in the Premier plant showing a line of motors undergoing adjustment. Modern testing equipment provides not alone for the testing of the motor but the trying out of many other parts which enter into the complete chassis.

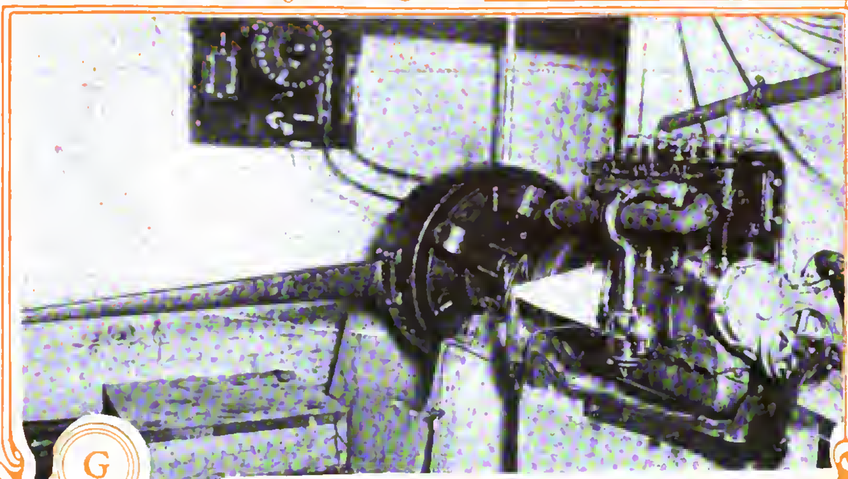
internal resistance, and a continued life without depreciation, are finding favor as the auxiliary means of supplying energy, and this is especially true when the battery box is provided with a system of terminals which will work without jarring loose, and in which the resistance of joints is at a minimum.

The question of standardization is now approaching a point where it can be seriously discussed with some expectation that the day will not be far off when an autoist will find it possible to take the wheel of any automobile and not have to learn how to manipulate the foot pedals, and sliding-gear mechanism. There must be some one right way of placing the sliding-gear mechanism so that it will serve every end, and it will be of the greatest advantage, broadly speaking, if drivers can learn once









F—An electric dynamometer as used in the Alden-Sampson plant for ascertaining the power, flexibility and endurance of truck motors of the company's design.

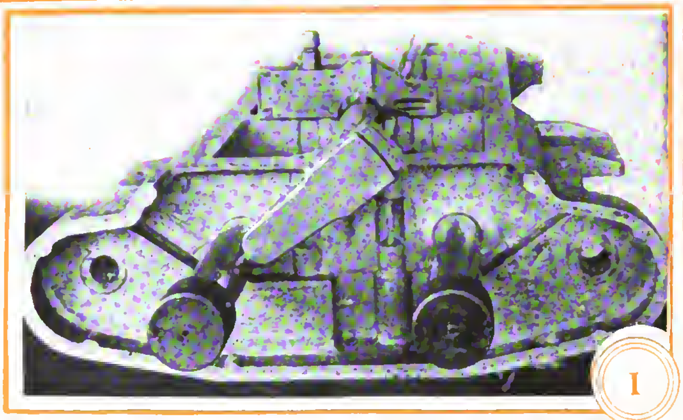
G—Electric dynamometer as used in the Inter-State plant, comprising an electrical machine with cradled fields and a lever arm which connects with platform scales. An Inter-State motor is shown on an adjacent platform ready to be tested.

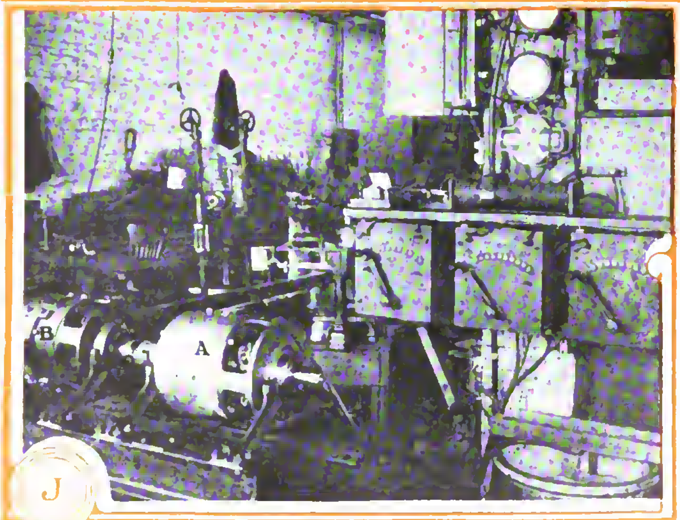
H—Electrical testing machine in the Woods plant, comprising a step-down transformer, suitable switches, volt and ampere meters, and a test block on which the armature B is placed, and by induction if any one coil in the armature is defective as to insulation, sufficient heat will be generated to cause the insulation thereof to smoke, thus disclosing to the tester the particular defective coil.

I—An instrument for ascertaining centers of the half time gear shaft in relation to the crank shaft of Thomas motors, the same consisting of a dummy shaft in place of the crank shaft, dummy shafts in place of the cam shafts and a rotating pointer which contacts with the secondary shafts equally if the work is true.

J—Testing equipment of an electrical character used in the Woods plant for determining as to the efficiency, temperature increase, commutation and endurance of motors used in Woods Electrics.

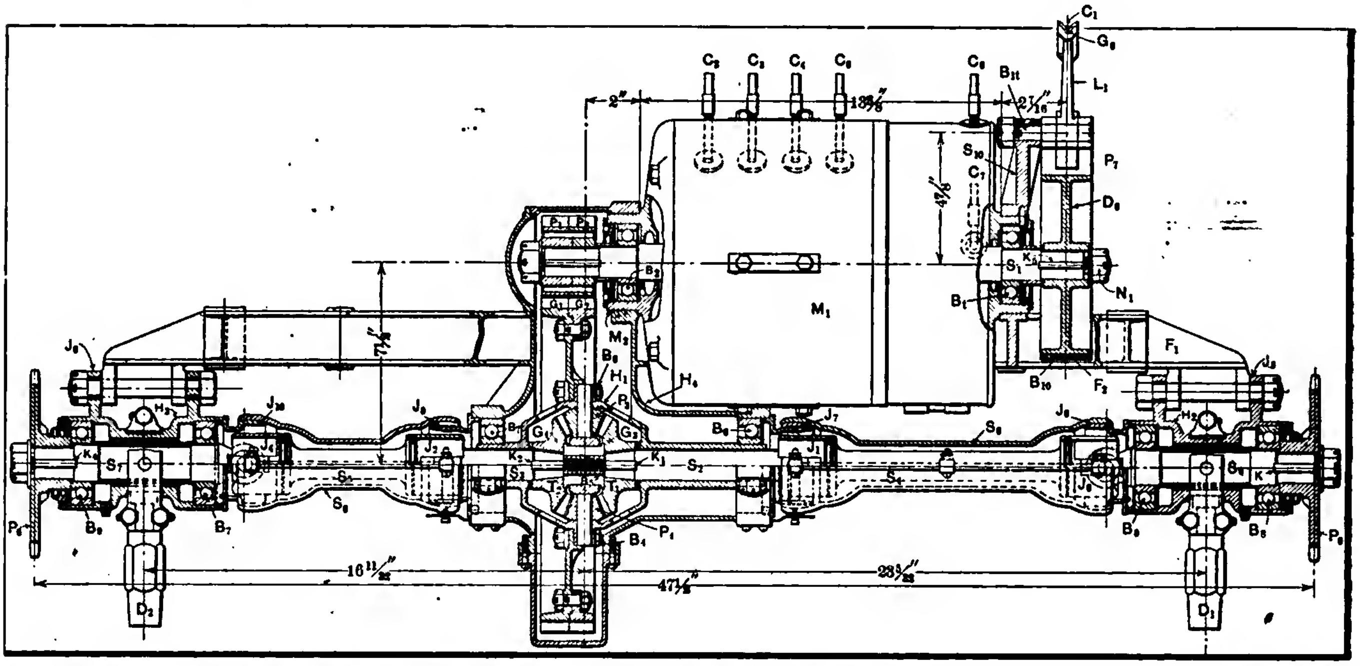
K—Measuring the center distances of the inner races of a dual ball bearing.





for all the nature of the requirement, and thereafter as a matter of habit, run a car without the dangers which are invariably present when there are no two cars alike. Skill, when it is analyzed, simmers down to the level of habit.

There are many other details in relation to automobiles which can well be reduced to a standard, and the quality, taking it as a whole, which will finally obtain, will be much higher under standard conditions, than it can be during all the period when minds disagree. It is possible to seriously consider that all the men who disagree as to the best method of performing a given test, will be more nearly right in their respective undertakings when each one of them diverges a little from the path which to him looks the most promising.



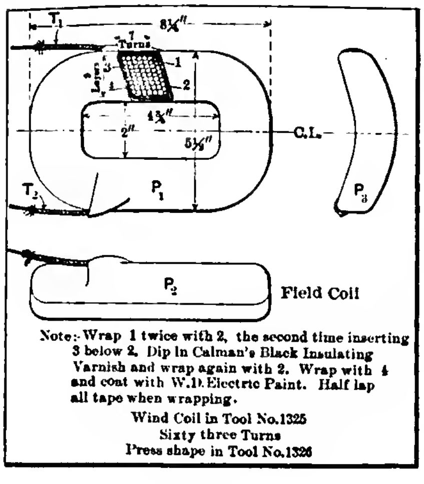
Working drawing in partial cross-section of the motor, reduction and countershaft unit of the Woods electric, showing a neat and unusual feature of design. The central case containing the differential gear is connected to the sprockets on each side by doubly-jointed shafts, preventing any possibility of binding through mis-alignment or distortion of the frame by strain from hard usage. The reduction gears are of the herringbone type, and annular ball bearings are used throughout.

ELECTRIC VEHICLES ON PARADE AT CHICAGO

INTEREST to an extent as never before centers in the electric vehicle situation, primarily, on account of the excellent service this type of vehicle has ever been capable of, and then, in view of the improvements wrought in batteries in recent times, and the many mechanical refinements which have crept into the cars. Electric motors were originally protected in connection with other modes of transportation as in trolley car service, and controllers of the drum type also emanated from the same source.

The electric motors demanded a certain amount of attention, and it took quite a little effort on the part of advanced engineers before they were as a unit on the question of the use of a single or two motors. Storage battery engineers are divided into two camps, one of which adheres to the lead type of storage battery, and the other is taken up with the Edison idea.

In the mechanical work the company offerings are diversified, as, for illustration, the Babcock Company is nailing its faith to a worm drive; Baker electrics are shaft-driven cars; Woods motor vehicle is an excellent example of side-chain drives; Detroit electric is a double reduction silent chain type; Rausch & Lang uses a side chain; Studebaker mounts the motor on davits, and a silent chain flexible drive is the result, and the Waverley is also a silent chain proposition. Each company will tell why its preference is for the particular method it employs, but the users of electrics, and spectators in general, will testify to the excellent operating qualities of electrics in general.

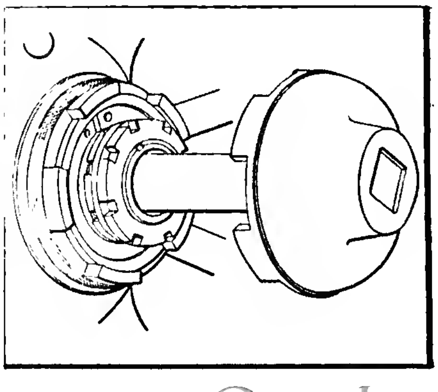


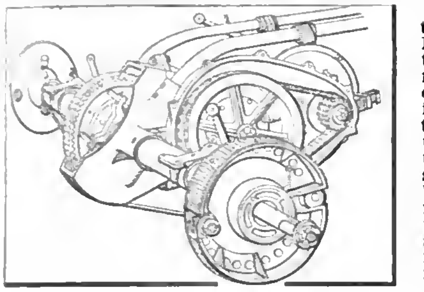
Field coil of the Woods electric, of which four are used. There are 63 turns of wire on each coil, these being wound on a form and then pressed into their final shape. Intermediate between the winding and the final pressing the coils receive four windings of insulating tape and two coats of insulating varnish and paint, to make them absolutely proof against dampness. The curving shape of the coils indicates the manner in which they are to be fitted into the frame of the motor. This is, of course, of the four-pole type, series wound, and draws its current from 40 9 MV Exide cells.

BABCOCK ELECTRIC HAS ADVANTAGE OF A WORM DRIVE

The Model No. 14, at $2,600, is a coupé for four passengers, using an individual motor, which is rated at 5 horsepower, and suspended on the chassis frame under the body, making a straight line for the propeller shaft to the housing in the live rear axle. The battery is composed of 36 cells, each with 13 plates, divided into two halves, and placed under the hood in front and under the deck at the rear. The initial reduction in the transmission system is 3.9:1, and for the rest the control system gives five forward speeds and reverse. The chassis frame

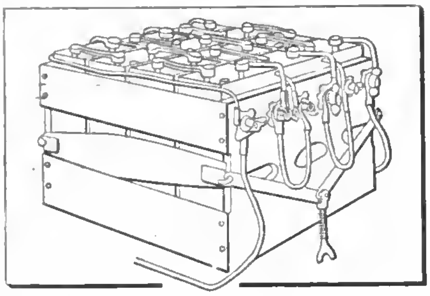
Studebaker electric uses the full floating type of rear axle, of which one of the hub ends is shown. In this drawing the floating shaft with the dog clutch on the end has been partially withdrawn from the axle, as if for removal. This reveals the five dogs on the clutch and the five sockets in the hub in which they enter to take up the drive. When the parts are in place the hub cap is screwed on over the threads. The withdrawal of the shaft reveals the bearings.





Power plant of Detroit electric models E, F, G, H and L. In this case the motor is mounted just in front of the rear axle, making a unit construction, while at the same time a large proportion of its weight is supported from the body by means of the radius rods. The motor is a multipolar, series wound, rated at 2½ horsepower under normal conditions.

Section of the Babcock battery, showing how the cells are assembled. The illustration shows twelve cells assembled in a unit for installation in the car. Connections are made from cell to cell in the same row by copper bars, permanently soldered in place to give a perfect electrical contact. The rows are connected outside the box between large and solid binding posts.



is of wood with a 3-16-inch armor of steel; annular ball bearings are used at every point, excepting for axles; Timken roller bearings are used for road wheels. The car weighs 2,600 pounds, and wheels are fitted with 32 by 4-inch pneumatics front and rear.

In addition to the worm-drive model, the company also offers its usual line, among which Models 5, 6 and 10 are notable examples. In these models a side-chain drive is utilized, the motor is swung under the chassis frame nearly in the mid-position, and the battery is divided into two parts, one of which divisions is placed over each of the axles, and the road performance as the result of this battery division is noticeably good. It has been the aim of the company in the designing of each of its models to so arrange the control that a green operator may stay green; a mistake cannot result in an accident.

DETROIT ELECTRICS WILL USE EDISON'S NEW BATTERY

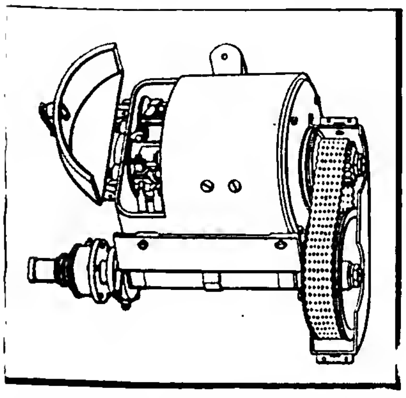
One of the reasons for the much increased popularity of the electric vehicle is the attention on the part of the manufacturers to the little details. In this respect, the makers of the Detroit Electric pleasure carriages have taken time by the forelock and announced the adoption of the newest Edison improved battery for the present season. It is claimed for this battery that it has a lessened weight for the same discharge ability, that it even has a greater discharge ability on lessened weight, which latter would mean that a vehicle with a lowered weight of batteries would run a farther distance on a single charge, that is, a lessened number of charges per season, making the whole car less bothersome as to charging. Five differing models of cars are listed as follows: H, a three-passenger roadster, of 87-in. wheelbase, 51-in. tread, driven by one 3-horsepower motor located on the rear axle, with a controller which affords five forward speeds and three reverse, with body supported upon an angle iron frame. Ball bearings are used on motor and transmission throughout the whole list of cars. On this model, the wheels and tires are 32 by 3 1-2 all around, the same as on all others. This sells at $1,650. Next in order of price comes Model A, selling at $1,900. This carries a two-passenger Victoria body, has an 80-in. wheelbase, and weighs 200 pounds more, otherwise it is the same. Above that comes Model E, a two-passenger coupé, at $2,100. This weighs 2,300 pounds. The wheelbase agrees with Model H, as do also the tires. Model C is also a coupé, but sells at $2,350. The wheelbase is shortened to 80 in., and the motor is placed in the middle of the chassis. On Model D, a four-passenger brougham at $2,500, the same description applies, except that the weight is 2,400 pounds.

BAKER ELECTRIC IS A SHAFT DRIVE

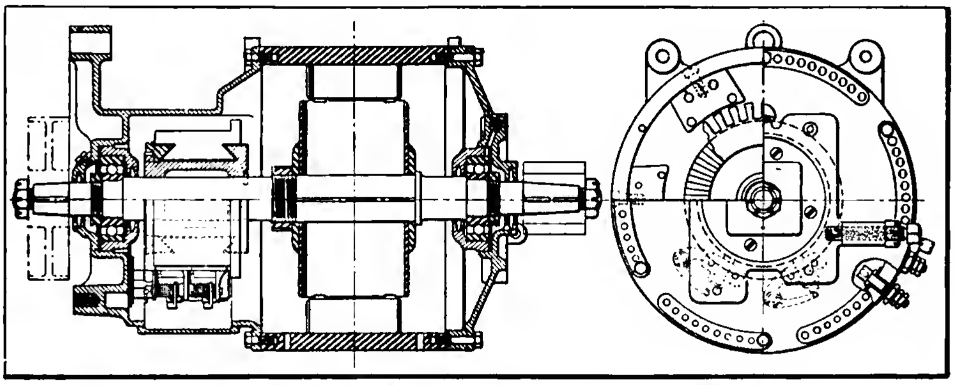
The Baker idea as it has been expounded for 1910 is with a view to conforming to the conventions as they are voiced by engineers in the automobile field in general—hence the shaft drive. Baker Electrics are made in four models, including a runabout which seats two, victoria with the same seating capacity, a coupé which seats two, and the largest size, which is also a coupé, has accommodation for four. Exide batteries are used in all Baker models, the smaller size being an 11 PV with 30 cells. This battery is divided and one-half of it is placed in the front of the vehicle and the other half to the rear. The $2,000 victoria is fitted with an Exide 9 MV battery with 28 cells in two divisions, and this type of battery is used in the remaining models as well. The transmssion in Baker models is through a silent chain to the shaft, and a live rear axle with a bevel drive serves for the rest. Ball bearings are relied upon to kill friction, and the weight of the respective models is very carefully trimmed, being 1,900 pounds for the runabout and 2,200 pounds for coupé.

FIVE RAUCH AND LANG CREATIONS WILL BE SHOWN

Chicago will see a full line of the R & L electric vehicles, which list will include no less than five stunning creations. These vary in price from the lowest to the highest, so that a car may be had suitable for every pocketbook. Beginning the list is Model 20, two-passenger Stanhope, at $1,900. This car has one 2 1-2-horsepower motor located in the middle of the chassis. Power to run the motor is furnished by 9 M V Exide cells, 24 in number, divided into several parts so as to distribute the



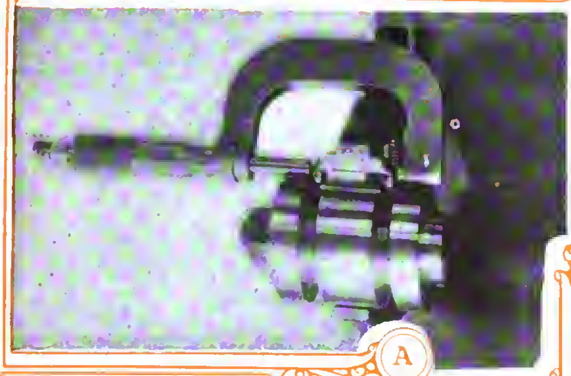
Motor, first reduction and countershaft of the Baker electric. The motor is a four-pole, series wound, and the reduction by silent chain; the propeller shaft connects on the left to the countershaft.

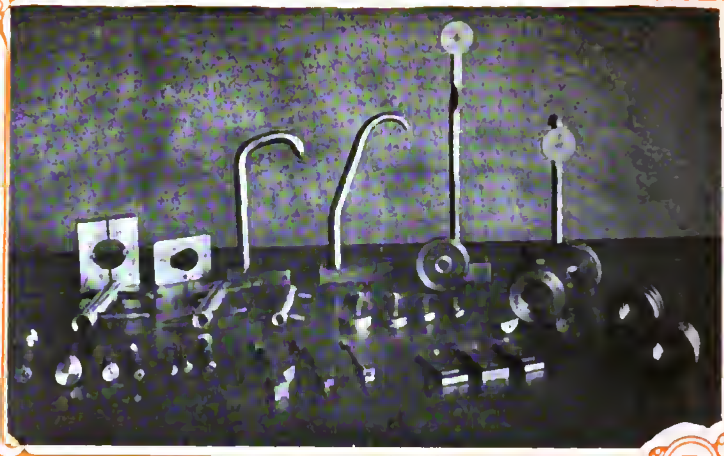


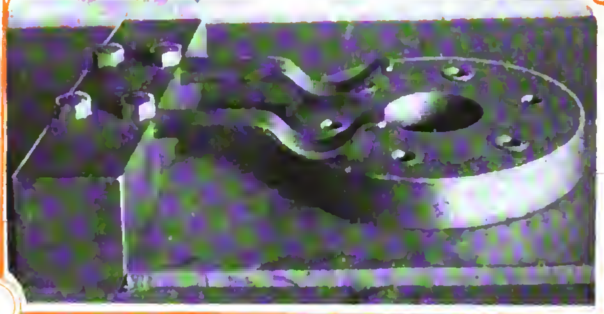
Longitudinal and lateral sections of a Waverley electric motor, for vehicle service. The field coils are indicated in their respective positions. They are altogether four in number. The armature is shown roughly, together with the means by which it is secured to the shaft, namely, a key, with a nut forcing it against a shoulder. The commutator seems wide and of proportions which will reduce sparking. The armature is mounted on ball bearings.

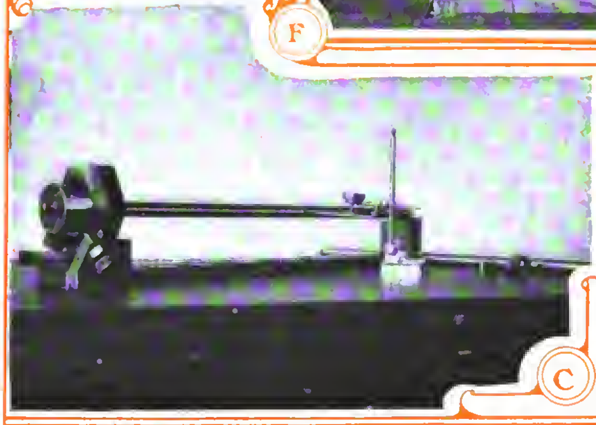
PLATE X.

Methods of Accurately Sizing









A—Micrometer measuring the center distances of inner races of a ball bearing.

B—Special measuring callipers or gauge used for sizing the walls of castings and tubes to within very close limits.

C—Extensometer fitted to a surface gauge resting on a surface plate, measuring the accuracy of the keyway in a jack-shaft.

D—Special form of tilting jig which may be set to any angle and locked in position, thus facilitating the drilling of holes which are out of the vertical or horizontal plane.

E—A collection of special measuring plug, ring, and other forms of gauges.

F—A special form of jig with accurately ground and hardened button head bushings, and a clamping means for use in reaming holes to great accuracy.

weight where it will do the most good, the same being unavoidable. The controller gives six forward speeds and three reverse, this number, like that of all electric vehicles, being far in excess of the number furnished on any other form of car than an electric. First reduction is by silent chain, while the final drive to the rear axle is by double side chains. The wheelbase is 77 in., while a tread of 53 in. is utilized. Despite a pressed steel frame, the weight ready to run is but 1,975 pounds. The tires used are 32 by 3 1-2 inches all around, and on all models except the most expensive and heaviest coupe. Ball bearings are used throughout, except in the case of the axles, which run on rollers. Model 22 is a three-passenger Stanhope, for which the makers ask $2,100. The description above applies except that the weight is increased to 2,125 pounds, and the cells used are 11 M V. On Model 133, however, the number of cells is increased to 30, this being a two-passenger runabout selling at $2,100. The wheelbase is increased to 85 inches, as is also the same quantity for all higher-priced models. The weight is slightly lessened, being 2,050 pounds. Model 23 is a very popular car. This is a four-passenger Victoria, made to sell at $2,200. Twenty-four cells are used, but the weight is increased to 2,100 pounds. Lastly, Model 24 is a four-passenger coupe and sells at $2,700. The weight is 2,550 pounds, in view of which the tires are enlarged, being 32 by 4 all around.

G—Surface gauge on the platen of a Brown & Sharpe No. 4B milling machine.

H—A depth gauge with a special terminal so made as to facilitate measuring.

I—Method of measuring the pitch of taps used in automobile manufacturing.

J—A pair of dwarfed jacks which are used in centering the work as shown.

K—A collection of instruments of precision which includes an extensometer on the right, dwarfed jacks under the socket, and a special jig to the left.

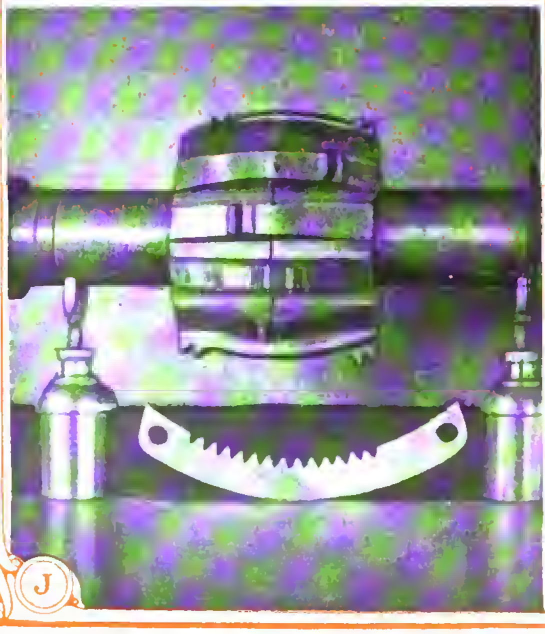
L—A set of micrometer calipers for in and outside measuring reading to thousandths.

Note—The illustrations as above given were furnished by the E. R. Thomas Motor Company, but are representative of the facilities which are used in first-class plants.

STUDEBAKER PLANS LAY STRESS ON STANDARDIZATION

With a reputation to uphold, as a branch of the company which makes the country's standard wagons and buggies, the Studebaker Automobile Company has designed a series of electric automobiles which will represent the latest development of electricity as an exact science. No type of power plant has been developed to the same degree as an electric. In gasoline and even in steam engineering practice, the designer never knows just what he will get until the first engine of a series is completed and set on the testing block. The electric motor, on the other hand, offers simply a problem in mathematics; its power can be figured with absolute accuracy while the drawings are still in the drafting room.

Thus it is not remarkable that the electric vehicles should have reached a condition of standardization far ahead of the gasoline ones. The Studebaker product, including five distinct models, varies only in the slightest details from that which bore the company's name last year. The motor, a standard design rated at 2 horsepower, though with an overload capacity of perhaps 300 per cent., is hung from the middle of the frame. It drives a short countershaft through noiseless herring-bone gears, and from the countershaft in turn a single chain drives the divided rear axle. The Studebaker Company makes five models, or differing body forms, on two distinct chassis.



A.A.A. CONTEST BOARD ANNOUNCEMENT

MEETINGS of the Contest Board of the American Automobile Association were held January 12 and 13, the following members being present: S. M. Butler, chairman; T. A. Wright, David Beecroft, Joseph H. Wood and P. D. Folwell.

The appeal of the Overland Automobile Sales Company, of Dallas, Tex., from the decision of the referee in awarding to the Mason car the first prize in the "North Texas Endurance and Good Roads Tour," held at Dallas, December 13 to 19, 1909, was submitted to the board. The appeal was overruled, and the decision of the referee affirmed, on the ground that the extreme road and weather conditions justified the referee's decision.

The appeal of Messrs. Bireley & Young, of Los Angeles, entrants of the Columbia car, from the decision of the referee in awarding the first prize to the Pennsylvania car in the fifty-mile track race held on the Arizona Fair Grounds track, Phoenix, November 11, 1909, was considered and action deferred pending the receipt of further information.

The following is a list of the proposed contests for 1910, with approximate dates, from which the Contest Board will make up its official contest schedule:

IN THE EAST

Reliability Contests

Philadelphia, Century Motor Club, ——.
Philadelphia, Quaker City M. C., April 15.
Denver to Mexico—Flag to Flag—G. A. Wahlgreen, May 1.
Hartford, Auto Club of Hartford, May 1.
Harrisburg, Motor Club of Harrisburg, May 2 to 7.
Norristown, Norristown Auto Club, May 18.
Fort Worth, Fort Worth Star-Telegram, May 22.
Detroit, Detroit Auto Dealers' Association, May 25.
National (Glidden) Tour, A. A. A., June 15-30.
Denver, Denver Motor Club, June.
New York to Seattle, M. R. Guggenheim, July 4.
Philadelphia to Wildwood, North Wildwood Auto Club, July 2.
Minneapolis-Tribune, Minneapolis Auto Club, August 1.
Munsey Tour, Frank A. Munsey Company, August 15.
Minneapolis, Minnesota State Auto Association, August 31.
Philadelphia to Wildwood, North Wildwood Auto Club, September 3.
Cleveland, Cleveland Auto Club, September.
Kansas City, Auto Club of Kansas City, September.
Louisville, Louisville Auto Club, October 8.
Chicago, Chicago Motor Club, October 15.
Denver, Denver Motor Club, October.
Worcester, Worcester Auto Club, October.

Road Races

Denver, Denver Motor Club, May 30.
Riverhead, Motor Contest Association, June 1.
Cobe, Chicago Auto Club, June 25.
Grand Rapids, Grand Rapids Auto Club, middle July.
Denver, Denver Motor Club, September 5.
Lowell, Lowell Auto Club, September 5.
Vanderbilt, Motor Cups Holding Company, October 1.
Fairmount Park, Quaker City Motor Club, October 8.
Savannah, Savannah Auto Club, ——.

Hill Climbs

Atlanta, Atlanta Journal, February 22.
Kansas City, Auto Club of Kansas City, April.
Bridgeport, Auto Club of Bridgeport, May 30.
Wilkes-Barre, Wilkes-Barre Auto Club, June 11.
Worcester, Worcester Auto Club, June 4.
Cleveland, Cleveland Auto Club, June.
Ossining, Upper Westchester Auto Club, June 18.
Plainfield, Plainfield Auto Club, July 11.
Richfield, Richfield Springs Auto Club, middle July.
Algonquin-Chicago, Chicago Motor Club, middle August.
Denver, Denver Motor Club, November.
Minneapolis, Minneapolis Auto Club, ——.
St. Paul, Auto Club of St. Paul, ——.

Track Races

New Orleans, New Orleans Auto Club, February 5 and 6.
Montgomery (Ala.) Auto Association, February 12 or April 20.
Birmingham, Birmingham Police Relief Association, April 27.
Atlanta, Atlanta Auto Association, May 5, 6 and 7.
Indianapolis Motor Speedway, May 29, 30 and 31.
Boston, Bay State Auto Association, May 30.
Brighton Beach, Motor Racing Association, May 30.
Philadelphia, Quaker City Motor Club, June 4.
Columbus, Columbus Auto Club, June 14.
Indianapolis Motor Speedway, July 1, 2 and 4.
Dallas, Dallas Auto Club, July 4.
Cheyenne (Wyo.) Motor Club, July 4.
St. Paul (Minn.), State Automobile Association, July 4.
Wildwood, Motor Club of Wildwood, July 4.
Wildwood, N. Wildwood Auto Club, July 4
Wildwood, N. Wildwood Auto Club, August 6.
Cheyenne (Wyo.) Motor Club, August 17.
Cheyenne (Wyo.) Motor Club, September 5.
Wildwood, Motor Club of Wildwood, Sept. 5.
Wildwood, North Wildwood Auto Club, September 5.
Galveston, Galveston Cotton Carnival, July.
Kansas City, Auto Club of Kansas City, July 23.
Philadelphia, Quaker City Motor Club, August 6.
Indianapolis Motor Speedway, August 12 and 13.
Indianapolis Motor Speedway, September 2, 3 and 5.
Minneapolis State Fair, Auto Clubs of Minneapolis and St. Paul, September 5 and 10.
Providence, Rhode Island Auto Club, September 9 and 10.
Indianapolis Motor Speedway, October 7 and 8.
Dallas, Dallas Auto Club, October 25.
Atlanta, Atlanta Auto Association, November 15.
New Orleans, New Orleans Auto Club, November 5 and 6.
San Antonio, San Antonio Auto Club, November 6, 9 and 13.

PACIFIC COAST

Road Races

Santa Rosa, May 9.
Portland Rose Carnival, Portland Auto Club, June 11.
Santa Monica, Licensed Motor Car Dealers' Association, Los Angeles, July 4.
Mount Baldy, September 10.
San Francisco-Portola, Auto Club of California, October 23.
Los Angeles-Phœnix, Maricopa Auto Club, November 24.

Hill Climbs

Altadena, Licensed Motor Car Dealers' Association, Los Angeles, February 22.
Mile High Hill Climb, Redlands Mile High Hill Climb Association, November 24.

Track Races

Los Angeles (Cal.) Motor Racing Association, Jan. 9, Feb. 12 and 13, Mar. 12 and 13.
Los Angeles (Cal.) Motordrome Company, April 8, 9, 10.
Los Angeles (Cal.) Motordrome Company, April 13.
Los Angeles (Cal.) Motordrome Company, April 15, 16, 17.
Los Angeles (Cal.) Motordrome Company, 24-hour, April 30, May 1.
Santa Rosa, Santa Rosa Auto Association, May 15, 16.
Los Angeles (Cal.) Motordrome Company, May 29, 30, 31.
Los Angeles (Cal.) Motordrome Company, July 2, 3, 4.
Los Angeles (Cal.) Motordrome Company, Labor Day.
Seattle, M. R. Guggenheim, September 10, 11 and 12.
Spokane, Spokane Interstate Fair, ——.

THE AUTOMOBILE CALENDAR

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.
Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main street.
Feb. 14-19........St. Louis, First Regiment Armory, Fourth Annual Automobile Show, St. Louis Automobile Manufacturers' and Dealers' Association, Robert E. Lee, Manager, 1629 Washington avenue.
Feb. 14-19........Rochester, N. Y., Convention Hall, Third Annual Show, Rochester Automobile Dealers' Association. Captain C. A. Simmons, Manager.
Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.
Feb. 10-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.
Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South street.
Feb. 19-26... ....Cleveland, Central Armory, Annual Automobile Show under auspices of the Cleveland Automobile Show Company. H. M. Adams, Secretary.
Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.
Feb. 22-26........Baltimore, Second Annual Automobile Show, Auto Club of Maryland, Fifth Regiment Armory.
Feb. 21-26........Portland, Me., Auditorium, Fifth Annual Automobile Show. F. M. Prescott, Manager.
Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.
Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.
Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Mgr.
Mar. 5-12.........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park square.
Mar. 7-12.........Albany, N. Y., Armory, Automobile Show.
Mar. 12-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.
Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsman's Show, Buffalo Launch Club. D. H. Lewis, Mgr., 760 Main St.
Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.
April 23-29.......Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

NATIONAL AUTOMOBILE SHOW FEATURES

With the opening of the doors of the Coliseum and the Armory, which will serve as an overflow, the great metropolis of the middle West will have in its midst a display of automobiles such as were never before assembled for inspection under such favorable conditions. That the show will be national in character is proven by the names which will be found on the list of exhibitors; they come from the East, the West, and the South, with not a few from the contiguous territory, which, in a geographical sense, stretches north to the frontier. The cars, which will be shown to the number of 101 separate exhibits, will be flanked by 171 accessory displays, and the slightest investigation of the situation will disclose a condition of the greatest business harmony, the entire absence of any suspicion of exclusion of any particular interest, and, in order that the ends will be met, the buying public will be afforded the fullest opportunity to examine them one and all, down to the last detail.

Comparison will be possible, and advantageous; the buyer who knows just what he wants will find it there; the prospective who is on the fence, as it were, will be able to climb down, and the maker who labored long under the delusion that he was the inventor of all that is good will find how futile it is to lock oneself up in a room, behind a stout door, with a sign on it which says, "No admittance," to dream, uninterruptedly, and to evolve, possibly, a machine which will be a world-beater.

Best of the product of brains, when all is said, is that which is presented in a photograph of the composite of all such creative powers, including in a harmonious nest, but in orderly relation, the best of all the ideas which emanate from inner man.

Just as the motor, bereft of its balance wheel, will strike a discord, due to an inharmonious beat of its cyclic relations, so, may it be said, the designer who follows his own bent, uninfluenced by the good which surrounds him, will find, when he lines up in the grand review at the national exhibition, that his ideas will scarcely hobble down the highway of prosperity without a pair of good, strong crutches to lean upon.

Taking the universe as a pattern to go by, the mind which grasps the situation, looking at it broadly, is hardly likely to reach the conclusions that things just happen; that the sun, the planets, and the stars, were merely spilled into space, and left to trickle down from level to level, the plaything of circumstances, and as vagrants of a thoughtless child, ricochet as they travel, wearing to a threadbare suspicion of the mass of inception. So it is with the handiwork of thought when it is blended into a tangible thing by action; the thing will be representative of the thought, which, if it is the product of a finite mind, will scarcely compare with the more imposing array which will follow a concert of action, as when minds agree, and the product becomes the offspring of a pyramid of harmonious thoughts.

A national show—at which are gathered the products of a year of effort—is bound to result in the greatest good to the greatest number, since, when comparison is made under conditions of equality, the points of merit will come to the surface, and the things which are not worthy to survive will be roundly condemned by all.

In making comparison, the point of view must not be lost sight of; the automobile which will serve as a plaything for the idler who is struggling to lessen income is not likely to prove of great utility to the man who mortgages his homestead to acquire luxury on wheels, nor can it be said that a homely "draught horse" of an automobile will gracefully support the "family crest." To go to the show dressed in the right mind is to remember that every type of automobile has as a mate a user who will be well satisfied if envy is not allowed to cast a blur over the eyes, and in the moment of confusion substitute a white elephant for a pleasing companion.

Let the salesman rant of his wares; he is paid a stipend to do so, just as a lawyer is retained to defend a "case" —it may be one of little standing in law when the truth is bared. Go to the show, purchase with real money rather than with the exchange of a mortgage, and select the automobile which will do the very work for which it is intended, or, better yet, consider well the work to be done, and select the very automobile which is designed to above everything else thrive in that very class of service.

CONFLICTING STATEMENTS HAVE BEEN CIRCULATED

CHARLES Y. KNIGHT GIVES OUT THE ACTUAL FACTS

ABOUT THE KNIGHT MOTOR IN UNITED STATES AND ABROAD

NEW YORK CITY, Feb. 3—So many conflicting statements have been circulated in this country regarding the Knight motor in the United States, that I deem it advisable, in justice to the owners of the patents as well as to the public, to make a clear statement of the situation, and have also been requested to include some review of conditions abroad.

At present there are five licensees in Europe under the Knight patents, viz.: The Daimler Company, Ltd., of Coventry, England; Messrs. Panhard & Levassor, of Paris, France; the Daimler Motoren Gesselschaft (Mercedes Co.), Unterturkheim, Germany; Minerva Motor Company, Antwerp, Belgium, and the Deluca Daimler Company, Ltd., of Naples, Italy. We issue only one license for each European country, and there are three unimportant states where we have yet to license anybody.

The Daimler Motor Company, Ltd., of England, took this motor up in December, 1907, and began delivering cars equipped therewith in December, 1908, putting out about 800 large cars during the season ending September 30, 1909. Aside from these cars of the 1909 type, they replaced nearly 100 of their 1908 poppet valve motors with the Knight motor for customers, and sold a number to go abroad to other motor car companies. They have not built a single motor of the poppet valve type since taking up the Knight motor, and are employing it in their omnibus and railroad car work. Their output for 1909 comprised motors of the following dimensions and R. A. C. rated powers

H.P.	Dimensions	No. Cyl.
38	4⅞ x 5⅛	4
57	4⅞ x 5⅛	6
48	5½ x 6	4
22	3¾ x 5⅛	4

For the first two months of the 1910 season this firm's sales exceeded the output for the entire 1908-1909 season by quite a number of cars. This company won the Royal Automobile Club's Dewar Trophy for the best certified performance of the year with two motors (38 and 22 horsepower), which ran for six days and nights continuously under full power, the 38 horsepower averaging nearly 55 horsepower at 1,200 per minute, and the 22 averaging more than 38 horsepower at 1,400, and then these motors were placed in standard cars and run 2,000 miles on Brooklands, at the rate of 42 miles per hour, without a single mechanical hitch.

Daimler cars also won numerous hill climbs in England during the year, and were the first English built cars to sell in any number in France.

The next to get ahead with these motors was the Minerva Company, of Belgium, who took the work up about six months later than Daimler and only managed to get in with a few 38-horsepower four-cylinder cars in 1909. These were built with 20 per cent. offset of the crankshaft, were very fast, and one in the hands of their Glasgow agents won the Scottish Cup for lowest fuel consumption in the Scottish trials last summer, against 68 competitors from all over the world, covering 1,000 miles at an average of 24.96 miles per imperial gallon of petrol, and making fastest combined time on the hills and mountains of the course, both as to actual time and under formula, and winning medal therefor. In two miles the consumption worked out 45 to the gallon and was 10 per cent. better than any other car has done in these drastic trials.

For the season of 1910 the Minerva Company is making no poppet valve motors whatever, producing the Knight motor in three sizes—16, 26 and 38 horsepower, four cylinders. Their entire 1910 product was sold previous to October 1, 1909, among the various countries of Europe. Their 38 horsepower during 1909 won many hill climbs and races on the continent and in England. in addition to the Scottish Trials victory.

Panhard & Levassor will be delivering cars equipped with Knight motors in May or June of this year. Their first demonstrating car was sent to their London agents in December and was equipped with a four-cylinder motor, dimensions 4 by 5 1-2, which under test developed 43 horsepower at 1,140 revolutions. This company will not produce a great many cars of this type during 1910, owing to the lack of preparation and proper tools, having subjected the motor to 15 months of the most severe tests which could be devised before finally adopting it. One agent alone has guaranteed to contract for the entire 1910 output of cars equipped with this motor at a premium of $300 per car over the same chassis with the poppet valve motor.

The Mercedes Company will not get into the market until late in the Fall, this company being the last in Europe to take up the motor. Machine work will begin upon parts in May and cars will probably be ready for Fall delivery. Their motors have given splendid results under test, the 38-horsepower four-cylinder (4 7-8 x 5 7-8) showing 61 horsepower at 1,300 and the 22-horsepower (3 3-4 x 5 1-8) 50 horsepower at 2,000 revolutions.

No. of Revolutions per minute	Knight Motor 4 cylinders 3 3-4 x 5 In.	B.H.P. of 6-cylinder Engine, 4 x 4 3-4-In. Poppet Valves
400	12	12.1
500	16	16.6
600	21	20.8
700	25	24.8
800	29	23.4
900	33	32
1,000	37	34.6
1,100	40.5	37.4
1,200	45	39.3
1,300	48	41.8
1,400	51	43.6
1,500	54	45.2
1,600	56.5	46.5
1,700	58.5	47.5
1,800	61.25	48.2

The Deluca Daimler at Naples will not be in the field until late in 1910.

In America we have made no great effort to start going. The industry has been booming to such an extent that the manufacturers have been reluctant to make a start upon a new program, and we have been too busy abroad superintending the introduc- of our motor over there to permit us to devote a great deal of attention to this large field. In Canada the Canada Cycle & Motor Company have acquired the rights for use in the Russell car, E. L. Russell, the manager, having come across to England during the summer of 1909 to make the arrangements. They are now putting out cars of their own construction equipped with 22 and 38-horsepower Daimler (English) and Minerva (Belgian) motors and have been very successful. Some idea of the interest aroused by the appearance of these motors in Canada may be gathered from the fact that more than 1,300 people last week attended a meeting held under the auspices of the Engineering Society of the Faculty of Applied Science of the Toronto University upon the occasion of an address by the inventor relating to features of the motor.

The tendency so far as our own business is concerned is toward a stroke of about 5 inches regardless of bore, and there is no doubt an inclination in Europe toward a stroke at least 25 per cent longer than the bore, up to 6 inches. The entire English and European industry look askance at the colossal concerns upon this side, fearing a flood of cheap cars to the other side when the pendulum finally swings to the other extreme, or when what they regard to be the inevitable reaction comes.

(Signed) CHARLES Y. KNIGHT.

MAXWELL-BRISCOE, COLUMBIA, BRUSH RUNABOUT MERGER

UNITED STATES MOTOR COMPANY RAPIDLY CRYSTALLIZING

SIXTEEN-MILLION-DOLLAR AGGREGATION OF MOTOR INTERESTS

BENJAMIN BRISCOE, having just returned from Detroit, where a conference was held with Frank Briscoe, President of the Brush Runabout Company, and the Briscoe Mfg. Company, carried in his wake a series of persistent rumors which have for their purport much more definite matter involving the future of the United States Motor Company, than that which passed current in recent days. The best information available at this time is to the effect that the Maxwell-Briscoe, Columbia, Brush Runabout, Briscoe Mfg. Company, Ajax-Grieb Rubber Company, Westchester Appliance Company, and other concerns of a representative character, are the moving spirits in this monster re-arrangement of automobile interests. To what extent this nucleus will gather force is a matter which will have to be confined to speculation. The character of the men and the companies represented in this new line-np is such as to whet the imagination, and it is anticipated by the knowing ones in the inner circle, that the United States Motor Company is destined to rival the Napoleonic movements of the most ambitious efforts in recent times; it being the idea, according to reports, to coalesce a series of companies, each one of which is to be a leader in its particular line of endeavor, financially self-sustaining, and so situated with respect to the market that the united concerns will add their respective quota without overlapping. In this way, it will be possible to reap advantages in all directions, because each unit in the big combination will be habitually expert in its own particular line, and the sum of these units will be of concentrated advantage, due to the combined ability under conditions of economy of management, which should result in the greatest good to the purchasing public, taking the form of superior product at the minimum cost.

It has long been understood by those who keep informed as to the strength of the undercurrent in automobile circles, that the General Motors Company had its eye on the Maxwell-Briscoe series of plants, which it hoped to augment by taking over the big new plant in which Brush runabouts are made. Frank Briscoe seems to have been adamant in the face of all these tempting offers, and perhaps the present proposed creation represents the gist of the real answer; at all events the market has evidently suspected something from the quarter which is dominated by the Maxwell-Briscoe interests, and the activities of the General Motors Company in the direction of acquiring these interests led to speculation of the groundless sort.

The market was merely blinded by the known fact that the General Motors Company wanted to make a combination, and while rumor mongers basked in the light of this one idea, the real scene was being shifted into presentable shape behind an asbestos curtain.

The United States Motor Car Company was quietly incorporated under the laws of the State of New Jersey, and the capitalization was stated to be $2,000, which inconspicuous sum lent an air of mystery to the project when it was learned that the Maxwell-Briscoe string of capital had its finger in the pie. C. W. Kelsey, of the Maxwell-Briscoe Company (head of the sales organization), is arranging to take up his new duties in Hartford, and the old Columbia Motor Car Company is bound to feel the energizing presence of Kelsey, as soon as he is able to find a suitable residence for himself and family, which, however should not be an extremely difficult task in Hartford.

That it is considered a move of the greatest importance for the United States Motor Car Company to acquire the Columbia Company is readily seen when the point is made that the Columbia Company, under the skillful management of the late George H. Day, secured control of the Selden patent, and this company has always represented the dominant situation in the management of the Selden patent. When the Maxwell-Briscoe Company, Premier, and five or six others, came down the A. M. C. M. A. tree, it was little thought that by a skillful move on the part of the Maxwell-Briscoe interests, they would climb to a more favorable position on the other tree which the Court put its mark of favor on. Around Hartford, the situation seems to be fairly well understood, and the automobile fraternity there is aroused to a high pitch of anticipating excitement.

There are quite a number of side lights to be attached to the latest move, as, for illustration, the string of capital which controls the destinies of some well-known Philadelphia electrical companies (one in particular) is said to be allied with the Maxwell-Briscoe line-up. This should not be surprising since the connection which has ever existed between Philadelphia capital and the Columbia Company would still have to be taken into account.

A.M.C.M.A. TO BE DISBANDED AT CHICAGO

While it is true that the controlling factors in the A. M. C. M. A. will not disclose beforehand the action which will be taken at the meeting which will be held in Chicago during the National Show time, it is fairly good inside information that the A. M. C. M. A. is to be abandoned. It was originally organized under a contract for five years, and the time will expire within the next week or two. That this contract will not be renewed is largely due to the absence of companies outside of the A. L. A. M. When the atmosphere clears up, the only company left will be the Ford Motor Company, and while it seems quite certain that the Ford will continue as heretofore, the fact remains that the A. M. C. M. A. was organized almost independently of the position which was previously assumed by Henry Ford. He is still sticking to his position as then taken, and the disbanding of the A. M. C. M. A. is simply a logical move in the absence of members to support it. An association without members is in a rather anomalous position.

ALL BUT FORD TO BREAK INTO A.L.A.M.

It is now fairly understood that all the companies which were joined together under a contract for five years, and were known as the A. M. C. M. A. will be admitted into the fold under terms which The Automobile published some time since, but it was not then assured that the entire list of A. M. C. M. A. would come over. While the association is acting upon these names, seemingly one at a time, the fact remains that there is a place, apparently, for each one of the A. M. C. M. A. companies, with the understanding, of course, it desires a seat at the board.

RUSHMORE AND DIETZ LAMP FIRMS MERGE

It is announced that the Rushmore Dynamo Works, of Plainfield, N. J., and the R. E. Dietz Co., of New York City, have effected a combination to promote the sale of Rushmore lights and generators and Dietz oil lamps. Numerous improvements will be made, and the factory facilities greatly increased.

Whitney Mfg. Co., Hartford, Conn.

Accessory Display

GRANTING that the automobiles will all be lined up at the Ninth Annual Exhibition at the Coliseum and the Armory, all is not said. Separating out the accessories, in order that they may be the more conveniently examined, is all that it amounts to—the very cars which present such a fine spectacle, are only so because they are graced by the very accessories of which they are largely composed. Considering the accessories then, taking them away from the automobiles on which they rightfully belong, is but a convenience.

These units of automobiles, when they are properly considered, may well be separated out into classes, and in the process, to accept one of two or three schemes is a necessity. Trade considerations are at the bottom of some of the methods of classifying; tires, for illustration, are scarcely accessories—automobiles, to be of any use at all, must be equipped with them. In the long run, if the question is to receive intelligent treatment, the autoist who desires to advance on a firm footing, must remember:

(A) So-called accessories, provided they must be a part of an automobile if it is to run at all, belong to a class here designated as "units."

(B) Accessories, which are not essential to the running of a car, but, on the other hand, are present on a car if law and safety are given due weight, become accessories of necessity.

(C) The remaining consideration involves accessories of convenience—accessories which can be done without considering the running of the automobile, or the law, and safety.

Parts makers, as a rule, manufacture, from submitted designs, parts of units, and, from a logical point of view, belong to another class, or better yet, are as an annex of the automobile makers who employ them. Unit makers, since they evolve designs, have in mind the furtherance of their own interest, insofar as the establishing of a reputation for turning out good units becomes as a stock in trade which is ordinarily designated as "good will."

Accessories of necessity, under the classification here suggested, will be a little difficult to separate out; speedometers, according to some are not necessary; judging speed, on the other hand, is exceedingly difficult, and the autoist who regards the law, must admit that it is necessary to know the speed which is being made at any time in order to keep within the law. Take the ignition system, as an illustration of the difficulty involved in making a logical classification, and it is at once apparent that the magneto is a necessity, but it cannot be so readily shown that the auxiliary coil and battery is entitled to this rank—the coil is used when the magneto fails; true, under such conditions the coil will become a necessity, but this truth ranks with the conclusion which must be reached if the whole motor becomes deranged—another motor will have to be supplied.

Lamps are accessories of necessity when automobiles are run in the night time—they are merely onaments in broad daylight; the necessities rule, however, in making the classification. When the whole situation is adequately explored, it is difficult to separate out the accessories of convenience; perhaps a foot-warmer is in this class; mayhap a grademeter responds to the name, and it is convenient to have a time-piece on the dash, or a guidebook in the locker, a place for extra wraps, room for a trunk, and a windshield to break the force of the on-coming blast—let it be dust, wind, or the pesky messenger of the elements which takes on the form of hail, not forgetting a swarm of gnats.

WIDE AND VARIED

It is convenient, of course, to have a pair of goggles—are they necessary? Some times! Tops, for touring cars; they are as the "umbrella." Chains, for wheels; they prevent skidding. Extra tires—not so necessary these days when tires of good selections, and large enough for the work, are in common use—they are as a safeguard. If extra tires are taken along, why abuse them by allowing strong light, the product of inclement weather, and silt of the road to perch upon them—tire life is measured by two kinds of instruments, one of which is called "long" and the other "short." The particular one of these measuring instruments—instruments of precision, let us say, to take along, will depend upon the quality of the casing which hides the tires.

Lubricating oil is the "diplomat" of the automobile; it is as the go-between when friction and the "chip" which is on the shoulder of a journal begin to rub elbows. A can of lubricating oil is mighty handy; a convenience, let us admit, which has necessity as a first cousin. Grease! it is the diplomat's secretary. This same grease, in its capacity of secretary, does the dirty work; stands as a buffer between the silt of the road and the delicate surfaces of the plurality of bearings which are not provided with a drawing room in which to ceremoniously receive the prince of lubricants—oil.

The know-it-all who is so fond of saying that grease is out of a job until a journal warms up, ignores the fact that oil is not necessary in a bearing which will not warm up—let us have the can of solid lubricant; some of it belongs in the transmission gear system, more in the steering gear, a little in the eyes of the springs, a smear over the knuckle-pin, and a little here and there; with a portion in reserve.

Shock absorbers, while they are regarded as accessory features of automobiles, are so necessary that the automobile which speeds without them is far on the road to the guillotine; they soften the blow which comes when an obstruction rises up out of the roadway, and afford a second advantage—riding has more of pleasure, a better assurance of a safe ending, and less of the thought that the score will draw heavily upon the bank account. The need of shock absorbers, while it is absolute if the spring suspension is but poorly designed, is also present in proportion to the weight of the automobile and as the square of the velocity.

In the maintenance of tires, considering the composition of them, which is frictioned fabric in alternate layers with rubber, to measure life on the long scale, there are two or three details which must not be disregarded—the tires must be stoutly inflated and maintained in this state at all times. Besides inflating, in view of the ills which follow if dampness contacts with the bared fabric, it is essential to success that the fabric be kept coated with rubber. To assure this condition, it is necessary to repair each little score just when it happens; the fabric being cotton, serves as a wick, and the water which will be drawn in, is sure to carry along a myriad of mildew microbes.

It is useless to smear cut rubber over a wound—the rubber must be vulcanized; a vulcanizer is the accessory which will do the work quickly and well. As for inflation, it has been stated by experts of undoubted competence, that the autoist is not living who will be able to inflate a 36 by 5-inch tire to excess by using any manual tire pump made. The danger lies in not inflating sufficiently, and, without a gauge to tell of the growing pressure, it is very easy to allow the tired muscles of the man to act as the gauge—a tired man is a mighty poor gauge when it comes to the matter of coaxing long life out of a tire.

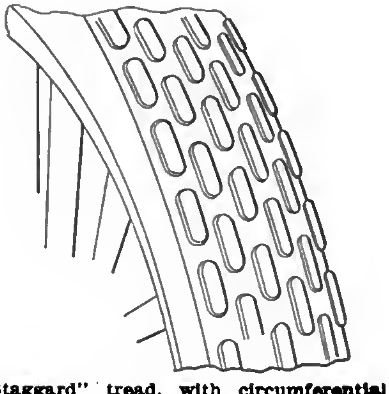
No label is needed on the Firestone non-skid, which has its name printed on it some thirty times, and leaves its mark as it goes.

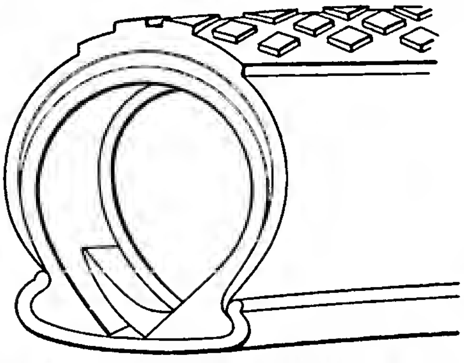
TIRES RIMS AND CHAINS



"Staggard" tread, with circumferential rows of oblong projections, characteristic of the Republic, non-skidding tire.

SOLUTIONS of the tire problem are many and various, and although grumblers may say that it is not really solved yet, still the situation has been reduced to a point where tires are fairly reliable and can be expected to give a known amount of service. Non-skid treads are especially in evidence, and the forms of demountable and quick-detachable rims show evidence of great inventive skill having been expended on them.

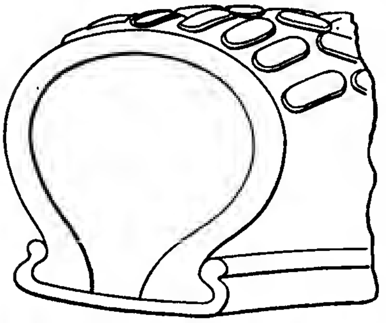
The latest production of the Ajax-Grieb Company, of New York City, following out the lines indicated above, is a diamond tread non-skid tire. The tread is simply made about 1-8-inch thicker than usual, and then criss-crossed with diagonal grooves. The raised diamonds thus resulting are so designed as not to flatten into a smooth surface when bearing the weight of the car, as they might be supposed to do. Of course, all Ajax tires will continue to be guaranteed for 5,000 miles, according to the well-known plan.



Diamond-shaped projections, arising from an already thickened tread, distinguish the Empire, new anti-skid tire.

The Continental demountable rim, marketed by the Continental Caoutchouc Company, of New York City, is one of the automobilist's old stand-bys. It shows few changes over the 1909 form. The clincher rim on the inner side bears against a permanent flange, and on the outer is retained by a series of wedge-shaped lugs on bolts which pass through the felloe. Lugs on the under side of the clincher rim rest in notches in the felloe rim, so preventing rotation. Continental non-skids are also shown.

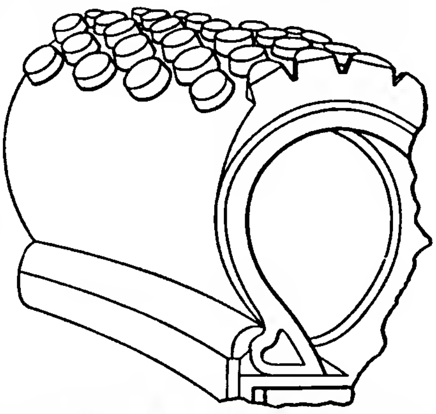
Dayton airless tires are again shown without change, except in that different styles of treads are offered to the purchaser. One of these, which the company calls a double-grip non-skid, has a flat corrugated tread with diagonal depressions about an inch apart. The interior construction of the Dayton is already familiar, the inner tube being simply abolished and the outer shoe strengthened with crosswise ribs molded integral. The maker is the Dayton Rubber Mfg. Co., of Dayton, O.



Morgan & Wright has oblong projections arranged in two spiral series, alternating with each other.

The Diamond Rubber Company, of Akron, O., shows that it fully appreciates the possibilities of the solid tire on motor buggies and commercial vehicles by showing a complete line of these, in addition to its well-known pneumatics. A new demountable rim also appears under the Diamond banner; it is of the bolt-retained type and looks solid and substantial. Several varieties of anti-skid treads also are shown at this stand. This company also manufactures hard rubber steering wheels and battery boxes.

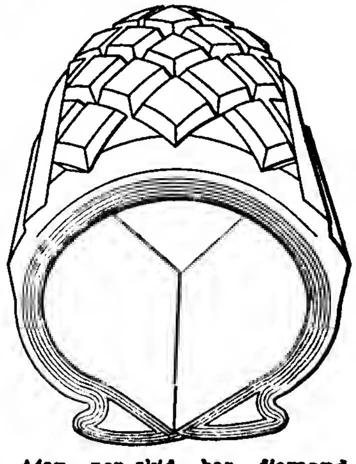
The checkered tread tire which appears at the stand of the Empire Tire Company, Trenton, N. J., is another variation of the groove idea; in it, however, the diamonds stand out separately on a raised portion of the tread. The Empire demountable rim is of the bolt-retained type; it is not necessary to remove the nuts on these, but merely to loosen them. The lugs may then be turned aside and the rim slipped off over them. This does away with the annoyance of losing these small parts in the road dust or mud.



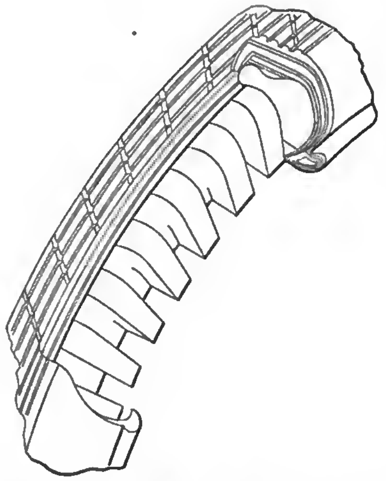
The time-tried Bailey tread is retained on the Diamond, and gives satisfactory service, both summer and winter.

The Federal non-skid, brought out by the Federal Rubber Company, of Milwaukee, Wis., has an idea apparently unique among the supporters of the all-rubber tread. These tires, known as the "cross-country type," have around their circumferences three rows of maltese crosses molded in the rubber. The rows are staggered with relation to each other, and the great number of sharp points seems well adapted to give a thoroughly firm grip on the road, even under the worst conditions.

No one could mistake the Firestone non-skid, no matter how unlearned he might be in technical matters; for it has its name written across it in bold letters some twenty or more times. The Firestone Tire & Rubber Company, which is another of the Akron group, believes in the all-rubber tread. The Firestone demountable rim, of the through-bolt type, differs from the ordinary run in that it is adapted to carry clincher rims of the



Ajax non-skid has diamond-shaped projections, formed by cutting grooves in the tread.

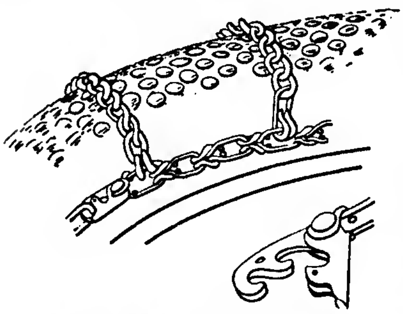


Dayton "airless" tires have a non-skid tread, formed by a novel method of grooving the surface rubber.

quick-detachable variety.

The Fisk demountable, designed especially to comply with the Fisk Rubber Company's ideas concerning the mechanical fastening of tires, has already been on the market several seasons and is quite familiar. It is another through-bolt type, in which the usual lugs are replaced by a continuous ring which encircles the rim and clamps it on by the pressure of the bolts. The valves of the tires used on this rim do not pass through the felloe, but come out diagonally at one side.

The anti-skid chains made by the Fox Metallic Tire Belt Company, of New York City, have their links stamped out of sheet metal. They are bent and interlocked, giving the effect of a flat steel band, with small square projections which make contact with the road surface. These cross chains are attached by side chains of the usual type, drawn together by a patent clamp with a lever to secure a good tension and prevent noise.

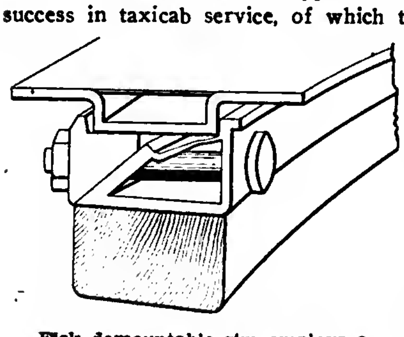


Weed chain grips in improved form, with the snap connection shown in detail beneath.

The Indianapolis company which makes the G. & J. tires has nothing of startling novelty to offer, depending on its standard line of clincher, Dunlop and quick-detachable types, all of which are made with either smooth or Bailey tread. One of the veterans of the tire business, the G. & J. Company, keeps on making the best tires it knows how, with its long experience, and automobilists certainly are not backward in investing their hard-earned cash in its product.

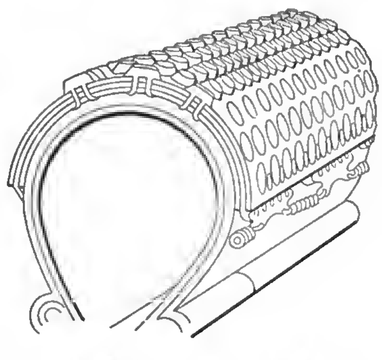
The Palmer web tires which have been used with such success on electric cars during the past season, come from the Akron, O., factory of the B. F. Goodrich Company, another veteran of the industry. It is claimed that the use of these tires has exceptionally good influence upon the single-charge mileage capability of the average electric. Of course, the standard clincher pneumatics are not being neglected; a specialty is being made of interchangeable odd sizes for cars sent out with undersized rims.

In addition to its Bailey tread non-skid the Goodyear Tire & Rubber Company, of Akron, O., has brought out a heavier non-skid of the raised diamond type. This is expected to find much success in taxicab service, of which the Goodyear Company is making a specialty. The Doolittle demountable-detachable rim, operated by turnbuckles, which this company recently adopted, is set forth in a comprehensive exhibit. It is one of the cleverest devices of the sort that has yet happened and deserves its remarkable success.



Fisk demountable rim employs a continuous ring as retainer, held in place by bolts.

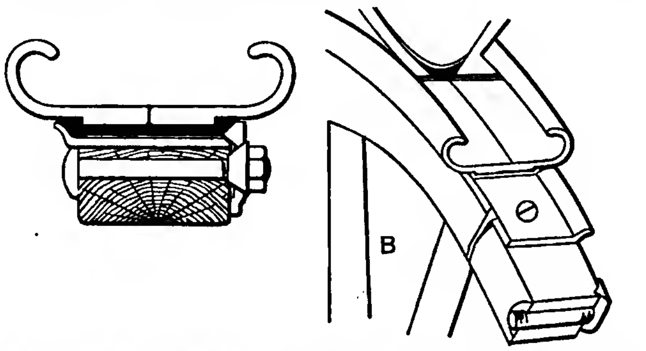
The Hartford Rubber Company, of Hartford, Conn., was one of the first to push the Dunlop style of tire, and still finds a large demand for it, in spite of the competition of the quick-detachables of the clincher style. The Hartford non-skid with the coils of steel spring wire encircling the tread has proved a great success, and now occupies a leading position in the company's output. Its multiplicity of claw-like points prove just the thing for greasy asphalt pavements.



Detachable non-skid treads are featured by the Woodworth, with side springs for tension.

Woodworth tire treads in several styles form the exhibit of the Leather Tire Goods Company, of Niagara Falls, N. Y. These are of leather, steel-studded and are detachable at will. In position they are held snugly against the tire by a series of coil springs along each edge. The Woodworth tire chain is of the usual type, but takes the precaution to interpose between each chain and the tread of the tire a strip of heavy leather, to protect the latter from abrasion.

The anti-skid type featured by the Michelin Tire Company, of Milltown, N. J., is steel-studded, the studs being imbedded

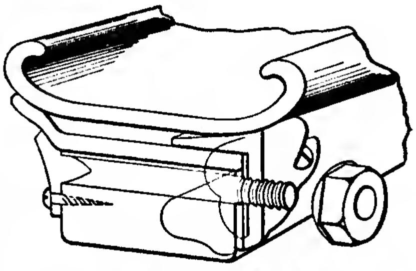


Perspective and cross-section of the Nadall demountable-detachable rim, from Chicago. Note the split slincher rim, which falls apart on the removal of the locking ring.

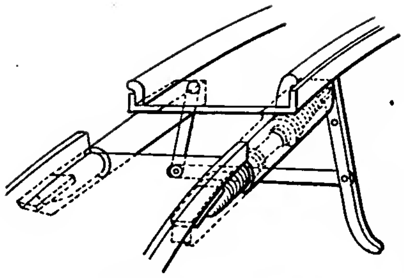
in a leather tread which is vulcanized to the rubber. These rivets, of soft steel, after being turned to shape, are chilled to give a glass-hard surface. The Michelin demountable rim, of the through-bolt type, has been on the market for a comparatively long time. The lugs have a rather thin wedge end which enters well under the clincher rim and gives a strong grip.

Morgan & Wright, of Detroit, have a new non-skid called the "Nobby," which is not slang, but describes the appearance of the tread. Raised oblong knobs encircle it in transverse rows, the rows running spirally with the alternates in opposite directions. The general idea is that often employed on the driving wheels of traction engines; thus the old saying is again proved, that there is nothing new under the sun. Still, the "Nobby Tread" will be found on many wheels next summer.

The Motz Clincher Tire & Rubber Company, of Akron, O., is a firm believer in the solid tire as against the pneumatic. The Motz idea is to secure resiliency by providing a deep cross-section for the tire, in which the rubber is cut away just under the tread. Thus, although there is ample wearing surface in contact with the road, the thinner portion provides a sufficient degree of resilience for all uses.



Demountable rim shown by Diamond, retained by a series of bolted wedge-shaped lugs.

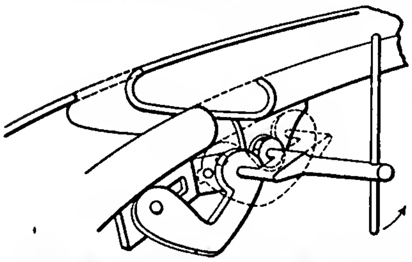


Doolittle demountable rim, adopted by Goodyear, uses twin turnbuckles actuated by one lever.

The exhibit of the Pennsylvania Rubber Company, of Jeannette, Pa., includes non-skids of both the molded rubber and the steel-stud types. The former is provided with a tread of a special hard white rubber held to the body of the tire by a strip of fabric impregnated with a special compound. Another form is a suction-cup tread, which is provided with a series of rubber knobs hollowed out in their centers. They are claimed to be very efficacious on greasy pavements.

The staggard tread, which was one of the earliest forms of the molded rubber non-skid, is again shown by the Republic Rubber Company, of Youngstown, O. The tire has a series of oval projections in rows running circumferentially of the tread. The rows, some five in number, overlap each other so as to form a surface of continuous roughness. The Republic exhibit shows a number of manufacturing samples illustrating the manner of forcing the rubber into the fabric of the tire in order to secure the permanent union.

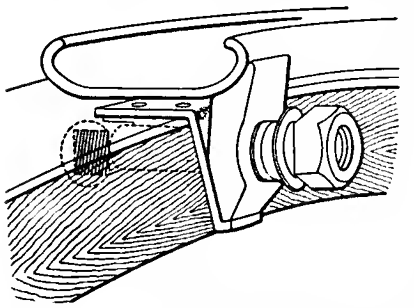
The vulcanizers made by the C. A. Shaler Company, of Waupun, Wis., are one of the experienced automobilist's constant companions, and have saved many a dollar in tire bills. They are now made in small sizes suitable for motorcycles, and have also been adapted to the use of electric current for the heating. These latter have an automatic heat control. They are made in sizes adapted both to the garage man and to the private owner.



Showing special tool required for the Universal demountable, which has a split rim.

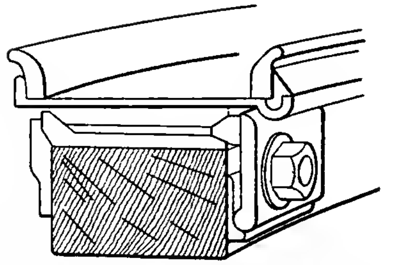
Native of Chicago is the Nadall demountable rim, made by the Nadall-Van Sicklen Company. It incorporates a quick-detachable scheme which has proved very successful. It is a through-bolt design, with a continuous circumferential ring instead of lugs. The quick-detachable idea is simply the splitting of the clincher rim circumferentially. The two halves are normally held together by a ring of spring steel, but may be easily separated. Then they fall apart and leave the tire absolutely free.

Standard solid cushion tires for clincher rims are shown at the stand of the Swinehart Clincher Tire & Rubber Company, of Akron, O. These are made for all kinds of pleasure and commercial vehicles, and are especially adapted for taxicab service. In addition the Swinehart Company is now marketing a clincher quick-detachable pneumatic tire. The quick detachable rim has a bolted flange which can be operated without any tool except the ordinary wrench.



On the Empire demountable rim the retaining lugs do not have to be removed completely.

The "Universal" tire protector, made by the company of the same name at Angola, Ind., is a heavy chrome leather band studden with hardened steel rivets. The protectors are easily detachable, though they are recommended for constant use in all weathers, fair or foul. The constant tension devices fitted on these bands are especially neat, and are claimed to prevent creeping of the tread under any condition.

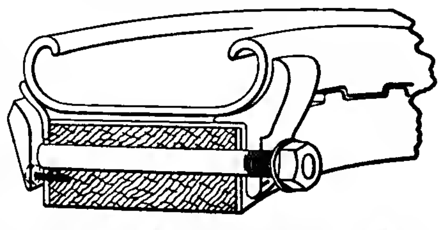


Firestone has a quick-detachable rim mounted demountably, of the bolt-retained type.

Weed tire chains, made by the well-known New York Company, have a firm grip on the affections of the autoist, as well as on the roads his car travels. For the 1910 product no change was found necessary. The only alteration has been the employment of a special grade of steel which would take the hard surface required by the work without becoming brittle. The Weed line now comprises no less than 76 different sizes.

The Universal Rim Company, of Chicago, is making a demountable rim of the type in which the clincher rim is sawn across, and the ends forced apart in order to remove the rim from the felloe. This is accomplished by an ingenious linkage, operated by a special key and lever; a single half turn of the lever is sufficient either to remove or replace the rim.

Hard though it may be to pick out any part of the automobile in which satisfactory service enhances the pleasure to be derived from the car, to the exclusion of other parts, yet most will agree that the tires are the most essential in this respect. It cannot be denied that in the past tires have been the automobilist's bugbear, even more so than ignition and carbureter troubles. The worst thing about a puncture or blowout has always been that it required considerable expenditure of the coin of the realm to set it right, whereas vibrators and auxiliary air valves could be adjusted without expense by the owner.

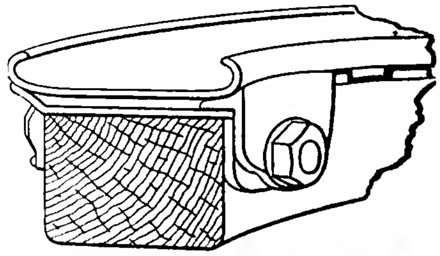


Precautions are taken by Michelin against creeping of the rim on its base, the felloe, which would shear off the valve-stem.

Innumerable attempts have been made to secure a satisfactory substitute for tbe pneumatic, and, as the descriptions above will show, some of these are meeting with considerable success. Yet the pneumatic remains the standard, and seems likely so to remain. The degree of perfection now reached is evidenced by the guarantees of 5,000 miles service which are made by several manufacturers.

Tires for commercial service are further from the point of finality than those for pleasure vehicles. For the heaviest trucks even solid rubber is often unsatisfactory. Wood blocks, and even aluminum and steel bands are used, though so far without exceptional success. Hardly a month passes without the announcement of some form of spring wheel, but these, too, have failed to secure wide recognition.

For medium-weight commercial vehicles pneumatic tires are invading fields hitherto the exclusive realm of the solid tire. The invention of the double and triple pneumatic, with two or three tires side by side on the same wheel, after the familiar arrangement of solid tires, has been the cause of this.



Retaining lugs of the Continental are neatly shaped and project no more than necessary.

Distance Revolution and Time Counters

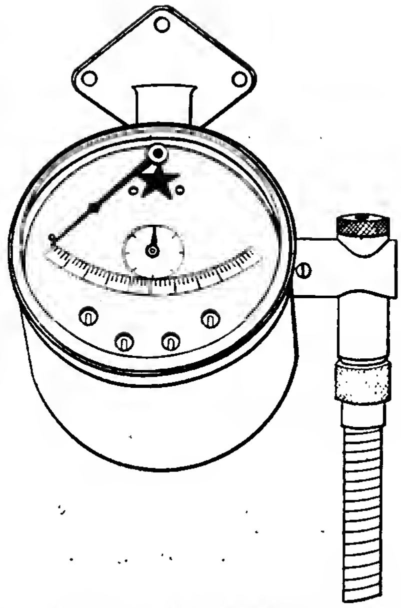
SPEED, time and distance are sources of the automobilist's greatest pride, and form the standard whereby he measures the superiority of his vehicle over all forms of transportation involving the horse. So it is that few cars are found without some instrument for measuring these quantities. But the odometer and speedometer are not limited in their usefulness to fostering pride, no matter how justifiable; they serve the business man in the verification of his accounts and the checking of expense accounts to prevent waste.

One of the most complete and varied lines offered for the show-goer's inspection is that of the Auto Improvement Company, New York City, which markets its products under the trade name of "Ever-Ready." Odometers, speedometers and clocks are shown in no less than fourteen styles and combinations. The speedometers belong to the centrifugal type, which claims the advantages of being immune to changes from climatic conditions. Neither are they over-sensitive to minor variations; on the contrary, the hand is very steady, at any speed from one mile an hour up. Part of the factory test to which each speedometer must submit before being delivered to the purchaser is a trip of 2,000 miles on the bench.

Three different sizes are made, with dials 2 5-8, 3 and 4 inches in diameter, registering to 50, 60, 70 or 80 miles. The driving shafts are constructed with great care, a steel monocoil being used, protected by a brass, steel-lined casing. The Auto Improvement Company has a special line of clocks built for automobile use, for which it claims many good points. These are sold either separately or in combination with other registering instruments.

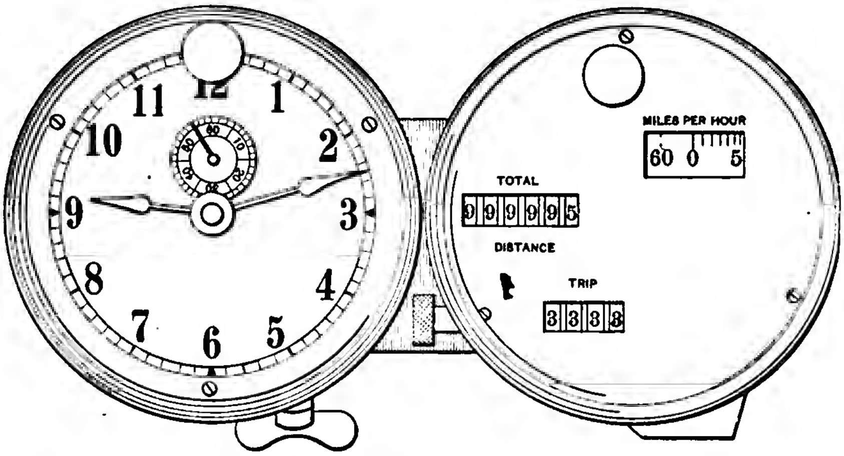
The Hoffecker Company, of Boston, Mass., has on hand its jolting machine to give spectators an ocular demonstration of the steadiness of "the steady hand." A frame is provided, loosely mounted, and with a cam mechanism which gives it frequent and violent shocks; on this is carried a speedometer driven at a constant speed. The frame jerks about in all directions, yet without affecting the indicating hand of the speedometer.

The Hoffecker is offered in three sizes, with 3, 3 1-2 and 4-inch dials, reading to maxima of 50, 60 and 90 miles respectively. With the smallest of these, which sells at a moderate price, a separate season and trip odometer of a well-known type is provided, attached to the outside of the case. The other two styles have a special Hoffecker odometer built in with the speedometer mechanism. This odometer differs from the usual form in that the trip mileage is indicated by a hand moving on a scale concentric with that of the speedometer proper, either inside or outside of it. The figures of the season odometer show through a window in the usual fashion. The Hoffecker operates on the centrifugal principle.

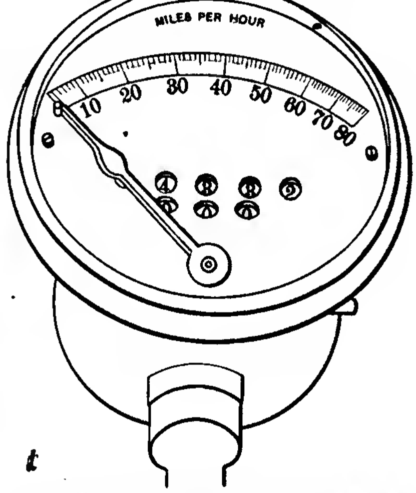


Star speedometer reverses usual arrangement of scale, with pivot at the top end and dial at the bottom.

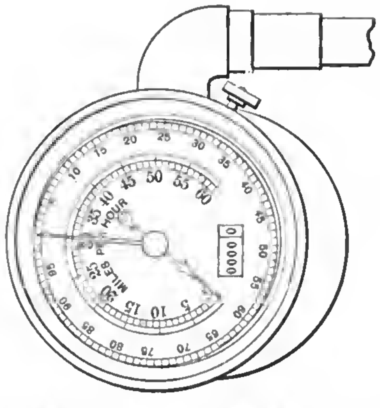
That busy little instrument, the Jones "Live-Map," is exhibited on the stand of the Jones Speedometer Company, of New York City, and attracts as much attention as it did at the two New York shows. The idea is to print the directions for a trip of a hundred miles on the rim of a cardboard disc, and to mount the disc in a frame with gearing to the front wheels in such a manner that it will be rotated at a speed proportional to that of the car. With the proper adjustment, a stationary hand on the frame will then always point to that part of the card which bears the directions for the road which the car is at that moment traversing. This presupposes, of course, that the car follows the route exactly, without side excursions. An adjustment is provided, however, which permits the card to be adjusted at any time to the position the car occupies. The cards are about ten inches in diameter, each bearing directions for a hundred miles of road, and about 600 different ones have been prepared by the Touring Club of America for use in the instrument. The usual line of Jones speedometers is shown, differing in few respects from those of 1909, combined in various ways with odometers.



Neat combination of clock and speedometer-odometer brought out by Warner as a member of the "Autometer" line. The odometer figures read to 100,000 and 1,000 miles for season and trip, and provision is made for electric lighting.



Compact instrument from the Jones factory, with scale reading from zero up to 80 miles an hour.



The trip odometer reading from a scale by an indicating hand distinguished the Hoffecker.

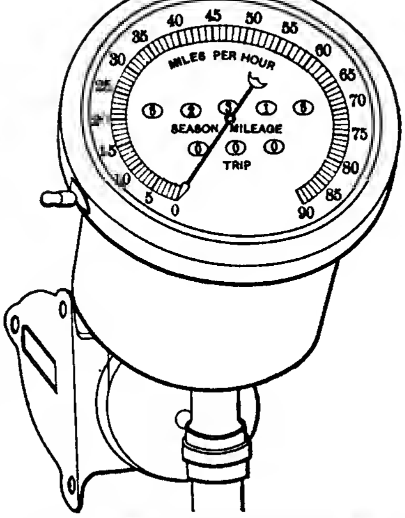
"Multipolar" speedometers are shown in various forms on the stand of the Stewart & Clark Mfg. Co., of Chicago. An especial feature, one which is usually associated with the Stewart product, is the method of mounting on a standard bolted to the frame of the car, instead of on the dashboard. The Stewart speedometers, however, are also made for attachment in the customary way, and both styles can be had in twin form with clocks.

In principle and operation the Stewart instruments do not differ from forms already found satisfactory. The principle, of course, is magnetism, the influence of a rotating magnet on a floating disc held by a spring, which attempts to follow the magnets. These latter, four in number, are imbedded in a ring-shaped rotor driven from the front wheel. They are made of imported tungsten steel, accurately machined. The central stud which carries the rotar receives in turn a spindle, mounted on a jewel bearing, which carries the following disc. Being made of a special alloy metal, this has a low resistance. It is also very light, even in connection with the indicating hand mounted on it, so that the hand moves freely.

Chief among the instruments which sell at a price gauged for the pocketbook of the man of average means is the "Star," the product of the Star Speedometer Company, of Danville, Pa. In appearance it is unostentatious, being in shape cylindrical and set to be mounted at an angle, with the dial on the upper face of the cylinder. The indicating hand is pivoted not at the center, but at the extreme upper and forward edge; it swings over an arc of perhaps 90 degrees on a scale graduated from zero to 50 miles by regular intervals. The odometer mechanism reads to four figures, the figures appearing in windows outside the speedometer scale; there is also a fractional hand, like the second hand of a watch, inside of the scale, reading by eighths..

The low price of the "Star" is claimed to be due to simplified design and modern methods of manufacture. Its gear cutting is done accurately, and the bearings are as nearly free from friction as it is possible to make them. Neither has the external finish been slighted. The flexible shaft drives through bevel gears into the side of the instrument.

Tachometers, as shown by the Veeder Mfg. Co., of Hartford, Conn., are, in reality, nothing more than what the public is accustomed to call speedometers. Their design depends on the principle of centrifugal force, but in an entirely different application from that commonly seen. The working part is a little centrifugal pump, like that used for circulating water in cooling systems. The liquid which fills the pump and the tube above it does not circulate, however, but is driven more and more completely out of the pump casing the faster the paddle wheel goes round. This action causes the liquid, which is red in color, to rise or fall in the glass tube above the pump, and a scale shows the speed to which the level corresponds.

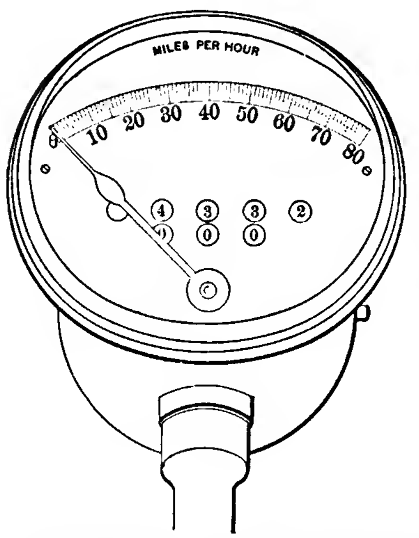


Exceptionally long scale is secured on the Stewart instrument reading up to as high as 90 miles.

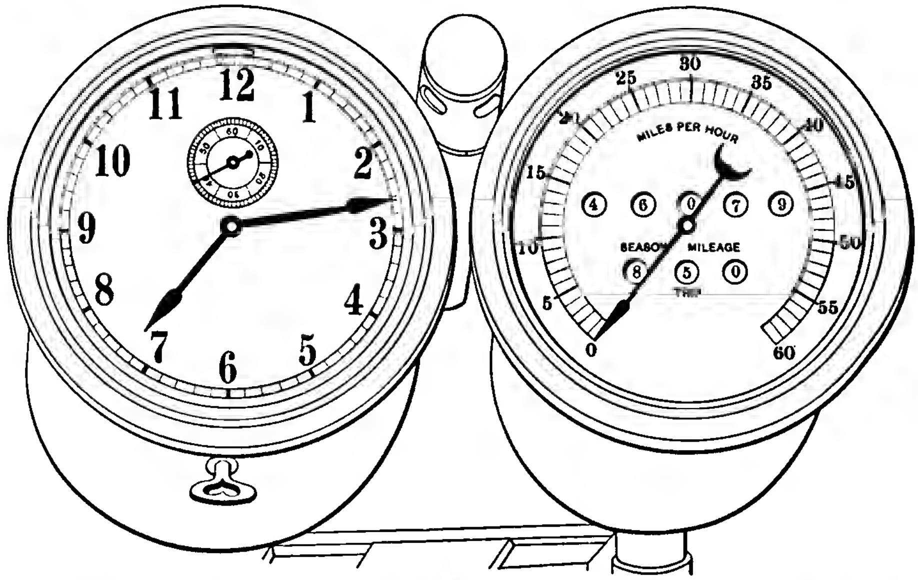
As long as the liquid stands at the zero mark when the car is at rest, the readings must be correct. If any of the liquid should leak out or evaporate, this fact would be indicated by the falling of the level below zero under this condition; it can then be adjusted by means of a small nut.

"Autometers" appear on the stand of the Warner Instrument Company, of Beloit, Wis., both in the form in which they first won the attention of the automobilist, and in the newer form in which they were first seen last year. The mechanism of the two are, of course, identical. Their distinctive feature is the use of a band with figures which appear in turn in front of a window, instead of an indicating hand. It is claimed for this system that it is possible to have a separate figure for each mile an hour of speed, amounting in effect to an indicating scale of many times the usual length.

These instruments work on the familiar magnetic principle, the magnet rotating and exerting a dragging influence on the spring-retained band. The odometers shown in combination with the newer forms read to 100,000 and 1,000 miles on their season and trip faces, instead of the customary 10,000 and 100 miles.



Another form of the Jones speedometer, differing slightly from that which was previously shown.



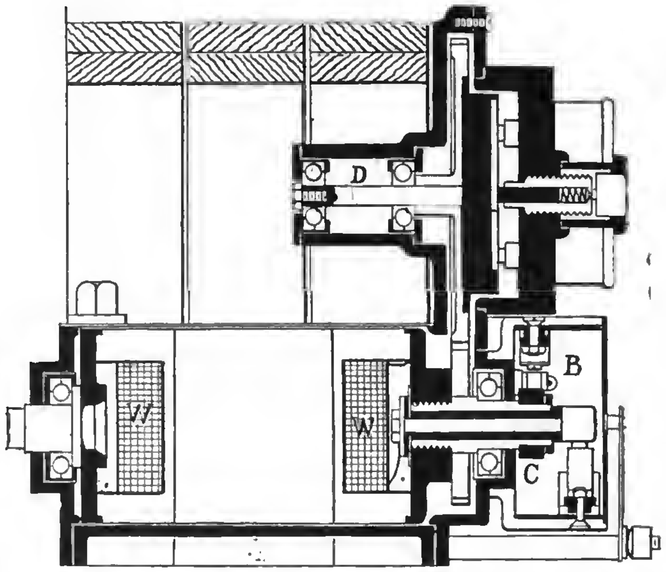
Twin instrument, with clock, of the Stewart Company, working on the magnetic principle; at night the combination may be illuminated by an electric bulb in the central turret, which is provided for that purpose.

Magnetos and Auxiliary Ignition Systems

PRINCIPLES of electricity, as applied to automobile ignition, are becoming more widely understood, and there is a corresponding increase in the number of systems offered to the public. Some of these, it is apparent, are the result of much painstaking experimentation, being applications of laws formerly understood only in research laboratories. Others are but new forms of old principles, depending for their merit on mechanical ingenuity and skill in design.

Among the oldest manufacturers of electrical ignition appliances in the country is the Apple Electric Company, of Dayton, Ohio. The regular Apple system employs a dynamo in connection with the storage battery and coil. In fact, the system differs from that which a few years ago was universal, namely, the battery, four-coil and timer system, only in the provision of the dynamo, which in service is constantly recharging the battery.

The Electric Storage Battery Company, of Philadelphia, will exhibit as usual Exide batteries suitable for electric pleasure and commercial vehicles, Exide sparking batteries and Exide lighting batteries. The latter are used, among others, by the Packard Motor Car Company to provide current for the dome lights in all Packard limousines. Exide ignition batteries are offered in two forms; one in the conventional way, with the usual number of cells, wired in series, in a wooden case, and the other with an emergency battery in the same case. The emergency battery is, of course, of the same voltage as the main battery, but has a smaller amperage capacity, being good for but a few hours' continuous usage. This, however, is usually sufficient for the automobilist to reach a charging station. The idea is like the reserve gasoline tank, which is almost universal.

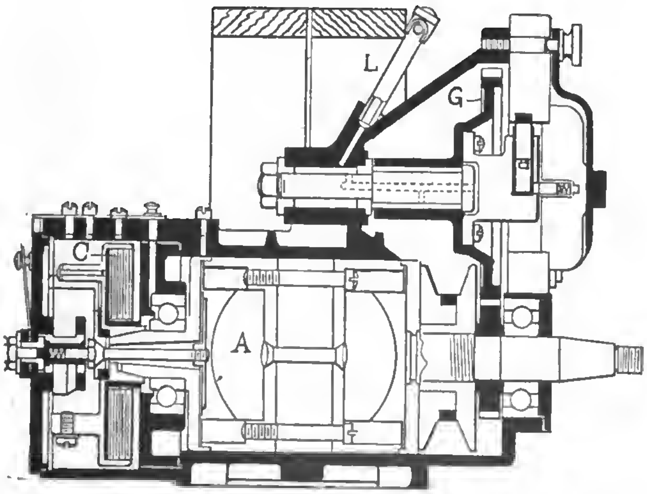


Splitdorf magneto shows thorough use of annular ball bearings, the distance between the bearings on the armature shaft being comparatively short to minimize bending strains on this part.

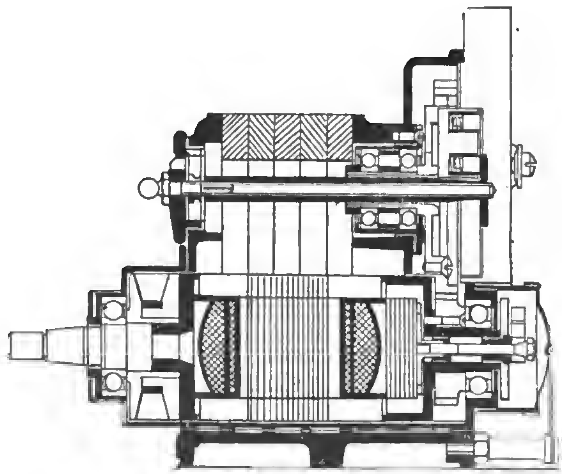
At Chicago, as at both the New York shows, the R. E. Hardy Company, of Detroit, will exhibit, in addition to its line of "Sta-Rite" plugs, a new plug called the "Apropos." The porcelain of this plug, at its business end, is hollowed out in a conical form, through the center of which the electrode projects.

The Seeley ignition system and the Seeley duplex magneto are shown by the High Frequency Coil Company, of Los Angeles, Cal. The 1910 system is identical with that of last year. The electric current, which may come from either a magneto, a storage battery or a dry battery, is led through a non-vibrator coil with a condenser wired in parallel. From this the current goes through a single wire to a roller type of timer on the motor. The timer sends the current to the four cylinders in turn, by way of the resonators mounted on each cylinder. These in external appearance are small cylinders, seated on a bracket close to the spark plugs, to which they are connected by brass strips. Within each resonator are two windings, a primary of three turns, and a fine and dense secondary. The induced high-tension current in the latter in turn bridges the gap of the sparking points.

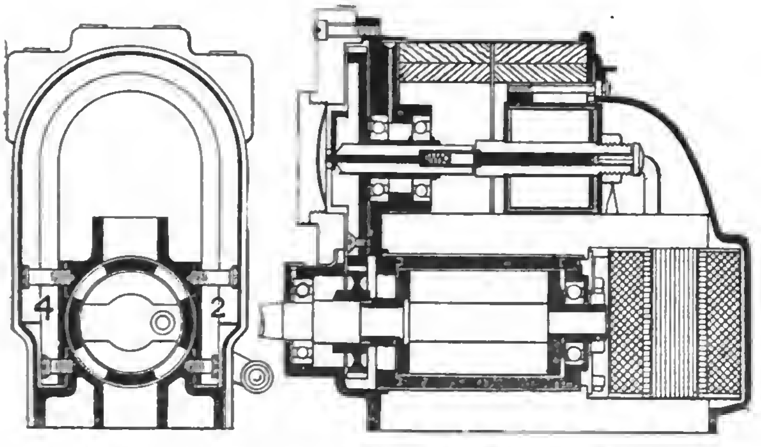
A complete line of electrical apparatus, and some other kinds, constitutes the exhibit of A. R. Mosler & Co., of New York City. Among these may be noted "Spit-Fire," "Triumph" and "Beat-em-All" spark plugs, "Umph" timers and distributers, Mosler roller timers and distributers, self-snap controlling levers and cut-out levers and "Isti" rear signals.



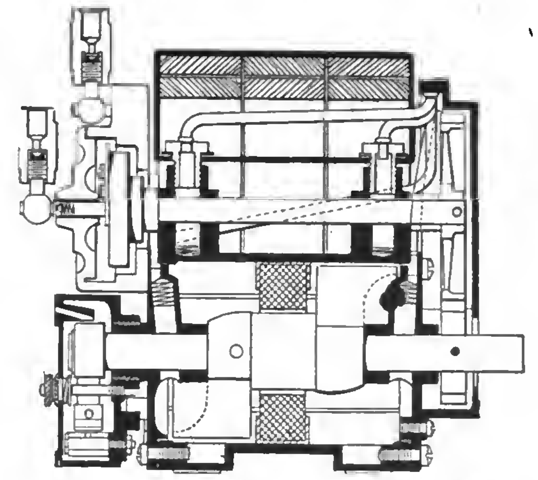
On the Kingston magneto the condenser is mounted concentrically with the armature, just inside of the contact-breaker, thus making the shortest possible connections.



Complete enclosure is a feature of the Herz magneto, the magnets being set close together and the ends closed in with plates; ball bearings are used throughout on both shafts.



On the Pittsfield magneto the coils in which the high-tension current is induced are mounted just behind the armature, and are always stationary; this arrangement allows them to be better insulated.

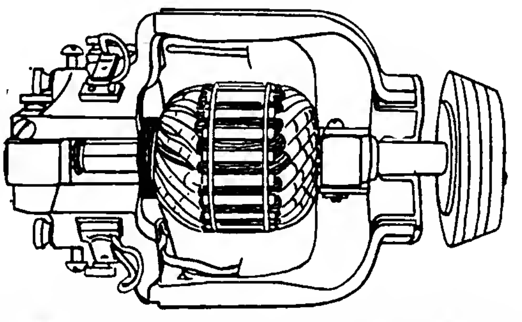


Compactness distinguished the Remy magneto, together with its original form of ball snap terminals for the high-tension leads.

Dry batteries still find considerable favor in ignition, being especially highly regarded as an auxiliary for magnetos. In this line the "Columbia," made by the National Carbon Company, of Cleveland, Ohio, has always occupied a position of pre-eminence. Advantages claimed for these batteries are that they may be replaced at a nominal cost when exhausted, instead of having to be recharged, like a storage battery, which means either the loss of the use of the battery for a considerable period of time, or else the greater investment of two batteries; further, they contain no acid, so will not slop and spill, or corrode terminals, and are water and weather-proof. The particular feature of the "Columbia" line is that these batteries give notice of their approaching exhaustion from 100 to 200 miles in advance of the point where they become useless.

"Monarch" spark plugs and timers are shown in various styles by E. M. Benford, of Mount Vernon, N. Y. The "Monarch" porcelain plug is simple in design, with electrodes projecting well into the combustion chamber. In mica-insulated forms the whole central core projects to meet the grounded electrode. The magneto plug, also mica-insulated, has a core of twice the usual thickness, so that the heat, oil and extreme high-tension current of magneto service can have no ill effect upon it. The insulated electrode has an inner head of crown shape, providing a multiplicity of sparking points wherever the points of the crown approach the cylindrical continuation of the outer shell.

The B. & S. igniter, which is made by the Briggs & Stratton Company, Milwaukee, Wis., is a device designed to replace a magneto, by accomplishing the ignition of an ordinary engine very economically from a set of storage or dry batteries. It is claimed that a four-cylinder engine will show 2,500 miles on one charging of a 6-60 storage battery. The device consists of a complete ignition system designed to be mounted rigidly on the engine base and driven by the shaft ordinarily provided for the timer. This case, 5 inches in height and 3¼ inches in diameter, contains a non-vibrating spark coil, a condenser, a positive make-and-break mechanism and a high-tension distributer to the plugs.



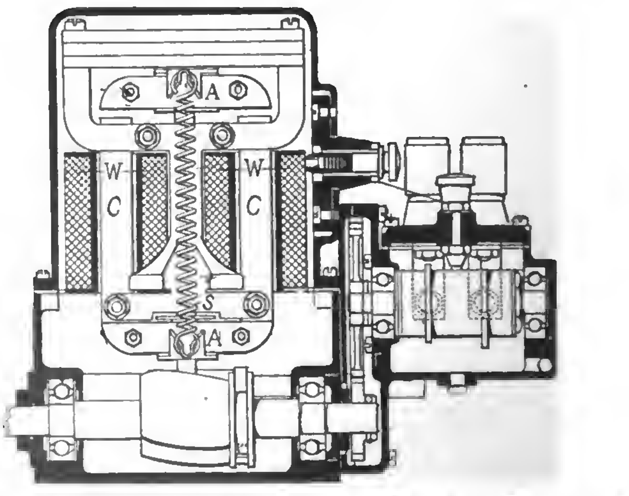
Dynamo generation of the ignition current is favored by the Apple Electric Company; the Apple machines are designed to be driven by a friction pulley on the flywheel.

In addition to Kingston coils, switches, timers and spark plugs, the Kokomo Electric Company, of Kokomo, Ind., has brought out for the coming season a magneto, of the standard type, but offering some refinements. Annular ball bearings are used throughout. The armature has a high-tension winding, making the magneto one of the true high-tension type.

"Soot-proof" spark plugs are shown by C. A. Mezger, Inc., of New York City. As this plug has been on the market for some time and is a favorite among automobilists, it is scarcely necessary to state that it still retains its characteristic feature, a long, straight electrode seated in a deep annular chamber, the walls of which form ample insulating surface. Even though the latter should be completely covered with soot or carbon, the resistance of the path thus formed would be so high that the spark would jump between the points in preference.

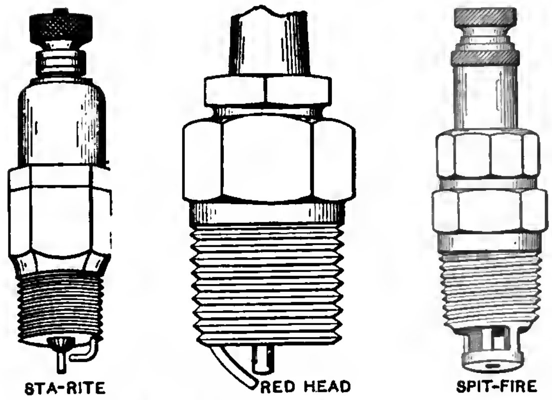
The chief exhibit at the stand of the Heinze Electric Company, of Lowell, Mass., is the new Heinze magneto. This attracts the eye through the shape of the horseshoe magnets, which are round in cross-section, instead of rectangular—that is, before bending they are rods rather than flat strips. The ends of the magnets are tapered and forced by pressure into correspondingly tapered holes in the pole-pieces, giving a very intimate contact. The armature core is of cast iron, and of the shuttle type, but the slots are not as deep as usual. The winding has fewer turns, also, the claim being that this is compensated for by cutting a greater number of lines of magnetic force on each revolution.

The Atwater-Kent spark generator is shown in a form closely resembling that of 1909, together with the Unisparker, which was new last season. As is well known, the great advantage of this system is its economy of current consumption, but one spark



The Witherbee represents an entirely new idea in ignition devices; it is claimed that it will generate sufficient current for starting by turning the starting crank.

being made for each explosion, instead of six or seven, as is the case with vibrator coils. In the spark generator the whole mechanism is placed on the dash and driven by a positive connection with the camshaft of the car; in the Unisparker the contact maker and distributer are placed on the engine, and the condenser and spark coil are placed on the dash, thus doing away with a separate drive shaft.



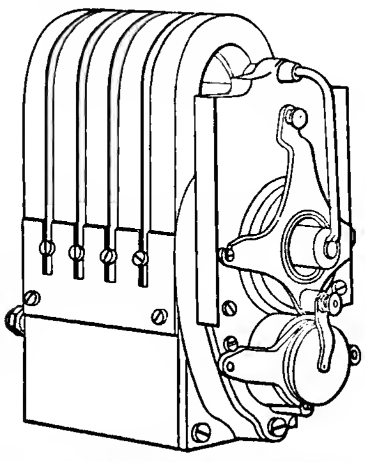
Illustrating three standard types of American-made spark plugs, two being porcelain-insulated and one using mica for this purpose.

The complete line of magnetos made by the German firm of Unterberg & Helmle is shown at the stand of the J. S. Bretz Company, of New York City. These are listed in nine sizes, two of which, designed for large motors, are fitted with the special U. & H. spring device, which produces a spark no matter how slowly the motor is cranked. A new form is that adapted for use in dual ignition systems; a special dash coil and switch has been provided for use with it, as the magneto is of the true high-tension type. The condenser is mounted on the end of the armature and revolves with it, so that a number of brushes and other connections are eliminated.

The Connecticut Telephone & Electric Company, of Meriden, Conn., recently announced the addition to its line of a magneto. Attention has been paid to the adapting of the magneto to the understanding of a man of limited mechanical education, such as are more and more to be found in the possession of automobiles. One feature in particular is the provision of a separate spark gap for each cylinder; in case that cylinder is not firing the spark will jump the safety gap and will be visible through a window. Another point aimed at was efficient sparking at low speed, so that it will not be necessary to spin the starting crank in order to start the motor.

Two types of Eisemann magneto are marketed by Lavalette & Co., of New York City. The original Eisemann, which was a low-tension with separate coil, is continued, but there has been added a true high-tension type, with secondary winding on the armature. Both employ pole-pieces of a helicoidal shape, whereby the magnetic lines of force are progressively broken and reestablished. A spark advance of 35 degrees has been made possible, the method being the shifting of the steel shoes on which the fiber block of the make-and-break device works. The same company has a dual ignition system, with non-vibrator dash coil and switch, for starting from the seat.

An entirely new magneto for primary ignition is shown by the Motsinger Device Manufacturing Company, of Pendleton, Ind. It is driven by a friction governor pulley and operates equally well in either direction. It generates a direct current, and is intended for use with the regular equipment of spark coils and timer. The familiar "Auto-Sparker" has by no means been superseded, however, being still on the job, and this year capable of a slightly greater amperage output than formerly. It is suited for charging 6-volt storage cells and can carry a load of six tungsten lamps each 6 volts and ½ impere.



K-W magneto, in which all working parts are of chrome steel, ground and lapped.

Coils insulated in glass form the exhibit of the National Coil Company, of Lansing, Mich. The efficiency of glass as an insulator is proven by its use in many other situations in electrical engineering where an insulator of great reliability is required. The National coils are claimed to be proof against all leakage of current and cross-induction between coils, thus eliminating one of the most prolific sources of missing, mis-firing, slow action, large fuel consumption and run-down batteries. In appearance these coils differ in no way from standard, the usual hard rubber insulation being simply replaced by glass. This material is naturally of an exceptional quality, to stand the hard service.

The "Never-Miss" spark plugs, guaranteed for one year, are shown by the Never-Miss Spark Plug Company, of Lansing, Mich. These plugs are made in two types, one for magneto use with four grounded points surrounding the central electrode, and the regular design with both points of the projecting wire form. The exhibit includes an auto clock, to be fastened to the steering wheel rim; ammeters, also guaranteed for one year; battery connections, and chain-repair devices to bring together and hold in place the ends of a broken chain.

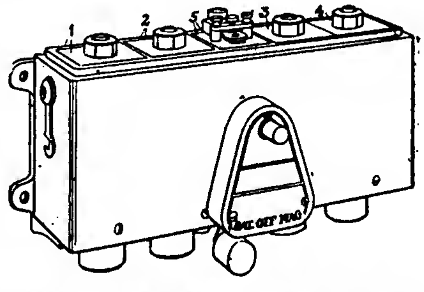
Simms magnetos, made in England by Frederick Simms, of the original Simms-Bosch Company, are imported and sold in this country by the Simms Magneto Company, of New York City. They are of the standard high-tension type, with secondary windings on the armature. In design they show the results of the long experience of their maker in this line of work. The claim is made for them that with six drops of oil every 10,000 miles they will give continuous and reliable service for hundreds of thousands of miles.

A complete line of storage batteries for electric vehicles is shown by the United States Light & Heating Company, of New York City, whose products go under the trade name of the "National" batteries. This concern has introduced new types of batteries, in one of which the plates are of a medium thickness, while in the other they are very thin. It also shows its new line of high-bridge jars.

Remy low-tension magnetos are shown in two models for 1910 at the stand of the Remy Electric Company, of Anderson, Ind. Both types are of the same design, which is well described pictorially in the illustration offered herewith.

The Vesta Accumulator Company shows storage batteries for lighting and ignition purposes. The former are being made a specialty, in view of the great popularity of electricity as a means of illumination. The Vesta magneto, of the low-tension type, which made its début at New York this year, is also on hand. It embodies all the features which have come to be regarded as standard in that type of magnetos which relies on a separate coil for the transformation of the current to a high voltage.

The Witherbee igniter is the latest product of the Witherbee Igniter Company, which started as a manufacturer of storage batteries. Its design differs in many respects from standard, embodying as it does a very successful effort in the direction of providing a good spark at a very low speed, for easy starting of the motor. The lines of magnetic force are cut by a cam-operated device corresponding to the armature, which however works at a fixed rate of speed.



Master-vibrator spark coil brought out by the Connecticut Telephone Company, which has many good features.

Electric Acetylene and Kerosene Lamps

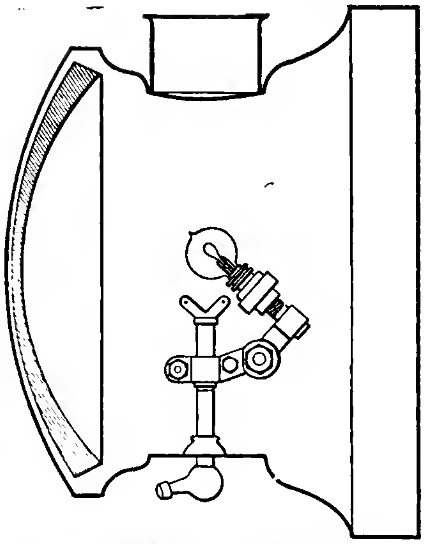
ORNAMENTAL, as well as useful, are the lamps which are now being produced by the leaders in this line. After reaching the nearest possible point to ultimate perfection as light-giving devices, the continued development has been in the line of beautifying the lines and finish.

In simplicity and pleasing though unostentatious effect, one of the leaders is the "torpedo" style of the Solar, made by the veteran lamp-maker, the Badger Brass Mfg. Co., of Kenosha, Wis. The body and flare of this lamp are a single piece of heavy brass, and the door is recessed in such a manner that the front reflector is outside the glass. Two forms of eclipsing devices for city driving are shown. The "Solarclipse" drops a shutter behind the acetylene jet and the back reflector, and the "Raydeflector" shifts the jet out of focus with the reflector.

R. E. Dietz & Company, of New York City, has five sizes of "Majestic" headlights, with several varieties of side and tail lamps. The line of the company has been much reduced by eliminating patterns which were found not up to the required standard; consequently the whole product is now concentrated on a few of the very best styles. New devices are the result of recent demands, among them the "Presto," for changing from oil to electricity, and "Comet," for changing from oil to acetylene.

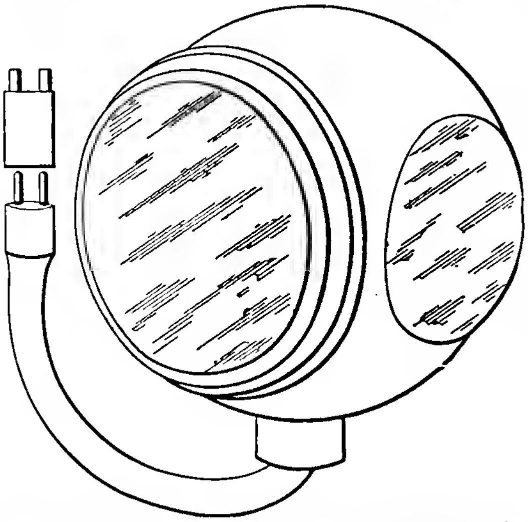
Edmunds & Jones, of Detroit, display oil and electric side lamps and combination electric and acetylene headlights. The latter are distinguished in appearance by their rather unusual length. The flare fronts are integral with the cylinder part, giving a smooth surface. The latest E. & J. development is a condensation cup, to catch the water which is often present in acetylene gas and which always causes trouble unless quickly eliminated. The idea is to arrange the piping so that water will drain into the cup, where it will not interfere with the system.

The leader in the Gray & Davis line is the close-coupled lamp, which has a very short body. The shortness of the body is said to prevent flickering, as there is no body of useless air in which currents may arise. On the other hand, there is more air above and below the jet, where it is the most use. Another Gray & Davis feature is the patent leather finish, a dull black surface which does not require polishing, yet has a rich appearance. A combination electric and acetylene device, very neat in design, forms a part of the exhibit, and seems destined to popularity.



Gray & Davis combination acetylene and electric headlight, as an electric.

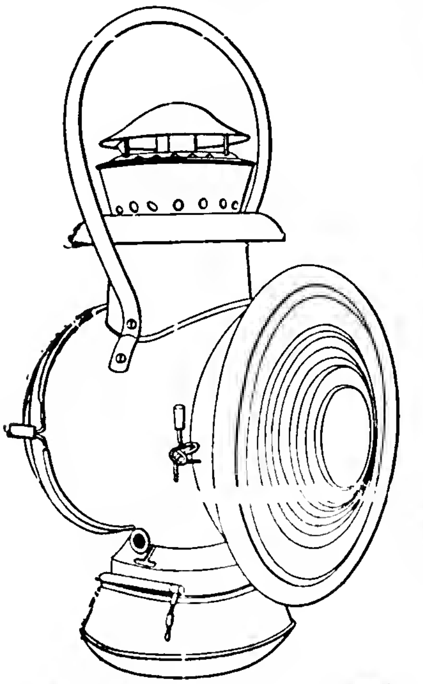
Ham's "Cold Blast" oil lamps, made by the C. T. Ham Company, of Rochester, N. Y., embody features of design which have always secured them a place when the question was one of reliability in light-giving. They are neat in appearance, showing a considerable degree of perfection in design, both from the mechanical and artistic points of view. The doors of the cylindrical body styles are made with bull's-eye lenses of a special design, which is said to greatly enhance their light-projecting qualities.



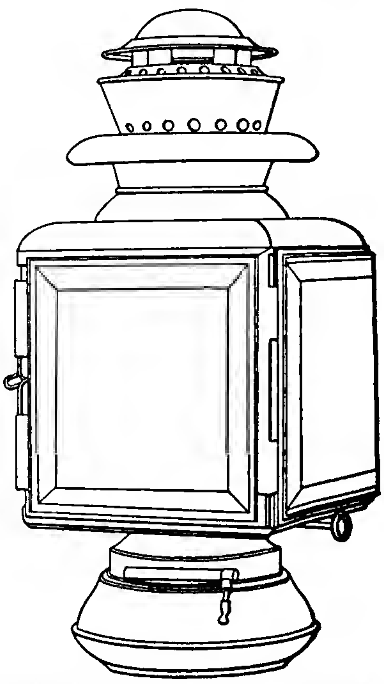
Dietz electric tail-light, in which advantage is taken of electric simplicity to make the shape.

Two distinct tendencies are to be observed in lamp construction, one of them is the movement toward the universal use of electricity, and the other the tendency to provide means of dimming the projected beams of powerful headlights. The latter has been made the subject of not a few city ordinances, and automobilists who live in the affected districts are tired of compliance by such primitive means as whitewashing the front glass, or pasting in a sheet of brown paper—both are common.

As for electric lighting, the great obstacle is the almost universal use of the magneto for the ignition system. The doom of the battery, even as an auxiliary, was already in sight when electric lighting first became popular. The majority of magnetos are not used for lighting.



Cylindrical-bodied Ham oil side light, with bull's-eye front lens.



Ham square-bodied, oil-burning side light, known as the "Coupé" style.

Carburetors and Fuel Accessories

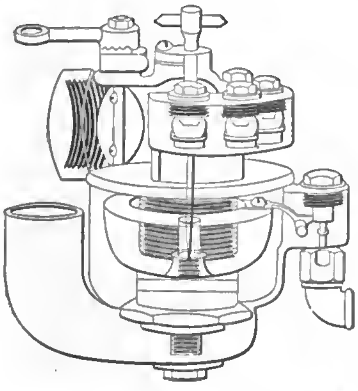
FUEL systems are covered in complete by the exhibits, ranging from the gasoline storage tank, through pumps and other distributing mechanisms to the gasoline tank of the automobile, thence through intermediate devices to the carbureters; one new device provides for the further mixing of the gas after leaving the carbureter for the motor cylinders.

The S. F. Bowser Company, of South Bend, Ind., shows its well-known and reliable line of storage tanks and pumps, which have become a standard. These are built to fulfill any requirement for either a public or private garage, providing a safe and convenient storage. The tanks are located outside of the building, and are filled from the outside; the pump, on the contrary, is on the inside, and delivers the required amount of gasoline into the tank of the car without exposure to the air.

The Breeze carbureter, shown by the Breeze Carbureter Company, of Newark, N. J., is distinguished by such modern features as the venturi-tube suction chamber surrounding the gasoline jet, and the concentric float. The gasoline and air adjustments are both placed on top of the carbureter, the former having figures and graduations stamped on a dial head to indicate its position. The auxiliary air valve is claimed to be noiseless in action, and the longer it is in use the better it seats. The shape of the needle valve, which comes down into the opening of the nozzle, causes the gasoline spray to be broken up into the finest particles. This company also makes a gasoline strainer and various forms of engine connections.

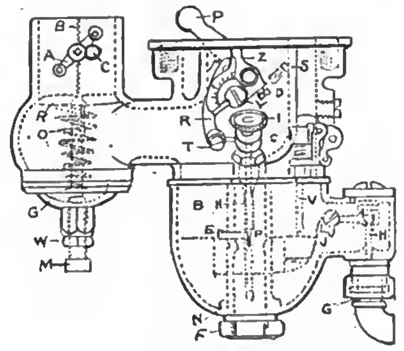
An interesting type of auxiliary air valve may be observed on the Kingston carbureter, exhibited by Byrne, Kingston & Company, of Kokomo, Ind. It consists of a series of ball valves, which the suction of the motor causes to lift in turn, progressively, from their seats. The openings in the seats on which the balls rest are cups or inverted cones of different tapers. The top of the gasoline nozzle forms a cup, the upper edge of which is somewhat above the narrowest part of the chamber.

The clever little device brought out by the Gasoline Motor Efficiency Company, of Jersey City, N. J., under the trade name of "Homo," is favorably staged. This device, it will be remembered, is intended to be inserted in the inlet pipe between the carbureter and the motor. It consists of a screen of coarse wire mesh, behind which is a ball-bearing fan. The passage of the stream of mixture causes the fan to rotate and break up the particles of liquid gasoline, thus assuring a uniform gas charge.



Kingston carbureter, showing row of ball valves for auxiliary air.

The Bowers carbureter, an unusually simple and compact device, is exhibited at the stand of the Gilbert Mfg. Co., of New Haven, Conn., successor to the F. E. Bowers Company. Like many other carbureters of recent date, the Bowers embodies the venturi-tube suction chamber and the concentric float. The compact appearance is due largely to the fact that the supplementary air inlet is concentric with the main air inlet. The venturi-tube has a conical-shaped piece inserted in its lower end, surrounding the jet, through which the main air supply enters. The auxiliary air comes in around this central piece and joins the central stream in a mixing chamber above the jet. The shape is such that a whirlpool effect is created in the chamber.



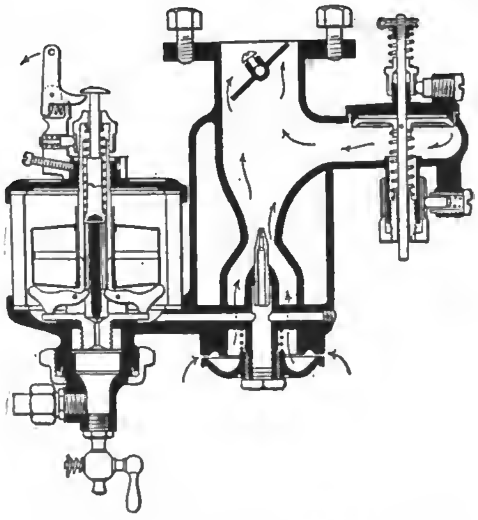
Latest model of Schebler carbureter, retaining original features.

The Holley Brothers Company exhibit the carbureter bearing their name in several forms, all of which are more or less familiar to the public. This company will be remembered as the first to utilize the venturi principle as the exclusive means of proportioning the air supply to the gasoline, and also as the originator of that type known as the "puddle" carbureter, in which at low motor speeds the mixture is by evaporation from the surface of a puddle of gasoline, rather than by a spray. One of the forms offered to the public is the original of this type, in which the float chamber is concentric with the jet, and the automatic air valve is eliminated.

A. R. Mosler & Company, of New York City, show a carbureter known as the M & B, a small and light device with a concentric float. The air passages appear to be in the shape of a letter T, the vertical stem being the main air passage, surrounded by the float chamber and having in its center the gasoline nozzle. One of the arms of the T has the auxiliary air valve in its end, and the other forms the outlet for the completely mixed gas. A butterfly throttle valve is regularly provided at this outlet. The auxiliary air valve is adjustable by means of an easily operated wing nut. The needle valve screws down on the jet from above, and is provided with a graduated nut and spring stop.

The Stromberg Motor Devices Company appears in its home show with a complete line of carbureters of two types, in one of which the float is concentric and in the other located by the side of the mixing chamber. The latter form provides an ample water jacket surrounding the mixing chamber, to compensate for the loss of heat incidental upon vaporization. The transparent glass float chamber, which gives these carbureters such a distinctive appearance, is naturally continued.

Four styles of the Schebler carbureter are shown on the stand of Wheeler & Schebler, of Indianapolis. All of these have concentric float chambers. In three of the styles the air passage traverses the float chamber in the shape of a letter L, with the jet at the angle. In the fourth type the main air passage is straight and vertical, slightly strangled at the jet to secure a venturi-tube effect. The jet comes into this passage at an angle, with an overhead valve.



Stromberg carbureter, with glass float chamber and venturi tube.

Motors Transmissions Steering Gear and Parts

SUFFICIENT for the manufacture of a complete automobile are the parts shown by the assemblage of manufacturers in the galleries of the show buildings. From the motor, gears and axles, down to the smallest and least important accessories, everything needful is there. Crankshafts, cylinder castings and axle forgings appear in the rough, and as finished and assembled into their respective units.

Chains as a method of transmitting power have many advantages which have by no means been lost sight of by automobile manufacturers. They are more efficient than any other known method of transmitting power between parallel shafts, and far superior to any of the methods of transmitting between shafts at an angle. Apropos of which is the exhibit of the Baldwin Chain & Mfg. Co., of Worcester, Mass., which is exclusively devoted to chains and sprockets. A new form of quick-detachable link is featured.

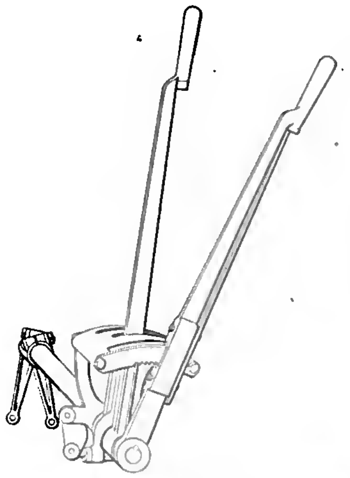
The shipbuilding firm of William Cramp & Sons finds many customers among the automobile builders. It specializes in several alloys of the brass and bronze genera. Parsons white brass is almost a standard for crankshaft and other heavy-duty bearings. Manganese bronze, either in ingots or castings, is also furnished by this company; the castings include many intricate shapes, such as crankcases, gear cases, and front and rear axles.

The Diamond Chain & Mfg. Co., of Indianapolis, is another upholder of the chain as a transmitter of power. The company is very proud of the fact that its chains were selected for use on the Wright aeroplanes, in which they are used to connect the motor with the two propellers.

The Driggs-Seabury Ordnance Corporation, of Sharon, Pa., is preparing to furnish forgings and stampings for crankshafts, connecting rods, axles and frames of various qualities of steel, and in any stage of finish.

Die-cast babbitt bushings are exhibited by the H. H. Franklin Mfg. Co., of Syracuse, N. Y., the maker of the Franklin automobile. These bushings are used throughout the Franklin, and have given such satisfactory service that the company established a special department to make and sell them to other builders.

In the line of steering gears the product of the Gemmer Mfg. Co., of Detroit, comes near to the standard. These gears are simple and not over-expensive, and at the same time are strong enough to insure safety in this vital part of the car.

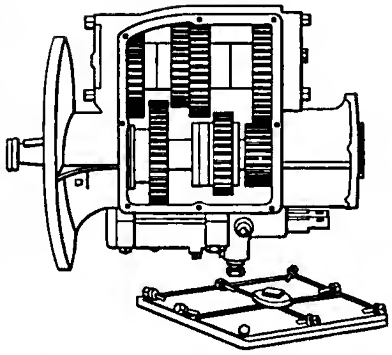


Selective gear and brake levers made by the Warner Mfg. Co.

"Imperial" compression couplings are shown at the exhibit of the Imperial Brass Mfg. Co., of Chicago, in a multiplicity of sizes and styles. They are of the cone type, and offer many advantages for automobile use.

Steel tool and battery boxes are the product of the Globe Machine & Stamping Company, of Cleveland. They are specialized for the various demands of an automobile, one being just the size to hold a gas tank; others are fitted with treads for steps.

The exhibit of the Elite Mfg. Co., of Ashland, O., is made up of various styles of "Ohio" jacks, the latest being a new-style ratchet, which is claimed to have only one-half the usual number of parts. The lifting bar can be dropped instantly.



Three-speed selective type of change-gear for rear axle unit construction.

Three distinct styles of "Long Distance" radiators are on the stand of the Long Mfg. Co., a Chicago firm which has attained prominence in this line. One of these is a vertical tube design, and the others are of the cellular persuasion.

McCord tubular radiators are seen in good company. The vertical tubes are closely united with the horizontal sheets which form the body of the radiating service, so that both form a rigid mass. The exhibit of the McCord Mfg. Co., a Detroiter, includes oilers, radiator fans and gaskets, all of which find a wide use among automobile manufacturers.

Auto Cle wrench sets appear on the stand of the Motor Parts Company, of Plainfield, N. J. These sets, which are well known to automobilists, consist of sockets of various sizes, all fitting a single universally-jointed handle, which can be operated through the most tangled maze of pipes.

The pioneer jack company, the Oliver Mfg. Co., of Chicago, shows its improved "Peerless" jacks, which are now made so that the handle can be used as a tire tool or a hammer. The jacks work with equal ease in either direction.

Sager equalizing coil springs, which are a form of shock absorber, form an interesting exhibit at the stand of J. H. Sager & Company, Rochester, N. Y., together with bumpers to protect the lamps and radiator.

Dust-proof and oil-tight, the Spicer universal joints shown by the Spicer Universal Joint Mfg. Co., of Plainfield, N. J., have found a wide employment on modern automobiles.

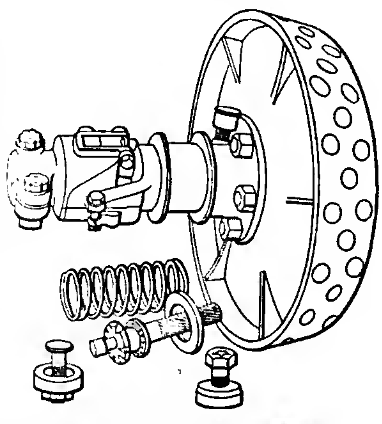
Rims of the suitable cross-section are one of the requisites in securing satisfactory tire service, so it is not likely that the up-to-date manufacturers neglected the stand of the Standard Welding Company, of Cleveland.

Whitney chains, made by the Whitney Mfg. Co., of Hartford, Conn., are especially adapted to commercial vehicle work, and the maker is vigorously pushing them in that line.

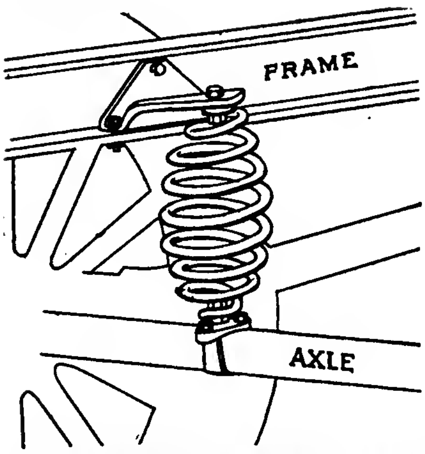
J. S. Bretz & Company, of New York, in addition to U. & H. magnetos, shows a full line of F. & S. ball-bearings, a German make which is widely used on both sides of the Atlantic. The bearings are made with single or double rows of balls, and also in a special type for magnetos for all purposes.

Standard roller bearings are shown both separately and combined in rear axles of various types, by the maker, the Standard Roller Bearing Company, of Philadelphia.

The Timken-Detroit Axle Company and the Timken Roller Bearing Company, of Canton, O., both show Timken roller bearings, separate and in axle forms. A specialty is the short type of bearing, which can be used in place



Cone clutch with cork inserts, product of the Auto Parts Mfg. Co.



Coil springs attached between the axle and frame, as used by Sager.

of the annual ball-bearings, and is made in the same sizes. This is finding much favor for change-gears, where the space is limited.

The Brown-Lipe Gear Company, of Syracuse, N. Y., shows a line of change-gears, steering gears and differentials which is familiar to all automobilists. Its spur and internal gear differentials have long been a standard.

"Continental" motors are shown three sizes, rated at 30, 50 and 60 horsepower, by the Continental Motor Mfg. Co., of Muskegon, Mich. All are four-cylinder models, with cylinders cast in pairs, and have a very neat pump system of lubrication.

Neat in appearance, the product of the Excelsior Motor & Mfg. Co., of Chicago, attracted favorable comment. It is a four-cylinder motor 4 1-8 by 5 1-4 inches, with a multiple-jet carbureter and a pump system of lubrication.

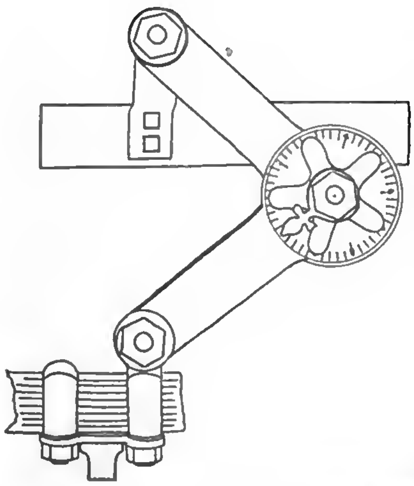
The Muncie Gear Works, of Muncie, Ind., shows a two-speed and reverse planetary gear in combination with bevels, differential, and a jackshaft suitable for use on motor buggies.

The Warner Mfg. Co., of Toledo, O., has a line of change-gears of all kinds, making a specialty of the rear axle type for unit construction. Differentials and steering gears are also shown. The Warner Gear Company, Muncie, Ind., is offering a full line of transmission gears, steering equipment, and parts. The plant of this company is one of the sights of Muncie, and many of the assemblers of automobiles of fine characteristics look to this concern for the very equipment which is at the bottom of the quality which is favorably commented upon.

Hartford shock absorbers of the friction-plate type are exemplified by two model automobiles each about two feet long, which seem to be traveling over a very rough road. One of them bumps and one does not; the conclusion is obvious.

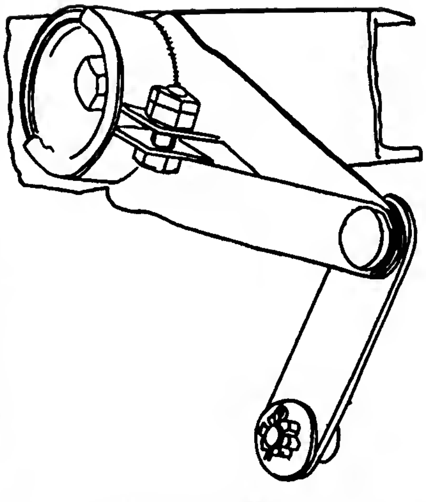
The H. & F. Mesinger Mfg. Co., of New York, has a combination strap and coil-spring shock absorber which has the merit of being simple and inexpensive. The company's inside blow-out patch is also shown.

Flat-leaf springs in both the customary types and in a patented form are exhibited by the Perfection Spring Company, of Cleveland, O. The patented form is a double semi-elliptic spring, with the ends connected by a special form of linkage.



Hartford friction-plate shock absorber, a pioneer in this line.

This company, in addition to its special product which is known as the Perfection Spring, is a large producer of every type of springs as used in the suspension of chassis frames. The plant is fitted out with all forms of heat-treating equipment, by means of which vanadium steel and the special forms of Krupp steel are made into springs such as are employed on some of the most exacting designs of cars which are now to be had. In a review of the spring and shock absorber situation as it obtains this year, it would be most incomplete without calling attention to the high character of the materials which are used in comparison with some of the products of even a year or two ago. When shock absorbers were first introduced, the idea was carried out in conjunction with most frail castings, insecure fittings, and methods sidering the situation as a whole.

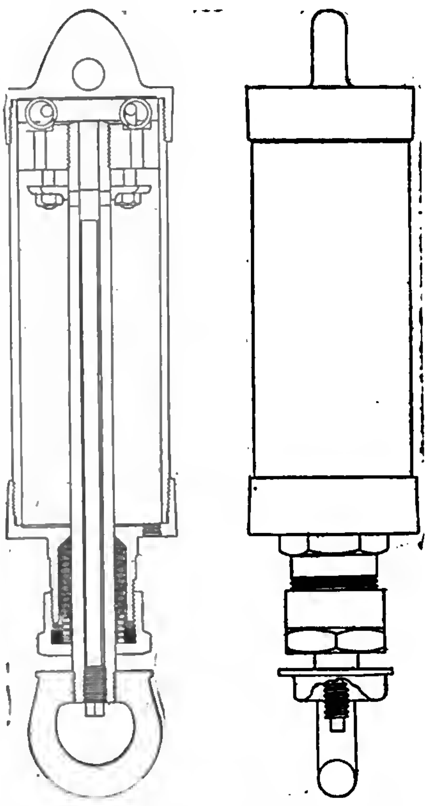


Friction-band shock absorber known under the trade name of Foster.

Ernest Flentje's glycerine-filled shock absorbers, hailing from Cambridge, Mass., are as usual much in evidence. They take the eye of the technical sharps, to whom the liquid compression principle is especially pleasing.

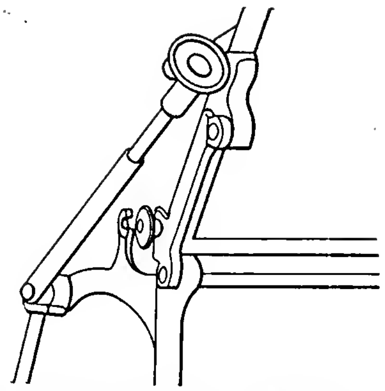
At this time, in a review of the situation as a whole, it is enough to say that the shock absorbers are well designed, materials used are capable and the methods of fastening to the side bars and to the axles are in keeping with the better understanding which accompanied experience. The principles which are employed in the designing of shock absorbers may be subdivided: (a) friction types, which set up a drag and dampen the oscillations of the moving mass (b) dash-pot types, which increase the dampening effect with the speed of acceleration of the moving mass, and (c) spring check types, in which the retarding influence is increased in proportion to the distance of travel.

Experience is the best teacher, hence discussions in relation to the relative merit of the respective types are likely to result in far-fetched conclusions, particularly when account is taken of the details in the application of the shock absorbers. It is very likely that failure is courted when any type of shock absorber is promiscuously applied, and it is undoubtedly true that the problem demands specific treatment in order that the particular applications will be in full accord with the especial requirements in every case. Many makers of automobiles realize that shock absorbers are capable of prolonging life of the members which make up a car.



Glycerine-filled cylinder with piston, the Flentje shock absorber.

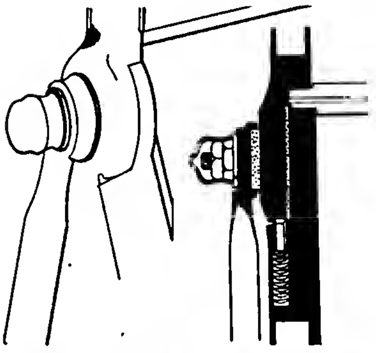
WIND SHIELDS



Locking device of Sprague windshield, with nut for upright position.

PROTECTION from wind and dust though scorned by the most hardened automobilists, is nevertheless essential to the comfort of many less accustomed to facing the wintry blasts. Modern windshields are designed to fit the appearance of the cars they are to be used on, and so are not the unsightly excrescences of former days, bristling with rods and knobs. Simplicity is now the keynote, and no great mechanical skill is required to change the shields from one position into another.

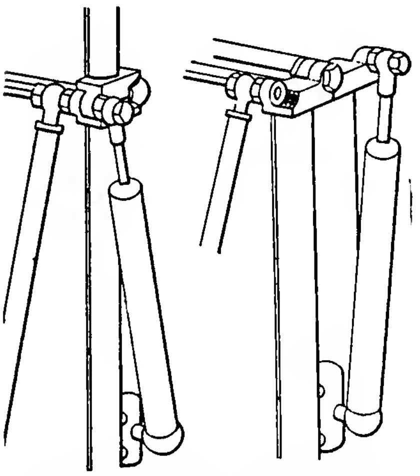
Eight or ten different styles of shields are marketed by the Chicago Wind Shield Company of Chicago, and these differ in many respects. One of these embodies very neatly the compound folding movement, which allows the upper half to move up and down very nearly parallel with the lower half, so as not to interfere with the steering wheel. When folded, it locks firmly both at the top and at the bottom.



Friction automatic windshield, with cross-section, showing leather discs.

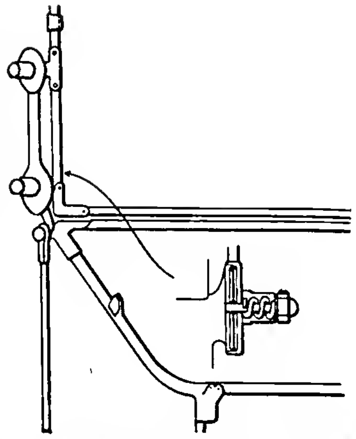
In the moderate-priced division the offering of the Fellwock Auto & Mfg. Co., of Evansville, Ind., is particularly notable. It is a divided shield, folding, and simple and neat in appearance. The frame is of wood, which will please those who like a substantial air. The design shows a desire to build a strong and reliable shield, without undue frills.

An automatic windshield, the upper half of which can be set at any desired angle, is marketed by the Garage Equipment Company, of Milwaukee, Wis. This feature is secured by a friction-plate hinge. T change the angle it is only necessary to loosen two wing nuts, one at each end of the hinge. The lower half can also be folded to the front, so that the whole shield can be swung down over the hood, out of the way.



Hydraulic windshield, made by Emil Grossman, New York.

Three automatic types are exhibited by C. A. Mezger, of New York. On the newer types retention is by a spring enclosed in a telescoping tube, 5 inches long and 3-4 inches in diameter. The spring works only when the upper half is within about two inches of either its upper or lower position; during the remainder of the swing the shield is prevented from moving rapidly by the friction between two smaller tubes enclosed in the large one. A third type is the friction automatic, which has no spring.

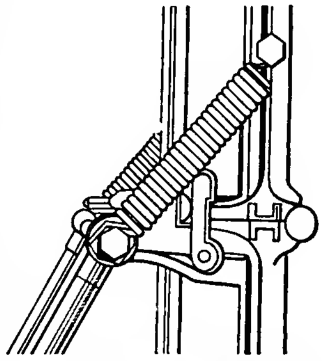


Troy windshield, showing the hinge giving parallel motion.

Sprague's tops and windshields, made by the Sprague Umbrella Company, of Norwalk, O., are shown in a number of interesting styles. In all of these it is evident that the object has been to secure a substantial construction which would stand the hard knocks a shield is sure to get. The locking devices are firm and free from complication.

The Sextette automatic windshield is shown by the Troy Carriage Sun Shade Company, of Troy, O. This shield is distinguished by the large number of graceful and convenient positions which it can be made to assume. The hinge contains two discs, one of them with a single corrugation, the other with two grooves, into which the corrugation fits. A spring forces the two discs together, thus locking the shield by the friction.

Noiselessness is claimed as the strong point of the Vanguard shield, made by the manufacturing company of the same name at Joliet, Ill. The shield is divided, with very narrow, almost invisible, brass molding along the edges. The hinge is a double-radius one, so that the upper half can swing without interfering with the steering wheel. The frame is of wood, of selected material, and the brass fittings are very substantial.

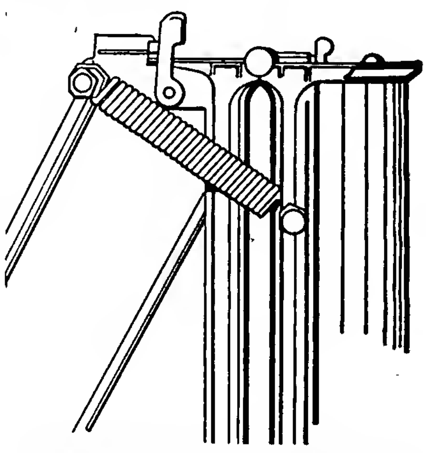


Standard automatic windshield (Mezger) in upright position.

"Vesco" windshields, as exhibited by the maker, the Vehicle Top & Supply Company, of St. Louis, show several models, all at reasonable prices which will bring them within the reach of the man of moderate means. Especial care has been taken to adapt these shields to the appearance of the cars on which they are to be used, with happy results.

The simultaneous activity of a number of inventors seems to have brought the windshield situation close to finality, for it is hard to see how a majority of the designs shown could be improved on. Complication has been reduced to the minimum, and appearance and construction are all that could be desired.

Noise, which emanated from wind shields, due to their poor construction, is now absent.



Standard automatic windshield folded, with the spring exposed.

Automobile Lubricants and Devices

THIS subject has proven to be the stumbling block of more ambitious writers than any other matter in connection with the running of an automobile unless it is that formula for approximating horse power of internal combustion motors has the lead by a neck. Nonsense creeps into lubricating discussions about as plentiful as sand floats into bearings, as it is borne on the breeze of passing automobiles, and, as a general rule, talk about the ills of the color or changing viscosity of lubricants, takes up so much space that there is none left to discuss the really important matters.

It is a little strange that an autoist of accentuated intelligence, due to a university education or the hammer blows of actual experience, will smear a little sand on the seat of a valve, grind for five minutes, and, by the simple process involved, take off 1-32-inch of the metal, bring the faces to an even bearing, make the valve tight under great pressure, and then claim that the lubricating oil used in the journal boxes of the motor and other parts is inferior, just because the same results are obtained, in about the same time, the only difference being that the bearings are ground in instead of the seats of the valves.

The ground glass, which is used in the valve-grinding process, differs but slightly from the silicon which creeps into the bearings, and even into the combustion chambers of the motor's cylinders, and, unfortunately, the grinding process, considering the bearings, goes on continuously; valve grinding, on the other hand, is an occasional process.

Even the blue above, referring to the sky, is due to dust—it is so fine we fail to see it excepting when a beam of light crosses the line of vision in such a way as to effect the end. A globule of water is so relatively large, when compared with a particle of dust, that the water would compare as the Sun of our Universe, alongside of the Moon which circles around Earth for the purpose of tolling off the thirteen months in an Indian's year. A bearing may be absolutely water tight and be wide open to dust-wear; due to the presence of this dust, is the same wear that makes it possible to grind in a valve.

The usual rule is, if a bearing squaks, give it a drink. The road to long life of a bearing is, do not let it squeak. Noise, while it denotes a condition of eminent danger, is also evidence of previous neglect. How much damage a bearing may have suffered before the noise became noticeable, is difficult of surmise, but it is safe to say that it is in the nature of permanent damage which no amount of "flooding" with oil, will eliminate.

When a golden eagle is coined at the mint of the Nation, and it takes wings of flight, if it rests for a time in the cavern of a man's pocket, jingling against a bunch of keys, it will not have to be given theroid tablets for the purpose of reducing its avoirdupois; it will be diminshed in intrinsic value by the contact, and, being money, the loss will be noticed and subtracted from its valve. When bearings are subjected to the same jingling process, as they will be if lubricant is not fed to them, they, too, will depreciate, and the loss will have to be counted in dollars.

WHAT IS THE PURPOSE IN OILING BEARINGS?

An academic statement of fact would read like this: "Oil forms a film over the bearings surfaces, floats the spindle, prevents the same from making contact with the bearing brasses, and, instead of the brasses wearing, the oil wears out instead—oil is cheaper than bearings."

If disappointment is to be avoided, if bearings are to last for long, and if depreciation is to be abandoned for the most part, it is necessary to assign to lubricants a sterner part. The first duty of a lubricant is to float the spindle and take the brunt of the work; to this must be added the duty of "sealing" up the journal sufficiently to exclude dust.

If there is a sufficiency of the lubricant present, that is to say, if there is a sufficient pressure behind it, and it feeds through the bearings, and out, it will, on its outward migration, float all the incoming dust, and this mischievous foreign matter, suspended in the stream of outgoing lubricant, will be prevented from making a mud pie under the spindle, where, if it is allowed to remain, it will grind the life out of the bearings.

Apparently, according to this reasoning, only liquid oil under pressure, is available for the purpose. The conclusion is ill-advised; grease is a most perfect seal for a bearing; it smears over the bearing surfaces adequately in view of the prime requirement, and the pressure which it sustains, acts as a pump, so that the excess exudes from the bearings, but, being thick and viscose, it remains around the rim, so to speak, most effectually blocking the way of any foreign substance which is knocking at the door for admittance.

There are one or two other points about solid lubricants which get mixed in the process of reasoning; some say it must be heated before it will enter bearings; they do not seem to understand that every bearing is capable of acting as a centrifugal pump. When any mass is rotated, it acts as a centrifugal pump, obeys all the laws of the same, and due to this the grease is pumped in, that is, pressure is accumulated, and the grease, in response to this pressure, follows the bent which we so aptly call pumping. Grease has one property which is to its advantage; if it is sluggish in its action during the process of pumping in, it is equally sluggish in its action after it gets in—it is likely to stay in.

Bearings, when they are cold, are less efficient than when they are warm; this is due to several phenomena:

(A) The amount of energy in the form of heat, which will be lost, will be in direct proportion to the difference in temperature between adjacent walls.

(B) The resistance to shear of the section of the lubricant will be greater as the viscosity of the lubricant is increased; viscosity increases as the temperature lowers.

The condition (A) is difficult of explanation; so long as there is no difference in temperature, it matters not at all as to the prevailing temperature, and yet, as has been definitely established, a cold bearing is less efficient than one which is working at a somewhat higher temperature.

There is one more point which will stand the light of calm discussion; all grades of lubricating oil come from the same well (barring differences in quality of crude oil from the different sections), and it is quite possible for a man of skill in the process, if he is provided with suitable facilities, to make all the grades of oil which can be evolved, and he must face a waste (as a by-product) unless he does utilize, in some way, the entire product of the well. Under the circumstances, and, in view of the basic considerations, it is almost futile for a rank outsider to discuss the respective brands of lubricating oil, for the purpose of fixing upon the quality; it is the skill of the man who does the work that lies at the bottom of the difference. Honesty of the distributor is a great factor, and a concern with a reputation at stake, has much to lose by substituting inferior goods—let us adore the oil-god who will be consistent rather than the fly-by-night who is insistent.

EXHIBITORS OF LUBRICANTS

Cook, Adam, Sons, New York.
Dixon, Joseph, Crucible Co., Jersey City, N. J.
Hancock Mfg. Co., Charlotte, Mich.
Harris, A. W., Oil Co., Providence, R. I.
Havoline Oil Co., New York.
McCord Mfg. Co., Detroit, Mich.
N. Y. & N. J. Lubricants Co., New York.
Randall-Faichney Co., Boston, Mass.

As the Guests and Hosts Appeared at the Eleventh Annual Banquet of the Automobile Club of America, January 31

CONSIDERABLE POLITICAL TALK AT A. C. A. BANQUET

THE Eleventh Annual Banquet of The Automobile Club of America of New York was held at the Waldorf-Astoria Monday evening, January 31st. It was unusually well attended, about 480 members and guests being present, divided into forty regular tables, besides the President's table and two press tables.

Miniature models of flying machines were suspended with pleasing effect above the tables.

The head table was honored by the presence of Hon. Elbert H. Gary, President of the Club; Rev. Wilton Merle Smith, D.D., Chaplain of the Club; Major-General Leonard Wood, U. S. A.; Hon. Lawrence Y. Sherman, Lieut.-Governor State of Illinois; Rear-Admiral Joseph B. Murdock, U. S. N.; Hon. Charles A. Towne, Ex-U. S. Senator from Minnesota; Col. John Jacob Astor; Hon. Archibald R. Watson, Corporation Counsel, New York City; Hon. J. B. R. Smith, Commissioner of Motor Vehicles, State of New Jersey; Hon. Frederick A. Bugher, First Deputy Police Commissioner, New York City; Hon. William F. Baker, Police Commissioner New York City; Hon. Warren W. Foster, Judge General Sessions, New York County; Hon. Martin J. Keogh, Justice Supreme Court, State of New York; Cortlandt Field Bishop; Hon. Martin W. Littleton; Hon. Charles F. Moore; Colgate Hoyt; Frederick D. Underwood; George F. Chamberlin; Glenn H. Curtiss; William C. Brown; William H. Page; E. Rand Hollander; Schuyler Skaats Wheeler, Albert R. Shattuck and Cornelius Vanderbilt.

After the usual Waldorf banquet menu had been served, President E. H. Gary introduced the following after-dinner program:

1. "Motive Power"—Hon. Lawrence Y. Sherman, Lieutenant-Governor of Illinois.
2. "The Effect of the Automobile on the Conscience, Pockets and Morals of the People"—Hon. Charles A. Towne, Ex-United States Senator from Minnesota.
3. "The Ideal Relation Between the Man Who Rides in an Automobile and the One Who Walks"—Hon. Martin W. Littleton.
4. "A Historian's Views as to the Future of the Automobile" —Hon. Charles F. Moore.

The Hon. Lawrence Y. Sherman, in the pose of a second Abraham Lincoln, announced his lack of knowledge of motor power, but was particularly well posted on general politics. He was followed by the Hon. Charles F. Moore, who was able to compare the political machine with an automobile in that both are given to inflation, free rides, and are started by a crank. His machine of the future will travel with equal facility on water, in the air or on land without roads. It was certainly a brilliant prophecy. The Hon. Martin W. Littleton disgressed on the increased cost of living, characterized the automobile as a sporadic device of the devil, and stated that the two he owns would not make one. The tables were badly deserted when the Hon. Charles A. Towne addressed the gathering, and at the close the impression was of an entertaining political meeting rather than an inspiration, following a great automobile event.

COBE AGAIN HEADS THE CHICAGO A. C.

Ira M. Cobe has been renominated for the sixth successive year for the presidency of the Chicago Automobile Club, of which he was one of the founders. It is expected that this nomination is equivalent to an election.

The administration ticket follows: For president, Ira M. Cobe; for first vice-president, T. N. Koehler; for second vice-president, T. J. Hyman; for secretary, C. A. McDonald; for treasurer, G. S. Whyte; for directors, F. W. Blocki, Claude Seymour, B. B. Johnson, Allan S. Ray, J. F. Gunther and Harry Vissering.

BUSY RACING SEASON FOR INDIANAPOLIS

E. A. Moross, director of contests at the Indianpolis Motor Speedway, announces the following racing dates as arranged for the Indianapolis track, these to be held under the sanction of the American Automobile Association: The track will be opened with a three-day meet on May 27, 28 and 30. May 30 is Decoration Day, and the races on this day will be under the direct auspices of the A. A. A. in the form of a national meet. The second event at the speedway is scheduled for July 1, 2 and 4. Oo August 3 and 4 the twenty-four-hour race will be held.

FORECAST OF ST. LOUIS SHOW

St. Louis, Mo., makers and dealers look forward to a very comprehensive show of motor cars which will be held in that city, February 14-19. Eighty-four makes of cars will be shown by 63 dealers or manufacturers, and several car loads of automobiles will be shipped direct from the Chicago Show.

The accessory dealers will swell the number of exhibitors to 76. The following cars will be exhibited: Moon, Dorris, Standard Six, Victor, Darby, Embree-McClean and Cunningham, all made in St. Louis; KisselKar, Cadillac, Peerless, Detroit Electric, Buick, Welch, E-M-F, Studebaker, Hupmobile, Regal, National, Lexington, Packard, Stevens-Duryea, Reo, Fal, Interstate, Maxwell, American, Simplex, Marmon, Oldsmobile, Oakland, Thomas, Chalmers, Hudson, Baker Electric, Atlas, Babcock, Stanley, Matheson, Corbin, Gaeth, Great Western, Rider-Lewis, Stoddard-Dayton, Studebaker Electric, Rauch and Lang Electric, Pierce-Arrow, Speedwell, Waverley Electric, Knox, Stearns, Brush, White Steam and Gas, Rambler, Parry, Paige-Detroit, Overland, Velie, Chadwick, Glide, Johnson, Columbus Electric, Firestone-Columbus, K-R-I-T, Winton Six, Jackson, Sterling, Apperson, Cartercar, De Tamble, Mitchell, Locomobile, Broc Electric, Westcott, Empire, Midland, Everitt, Springfield, Middleby, Smith Electric, Haynes, Pope-Hartford, Franklin.

NEWARK'S THIRD ANNUAL SHOW DETAILS

Newark, N. J., will hold its Third Annual Automobile Show during the week of February 19-26. It is said by those who know, that this show will compare favorably with greater shows held in New York and elsewhere. Newark, on account of its situation, is at once a part of the Metropolitan territory and is at the same time isolated from it. It is the center of the very prolific automobile section, and as such, much interest will be taken in the exhibition. One of the exceptionally interesting features at the show will be the exhibit of aeroplanes, which is promised will be the most complete one ever shown in America. This annual event which assumed large and important proportions last year, is looked forward to by Jersey enthusiasts with a great deal of pleasure, and this year it is expected that the local automobile agents will do a most thriving business, which is a matter involving some difficulties to explain due to the near presence of a host of New York agencies—citizens of New Jersey are patriotic.

INDIANA'S FIGURES SURPRISINGLY LARGE

The records of the Indiana Secretary of the State show that 72 new companies were organized in 1909, with an aggregate authorized capitalization of $6,533,000. All of this represents automobile and kindred industries. In addition, 16 sales agencies and garages incorporated, calling for an investment of $219,500. Seven new tire concerns came into existence during this year. The following companies increased their capital stock as follows: Overland Automobile Co., Indianapolis, $1,400,000; Planhard Manufacturing Co., Kokomo, $35,000; Simplex Motor Car Company, Mishawaka, $200,000; Western Motor Co., Logansport, $1,500,000; Auburn Automobile Company, Auburn, $725,000, and American Motor Car Sales Company, Indianapolis, $20,000.

GREAT PACIFIC COAST INVASION

California is coming into her own, so far as future racing events are concerned, and a number of important contests will be held this spring in the new Motordrome. Robertson announces that the Simplex people will build for him a light car somewhat along the Fiat "Cyclone" lines which he will also drive on the Coast. DePalma will be there with the original "Cyclone," while a third of this type, a Marmon 6-cylinder, is being built for Ray Harroun, of Chicago. Taking these in addition to other events, it will be seen that some of the usual speed battles of the spring will be fought on the Pacific Coast instead of over the old course as laid out on the sands of Florida.

TWO SHOWS FOR HARTFORD

Hartford will have two automobile shows, according to reports, instead of the one originally outlined. Neither one will run in opposition to the other. The local situation is a bit complex for the reason that no hall is available of sufficient size to accommodate would-be exhibitors. In consequence the second show, which is to run on the same date as the original exhibition, will be that of the Hartford Automobile Dealers' Association.

The Third Annual Show of the Hartford Automobile Dealers' Association from present indications bids well to outstrip all previous efforts of the organization. Fifty cars, representing 24 leading makes, are on the list, including some newcomers. The list of vehicles that will be on exhibition includes the Ford, Reo, Knox, Stevens-Duryea, Cadillac, Lozier, Waverly electric, Baker electric, Thomas, E. M. F., Flanders, Maxwell, Mitchell, Pierce-Arrow, Buick, Jackson, Rambler, Elmore, Cartercar, Interstate, Franklin, Empire, Hupmobile and McCue.

HARMONY SECURED IN CITY OF HOPS

Milwaukee, Wis., Jan. 29—The Milwaukee Automobile Club on Jan. 18 held a drawing for spaces at the second annual Milwaukee show, to be held in the new Auditorium from Feb. 22 to 27 inclusive. Dissension which marked the early campaign of the club for support among the dealers has almost disappeared, although there are still a few concerns determined to remain out of the show because they believe it more profitable to have private shows in their salesrooms, taking advantage of the interest aroused and crowds attracted by the big show.

ADDITIONAL EXHIBITORS AT BALTIMORE

Baltimore, Jan. 29—Fifteen belated dealers made such urgent demands for space at the coming Baltimore Show at the Fifth Regiment Armory, February 22 to 26, inclusive, after the first allotment of space had been made, that the show committee of the Automobile Club of Maryland had to rearrange plans to accommodate them. With the addition of this latest batch of exhibitors the number has been increased from 29 to 44.

A. A. A. TOUR FOR GLIDDEN TROPHY

At the meeting of the Contest Board of the American Automobile Association, held in New York, January 26, it was decided that the National Tour for 1910 should be a competition for the Glidden Trophy and that certificates to be known as "Glidden Certificates" should be issued to those contestants which finished the tour with scores that are within a small percentage of being perfect, the exact limits of such percentage to be determined and announced later.

The approximate date of the tour was set for June 15 to 30.

The tentative route outlined, embracing about 2,300 miles, is as follows:

Starting at Cincinnati, Ohio; thence to Louisville, Ky.; Nashville and Memphis, Tenn.; Little Rock and Texarkana, Ark.; Dallas, Texas, Okla City, Wichita and Topeka, Kan.; St. Joseph, Mo.; Des Moines, Cedar Rapids and Davenport, Iowa; Rock Island and Moline, Ill., and thence to Chicago.

SAVANNAH DISCUSSING GRAND PRIX

At a recent meeting of the Executive Committee of the Savannah Automobile Club plans were discussed for an international race to be held in Savannah on Thanksgiving day. At the meeting it was decided by those that attended to start work at once so that everything could be arranged in due time. Besides having an international race a stock car race will be had the preceding day, making the programme very similar to that of the Grand Prize race, held November, a year ago. Savannah is rapidly becoming an automobile center of the first importance in the South, and trade in cars is expanding considerably.

President Taft Rides in a Four-Cylinder Franklin

When the President rides out in an automobile, as he does frequently in contradistinction to his predecessor, the owner of the machine feels that he is signally honored, and hastens to chronicle the fact. Above our smiling executive is shown in the tonneau of a four-cylinder Franklin. The house is the Texas ranch house of Chas. P. Taft.

Spokane Taxicab Company has been reorganized with increased capital, and will begin operations with twenty high grade cars the latter part of February or early in March. Plans have been made for construction of a three-story garage, to cost $30,000, in the business district, and it will be rushed to completion. The new company, which has acquired the interests of C. E. McBroom, Robert H. Cosgrove and J. D. Williams, incorporated as the Spokane Taxicab Company, is composed of the following: W. G. Graves, Fred B. Grinnell, F. J. Holman, E. H. Knight, Clyde M. Graves, W. S. Norman, J. F. Carey, F. T. McCullough, Dr. R. McClure, Walter J. Nicholls, J. L. Prickett, D. B. Fotheringham, J. H. Spear, Dr. H. B. Luhn, Dr. S. B. Hopkins, George W. Merrill.

Louisville motorists have a fad which is growing rapidly. Unique emblems of every description, including Billikens, north poles, birds and beasts are being substituted for plain caps in front of their cars. Among the more popular emblems may be mentioned the north pole, while Prince Wells may be identified by a miniature facsimile of the road race cup which he won recently. Billy goats, monkies and eagles occupy prominent and somewhat exposed positions on the fronts of the radiators.

On January 13 the Michigan Lodge, National Association of Stationary Engineers, entertained one hundred engineers and mechanical experts from Detroit, Michigan and other cities, in the club rooms of the Michigan Steam Motor Company. Before the banquet those present inspected the new steam truck built by this concern. It is said that the engine in this type of truck is especially designed for general motive work where economy of space is desirable.

It is said that a number of motor trucks and business wagons in Louisville is about 20 per cent. more at this time than last year. The motor car has made steady inroads on the stronghold of the work horse and development along this line indicates the ultimate revolution of the old methods of handling goods, so far as the big cities are concerned.

The Automobile Club of Rochester is holding its second annual winter endurance run, having Syracuse as its objective point for the first night and return by another route to Rochester the second day. The Palmer-Singer 6-60 will be the pace-maker on the trip. This car has just completed its pathfinding trip made by Bert Van Tuyle, secretary of the Automobile Club.

It is said that Toledo, O., will get the Sterling vehicle plant, which proposes to manufacture a 1½ and a 3-ton truck. According to reports, the company, which is backed by Chicago men, and which has had several trucks manufactured, has practically closed negotiations for a site in Toledo. A. B. McCord will be the technical man at the head of the company.

Appreciating the valuable service rendered to the newspaper editors in Lancaster county, in their recent campaign for better country roads, the Lancaster Automobile Club has elected to honorary membership in the club each of the 30 editors within the domains of the county. It is said that this campaign has resulted in many road improvements in that locality.

In the American exposition which will be held in Berlin, Germany, during the months of June, July and August, a section has been set aside for the display of motor boats, engines and accessories. It is proposed to appoint an American committee to represent the motor boat industry of the United States.

The Asbury Park Automobile Company, of Asbury Park, N. J., has incorporated with a capital stock of $50,000. They will manufacture automobiles and conduct garages. The incorporators are: Daniel Havens, Fletcher T. Weedens, William C. Weeden and Louis P. Croce, all of Asbury Park.

The Motor Car Conveyance Company, New York City, has incorporated with a capital stock of $100,000. This concern will buy, sell and lease motor vehicles and taxicabs. The incorporators are: C. E. Lockwood, East Orange, N. J.; A. Lee, Brooklyn; J. W. Chapman, New York City.

Plans have been prepared for the Patent Holding & Mfg. Company to erect a four-story building for the manufacture of a commercial automobile to be designed by George E. Salzman, who will be superintendent of the plant. This company will also go into the garage business.

Bangor, Me., is to have an automobile show, to be held at the Auditorium from April 23 to 29, inclusive. This is the second annual exhibition in Bangor, and it is believed that there will be exhibited an even fuller line of cars and accessories this year than there was last.

The Owosso Motor Company, organized by a number of Owosso (Mich.) business men, will have a factory either in the latter town or in Detroit. They will manufacture a commercial car to sell for $1,850, rated at 20-horsepower. E. M. Clark is the general manager.

The Hartford, Conn., fire department wants a flying squadron to take the place of the horse-drawn chemical wagon. The board of fire commissioners, it is said, have in mind a Pope-Hartford machine. Five thousand dollars have been appropriated for the proposed purchase.

The Belnord Automobile Storage and Supply Company, New York, has incorporated with a capital stock of $10,000. They will deal in rubber tires and operate storage houses and garages. The incorporators are: I. Irving Cohn, Henry M. Flateau and Joseph Marx.

The J. J. Harper Company, Lynchburg, Va., has incorporated. The directors are: R. D. Apperson, president; L. G. Apperson, vice-president; G. O. Lee, secretary and treasurer. Capital stock, $25,000.

The date of the proposed All Connecticut Endurance Run has not yet been settled, and will not be until the A. A. A. takes action. It is said that this affair will take the form of an "automobile week" to include many other events.

Joerns Bros., of Stevens Point, Wis., with large interests at Sheboygan, Wis., and St. Paul, Minn., have organized a corporation with headquarters in St. Paul, to manufacture motor cars and trucks. C. A. Joerns, of Sheboygan, will be general manager.

The Post Lock Register Company has incorporated in New York City with a capital stock of $150,000. They will manufacture taxicabs and lock registers for the same. The incorporators are: T. W. Post, G. W. Moore, and C. Colgate, New York City.

It is reported that a corporation for the manufacture of motor cars will shortly be formed in Walton ,N. Y. E. B. Guild and George H. May have been appointed a committee to investigate the merits of different parts.

A midwinter endurance run from Hartford, Conn., to Pittsfield, Mass., thence to Springfield and back to Hartford has been proposed. On this same route traveled last year a Mitchell, driven by D. F. Smith, the local Mitchell agent, won out.

The Showalter Manufacturing Company, of Connorsville, Ind., has been incorporated with the following officers: President, T. H. Showalter; vice-president and general manager, H. G. Showalter; and treasurer, E. W. Showalter.

It is reported that the plans for the new Central Police Station and Criminal Courts Building at Milwaukee, Wis., to cost $250,000, will include a garage division for the care and maintenance of the cars owned by the city of Milwaukee.

The board of directors of the Motor and Accessories Manufacturers, Inc., will hold a meeting in Chicago February 10. W. M. Sweet, manager, with headquarters in New York, will spend several weeks in Chicago at that time.

Articles of incorporation have been filed by the Ellis-Tonnele Company, of Jersey City, N. J., with a capital stock of $50,000. They will deal in automobiles, supplies, parts, etc. Incorporators: A. L. Ellis, L. J. Tonnele and L. E. Herrman.

At the annual meeting of the Farmers' Mutual Insurance Company held at Lansing, Mich., the chief subject of discussion was automobile insurance, the association finally taking a stand against carrying automobiles as risks.

To the generosity of San Francisco motorists, enough cars were loaned to the children's agency of the Associated Charities to enable that organization to give 300 children an outing in Golden Gate Park.

The Co-Auto Motor Company, Indianapolis, has been incorporated with a capital stock of $25,000 and will manufacture and deal in automobiles. Incorporators: M. G. Beckner, J. Harrison and F. W. Wiese.

Application is shortly to be made for a charter for a new company in Philadelphia, to be known as the Lyman Tire & Rubber Company, which is to manufacture and deal in auto tires and appliances of all kinds.

The American Engine & Motor Company, of Wilmington, Del., has been incorporated with a capital stock of $1,000,000. They will manufacture rotary engines, automobiles, motor vehicle and power boats.

The Windsor Motor Company, Buffalo, N. Y., has been incorporated with $10,000 capital. The directors are: Henry M. Colgrove, Joseph Schmid, Jr., and Joseph J. Buettner.

The Milwaukee Chauffeurs' Club, recently organized at Milwaukee, Wis., has elected these officers: President, Marcus Wernicks; vice-president, Emil Krueger; secretary, J. A. Mayberry; treasurer, Michael Flynn.

The Omaha Automobile Show will be held from February 21 to 26, inclusive. It is expected that the leading manufacturers will be strongly represented therein.

It is said that over 100 carloads of automobiles were taken into Detroit for exhibition at the automobile show. Nearly 300 models of automobiles are exhibited.

The Maurer Garage Company, of Sheboygan, Wis., has been incorporated, with a capital stock of $15,000, by G. A. Franche, A. G. Maurer and F. G. Voigt.

OLDFIELD PURCHASES BENZ RACER

It is said that Barney Oldfield has purchased outright the new German Benz racing car in which Hemery made the world's record speed in England. This statement is said to come from Jesse Froehlich, managing director of the Benz Auto Import Company. He states that the car sold for $14,000 and that in the future Barney would have entire charge of it. This being true, the somewhat complicating rumors afloat concerning the probable pilot of this car may now be set at rest, as it is expected that Oldfield will drive the giant racer in all important contests.

George Ade, the Humorist, in His Mitchell Roadster

Even funny men ride in automobiles nowadays, as is evidenced by the picture above, which shows America's foremost witty man seated at the wheel of his small Mitchell roadster. In this little car Mr. Ade rides many miles in the course of a year, always finding the car "on the job."

In the early spring of 1896 Frank B. Stearns, then a young inventor of Cleveland, Ohio, produced one of the first "motor carriages" ever seen in Ohio. It was of the single-cylinder type, and although it was heir to all the troubles of the early type of automobiles, it is still in running order to-day. Single-cylinder cars were produced until the latter part of 1901, when the first 2-cylinder motor was produced. In it Mr. Stearns won a first-class certificate in the famous Mud-Lark run in 1904 from New York to Pittsburg. The growth of the Stearns factory has been noteworthy. The production has been steadily increasing, the output for the current season amounting to very close to 1,000 cars. With the extensive additions and improvements planned for the coming season, the output will be over the 1,500 mark. The number is equally divided between 15-30 and 30-60 models.

At the annual meeting of the B. F. Goodrich Company last week the directors decided to proceed with extensive factory additions early next Spring. The company has been adding two six-story buildings each year for the past two years. An appropriation of $1,000,000 was made for the additional improvements. The principal change in the official list came from the retirement of W. A. Folger as treasurer after spending 26 years in the rubber business. He is succeeded by W. A. Means, assistant treasurer; C. B. Raymond, secretary, was elected to the office of assistant treasurer. B. G. Work was re-elected president; F. H. Mason, vice-president; H. E. Raymond, second vice-president, and E. C. Shaw, general manager of works. The stockholders re-elected the old board of directors.

At a recent meeting held in New York, various officials of the Lozier Motor Car Company discussed the matter of length of service of many of the employees. It was noted that during their bicycle days this company gathered together a very strong working force and carried it practically into the motor business. Among those holding records for long service may be mentioned J. D. Perrin, the engineer of the company, with eighteen years to his credit; Samuel Roger, treasurer, started twenty years ago as an office boy; C. A. Emise, sales manager, has been with the Lozier company for seventeen years, and E. C. Cleary has had a service of thirteen years.

B. G. Vreeland, president of the Vreeland Bros. Automobile Company, Denver distributors of Moon cars, left St. Louis for home Tuesday, after a week at the Moon factory. Coming direct to St. Louis from the New York shows, Mr. Vreeland stopped at St. Louis to familiarize himself with the Moon construction. To do this he took off his coat, donned machinist's overalls, and with one of the factory engineers went over the various processes of manufacture and assembly. He said, when leaving the city, that he thought more of Moon cars than ever after his mechanical tuition.

The Allis-Chalmers Company, of Milwaukee, is shipping out each day large orders for electrical apparatus to motor car manufacturers, including E. M. F. Co., Detroit, Mich.; Oak Park Power Co., Flint, Mich., auxiliary of the General Motors Co. of Flint, Mich.; Kelsey-Herbert Wheel Co., Detroit; Rapid Motor Vehicle Co., Pontiac, Mich.; American Motor Castings Co., Brush Runabout Co., Detroit. Factory cost is reduced to a considerable extent by the motor-drive system, and has already resulted in reductions in wholesale prices for manufactured articles.

The Flint Auto Top Company, of Flint, Mich., organized and incorporated last week for the purpose of manufacturing automobile and launch tops. It is capitalized at $10,000, with the following officers: M. L. Dyer, president; S. D. Bolton, vice-president; C. A. Fot, secretary and treasurer; A. W. Myers, superintendent, with temporary offices and factory at 1104 North Saginaw street, allowing a daily output of from 75 to 100 tops. Within the course of 60 days they will be able to triple their capacity, as their new factory will be ready for occupancy by that time.

A number of changes have taken place in Hartford, Conn., local selling field. S. C. Hutchinson has succeeded Robert R. Ashwell as the head of the Franklin agency. Russell Faber, who recently acquired the Reo, has also taken on the Knox. George B. Knox, the Peerless representative, will handle the Hudson. Alexander Smith has given up the Regal. E. H. Harris will succeed A. W. Peard as agent for the Overland. The Hupmobile and Everitt 30 are represented by C. K. Hanson. All the local agencies report very bright prospects and many immediate sales.

J. C. Zimmerman, of the Green Bay (Wis.) Motor Car Company, which recently succeeded to the business of the motor car department of Gottfredson Bros. Co., wholesale hardware, has sold his interest to W. H. St. John, of Oshkosh, Wis., and will retire. H. J. Malchow, who, with Mr. Zimmerman, organized the Green Bay concern, remains. The company's garage on North Jefferson street has recently been enlarged to nearly twice its former capacity, and 60 cars can be handled with ease. The repair shop has been made a feature.

As an instance with which the Diamond quick detachable demountable rim can be handled it is but necessary to say that during the Madison Square show this device was demonstrated to a prospective buyer who, after making inquiry concerning its points, said that while the rim was being demonstrated it was removed and applied no less than a dozen times and apparently with the same ease with which a man takes his watch from his pocket and puts it back.

Recent consular records from all sections of the globe indicate a slow but sure increase of imports of American cars into foreign countries. The Royal Tourist car company is making bids for business in this field in a conservative but effective way. As an instance of this it may be cited that Clifford W. Fuller, secretary of the Royal Tourist company, and K. V. Painter, a stockholder, are carrying the Royal propaganda into South Africa.

The Ohio shaft-drive electric, manufactured by the Ohio Electric Car Co., of Toledo, Ohio, has placed three new agencies: In Denver, with the Mathewson Automobile Co., 1624 Broadway street; in Louisville, Ky., with the Dunham Automobile Co., 444 South Third street, and in St. Louis, with the Smith Automobile & Battery Co., 5027 Delmar Boulevard. This new electric is the only shaft-driven automobile ever made without a universal joint.

The Colonial Tire and Rubber Company, which controls the Firestone tires in Europe, has declared a 10 per cent. dividend, and elected F. S. Lahm, the noted aeronaut of Paris, as president; J. A. Swinehart, vice-president; P. D. Hall, secretary and treasurer. The other directors are William Byrider, John Byrider and Frank E. Whittemore. The Firestone patents in America were originally owned by J. A. Swinehart, who recently returned from Europe.

The Penn Motor Car Co., of Philadelphia, entertained all of the sales managers throughout the State of Pennsylvania, as well as the officials of the Mitchell car as its guests, at a banquet at the Hotel Walton in that city. A. B. Berrian, of Racine, Wis., representing the factory end of the company, and Charles B. Skinner, the New York manager, was present as the Eastern delegate. More than eighty guests were present.

The Wilcox rubber plant at Mansfield, Ohio, headed by F. A. Wilcox, of Akron, suffered a $16,000 loss last week on account of fire. The company manufactures tires. At the annual election officers were elected as follows: President, F. A. Wilcox; vice-president, C. H. Walters; treasurer, F. M. Bushnell; secretary, F. W. Walters; these, with C. R. Grant, Dr. James E. Waite and Dr. R. C. Kinnaman constituting the directors.

The Holbrook-Armstrong Manufacturing Company of Racine, Wis., is perfecting a new type of four-cylinder motor, which, it is reported on reliable authority, will be used exclusively by the Racine-Sattley Company for the production of gasoline cars and trucks. The Holbrook-Armstrong Company is said to have contracts for delivery of its motor to the Sattley concern beginning in 30 days.

The Yeomans Body and Box Company, of Detroit, will make an extensive addition to their plant. This is made necessary by the growing requirements of automobile manufacturers. The board of directors of the company are: Arthur Yeomans, president; Albert Fritzsche, vice-president; Fred H. Yeomans, secretary and treasurer, and John T. Lombard.

With W. C. Durant, general manager of the Buick Company in Flint, Mich., as host, a large party filling a special train of 12 cars journeyed from Detroit to Flint, where a complete inspection of the Buick plant was made. Some idea may be had of the size of this institution when it is stated that the Buick payroll exceeds $192,000 every two weeks.

Lang & Scharman, agents for the Maxwell at Marshfield, Wis., have produced a "sleighmobile" by remodeling a Maxwell runabout into a sleigh. The front wheels have been removed and replaced with runners, while heavy anti-skid chains have been attached to the rear tires. The contrivance makes excellent speed on snow-covered roads.

Entire K-R-I-T product for 1910 has been sold, its final agencies having been closed several days ago. Three hundred and twenty-five cars were allotted to Cleveland, Buffalo and San Francisco, and the entire output of the company, 1,000 cars, has already been taken care of. It is said that the demand was much larger than the supply.

The Sheldon Axle Company, of Wilkes-Barre, Pa., for thirty years makers of axles, have for seven years been making commercial automobile axles and it is said that during this time they have never lost a customer and have built the largest factory of its kind in the world.

Goodrich tires were well represented in the two New York shows. Out of fourteen makes of tires represented at the Madison Square Garden show, the Goodrich had a natural representation. In Detroit also this tire had a very large representation, especiallv on the high-priced cars.

The story which has been circulated to the effect that the Chalmers-Detroit Motor Company is interested in the building plans of the Hudson Motor Car Company was denied by Chalmers-Detroit by wire just as The Automobile was going to press—particulars not available.

It is stated that more than eight thousand Franklin air-cooled motor cars are now in use, the total of shipments from the factory in Syracuse having passed that number a few days ago. The Franklin is making some splendid road and hill records in the far West.

Realizing chain defects as they exist under unfavorable road conditions, the Baker Motor Vehicle Company, after experimenting with various types of transmissions, has announced that all their 1910 models will be equipped with bevel gear shaft drive.

Bacon's Garage Co., Inc., of Hackensack, N. J., are the Bergen County agents for the Mercer Car, and represent locally the E. M. F. and Flanders and Buick. James Bacon is president and Ralph D. Early is secretary and treasurer.

The Brown Automobile Company has taken the agency for the sale of National cars in Louisville, Ky., and New Albany, Ind. The Velie will be represented in Louisville by the Dunham Automobile Company.

The Ajax-Grieb Rubber Company, of New York, has issued a very pretentious and handsome calendar, ingeniously contrived, and embracing a distinct novelty. It is much appreciated by the trade.

PERSONAL TRADE MENTION

"Bud" Moran, who recently became manager of the Craig Auto Company, of Detroit, will handle the output of the new Abbott Motor Company in Michigan. John B. Philip, formerly with the Chalmers-Detroit Motor Company, is in charge of the Abbott factory, and with perfect organization this concern promises prompt delivery.

Gordon MacGregor, in charge of the Canadian interests of the Ford Motor Co., has just completed a trip around the world in the interests of the company. Mr. MacGregor left Watervliet, Canada, in the middle of August, and has since then traveled 140,000 miles.

Jack Barnes, for three years a well-known mechanician, and more recently a driver of racing cars, has accepted the position of superintendent of the Delavan Lake Boat and Engine Company. The company operates a large shop for motor car repairs and has a garage.

W. N. Booth, for several years connected with the sales department of the Olds-Oakland Company, Cleveland, has invented a demountable rim, and has organized the Booth Demountable Rim Company to manufacture it.

A. A. Grimes, formerly connected with the sales department of the Cleveland, Ohio, branch of the Warner Instrument Company, has accepted a position as sales manager of the Cleveland Speed Indicator Company.

R. Harry Croninger has assumed the management of the American Locomobile's plant at Providence. He was formerly connected with the Pennsylvania Auto Motor Co., at Bryn Mawr, Pa.

B. T. Strickland, of Fitzgerald, Ga., has sold his garage and will open an automobile livery.

H. S. Larzelere will be in charge of the Chadwick exhibit at the Chicago Show.

THE AUTOMOBILE

PUTTING an estimate on the attendance at the Coliseum during the opening time would be fully as inaccurate as many of the wild estimates which are now being made for the purpose of disclosing the extent of the automobile industry. The Coliseum, the Coliseum Annex and the First Regiment Armory were jammed to a state of suffocating congestion by an audience which by its dress and tone disclosed the presence of Chicago's four hundred, flanked by the Old Guard of autoists from all the automobile centers of America, with a fairly good presentation of the foreign contingent. The daily attendance after the opening has been fully up to the comfortable capacity of the entire space afforded, and that the audience has been entertained, as well as interested in the cars and accessories which were exhibited, was proven in a hundred ways.

Henry Thiede, the artist, whom Manager Miles placed in charge of the decorative scheme while he treated the Coliseum as the heart of the show and put forth his best effort there, he, nevertheless, made much of the Annex, the Armory and even the basement received a quota in the distribution of the decorative idea. In order to appreciate best the scheme of decoration it is necessary to visit the Coliseum, which, when properly described, would compare most favorably with any one of the many beautiful park scenes which abound in the metropolis of the West. The oak trees from Wilmette and the vicinity along the north shore were in a double line, towering above the exhibitions, reaching to the blue of the dome of the building, and the deception was carried to a fitting conclusion by the nature-faking way that stumps and roots, shrubs and moss were scattered about after a fashion, carelessly. Beneath all this haphaz-

ard imitation of nature's handiwork, the trees, which were very large in some instances were anchored to the floor and structure most securely by proper bracing and irons, so that the safety of the public was cared for.

Expressions of satisfaction were in evidence at every hand, due to the excellent manner in which Manager Miles took care of the automobile contingent, somewhat, it is true, to the detriment of the accessory exhibitors, although there were so many applicants for space that it was simply beyond the range of possibility to care for the close approach to 200 of them who were left out. Under the circumstances it was a wise move to afford space to the car exhibitors and to improvise for accessory makers to the greatest possible extent. The 89,000 square feet of floor space available, having been used to the best advantage, was bound to terminate the effort of Manager Miles, and those who failed to draw the lucky number had but the one expedient to fall back upon, *i. e.*, an outside nearby exhibition.

In a few instances car makers preferred to exhibit their wares outside of the big show, and notably the Ford Motor Company. Its policy is to exhibit at the New York Show only. The Ford branch in Chicago is turned into a showroom and, while it is in a relatively small way, it is putting up excellent op-

E—Buick exhibit, showing a bared chassis, and several examples of this make as a setting for the chassis.

F—Premier exhibit guarding the gate in a setting with a big tree to mark the place.

position to the Coliseum. Velie does not favor shows, and his company is keeping "open house" at the Chicago branch. Including the above-named companies there are 28 makes of automobiles which are being exhibited in branches outside of the show, 10 of which were not present at any of the big shows this year. They are: Davis, Cino, Enger, Westcott, Continental and Henry in the pleasure class; Schmidt and Duntley in the commercial line, with the Ohio and Ideal in the electrics.

Of the remaining cars which were unable to draw space, the following will be mentioned: Anhut, Panhard, Firestone Columbus, Simplex, Standard, Palmer-Singer, Isotta, Randolph, Saurer truck, Demot and Middleby. A number of the accessory makers also put up private exhibitions, among which is Michelin, with an elaborate window show; and in the new building of the Simons Hardware Company at the northwest corner of Michigan avenue and Fourteenth street, activity is rife, space having been leased to a half dozen concerns of prominence, including Anhut, DeTamble, Grout, Westcott, Continental, Paterson and Henry. At 1233 Michigan avenue Davis and Enger have taken space with Cornish and Friedburg, who handle the Schacht. In the Regal store at 1502 Michigan avenue the Duntley truck and the Cino pleasure car are shown.

CLOSELY examining the automobiles at the Ninth Annual National Show discloses many points which must impress the autoist of experience, some of which will surely appeal to designers as requiring slight attention in the long run, although the situation, from the user's point of view, is on such a high plane that criticism becomes extremely difficult, and for the most part unprofitable. This being the third large show within a few weeks, it has enabled spectators of acumen to reach conclusions of a more or less definite character bearing on the industry, with the idea of noting advances made, and the time is ripe to handle the subject on a basis of cold judgment, rather than to evade such of the facts as may be disconcerting.

With 81 makes of gasoline pleasure cars lined up for inspection, eight makes of electrics and nine separate makes of commercials on the flank of the pleasure automobiles, it is possible to go down the line and note just what the differences are. The first glance is enough to indicate to even a casual observer that there are many divergences. Some of the ideas are accounted for by circumstances, more by point of view, and, for the rest, they present evidences of differences of opinion of designers.

That there should be several schools of designers is to be accepted as a matter of fact, and in making comparisons it is necessary to differentiate as between the schools. Within a given school of design it does seem as if there should be a certain uniformity, and the few divergences from standard methods within schools are not so prominent as to defeat the main contention, i. e., the general situation is thoroughly healthy, and autoists, if they exercise a little care in making selections, should be rewarded by automobiles which will come up to all reasonable requirements in actual hard service.

SELECTION IS PUZZLING IN THE FACE OF NUMBERS

A count of the separate automobiles which are on exhibit discloses the presence of 266 different models, and this very fact adds to the difficulty which a man of even a fair amount of skill would experience in attempting to select the best automobile for him. The very fact that there are so many selections, each one differing from the next in some important particular, is proof positive that there is a demand for each.

It is on this account that a prospective purchaser is justified in consulting his requirement, rather than to be guided by the arguments of the salesman; it makes no difference what the salesman has to say if the automobile which he has to offer is not designed to do the work which must be performed. Satisfaction is not bound up in the style of a particular automobile in comparison with the modest bearing of the one next to it. If a prospective owner is to act as his own chauffeur, for illustration, provided he is not a mechanic, it stands to reason that he will want an automobile of the greatest simplicity, one which is get-at-able in all particulars, and sturdy rather than stylish.

Much power means fast going, many chances of damage in the hands of men of little or no skill, and, it is the height of fallacy for a purchaser to make such a

Presenting decorations, the iron fence and ornamental gate to the rear of the Packard exhibit, and Packard cars guarding the gate. The make is too well known for comment.

selection. A repair bill, when it is footed up at the end of the year, is bound to reflect the speed which the car may attain, on the ground that the energy which may be stored when a car is running on the road, is proportional to the weight on the one hand, and to the velocity squared on the other.

NEW MODELS STUDIED BY SPECTATORS WITH INTEREST

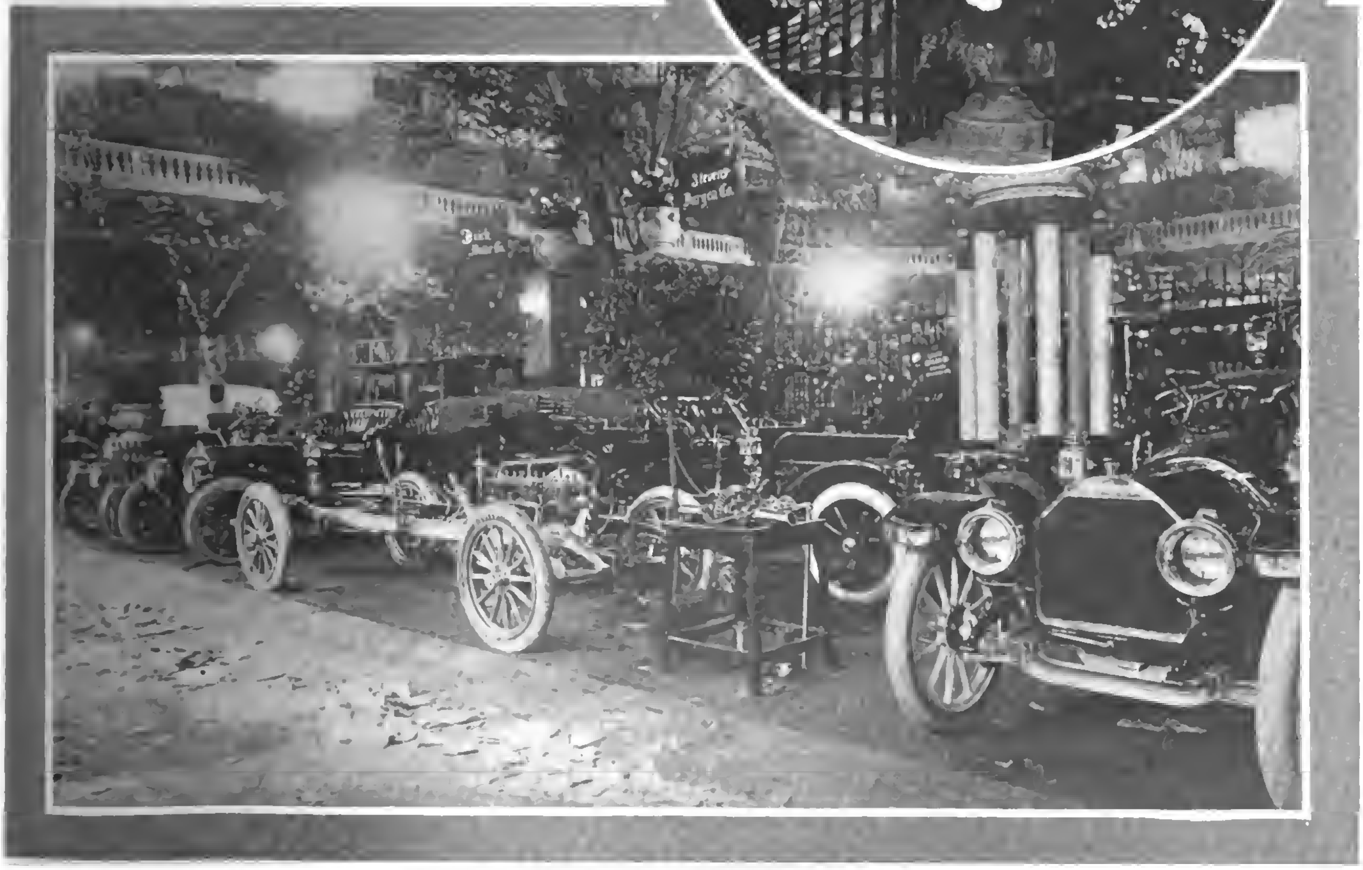
Before discussing the phases of the cars as shown, it will be profitable to understand that the new models (those which came out this year) would naturally have to be considered separately, if they represent radical differences in point of design from cars which were previously reduced to a settled plan. It is for this reason, perhaps, that spectators exhibit rare curiosity as they gather around the displays of the companies which have the most recent origin. The particular cars of the 266 shown which are less than a year old include Flanders, Hudson, Everitt, Ohio, Clark, Fuller, Cole, Lexington, Lion, Metz, Monitor and Springfield.

The Everitt probably represents an entirely new school of design; it differs from all other automobiles thus far offered due to the design of the motor, in which the cylinders are not only cast en bloc, but they are integral with the top half of the crankbox. This motor, beyond this fundamental difference, has some features which were brought out abroad, among which is the practice of casting the inlet and exhaust manifolds integral with the cylinders, thus making the exterior perfectly smooth, and reducing the whole process to one of coring in the foundry. One of the advantages obtained lies in the transfer of heat in the mixture, as it is transferred from the carbureter, so that the liquid gasoline, in spray form, is afforded sufficient heat.

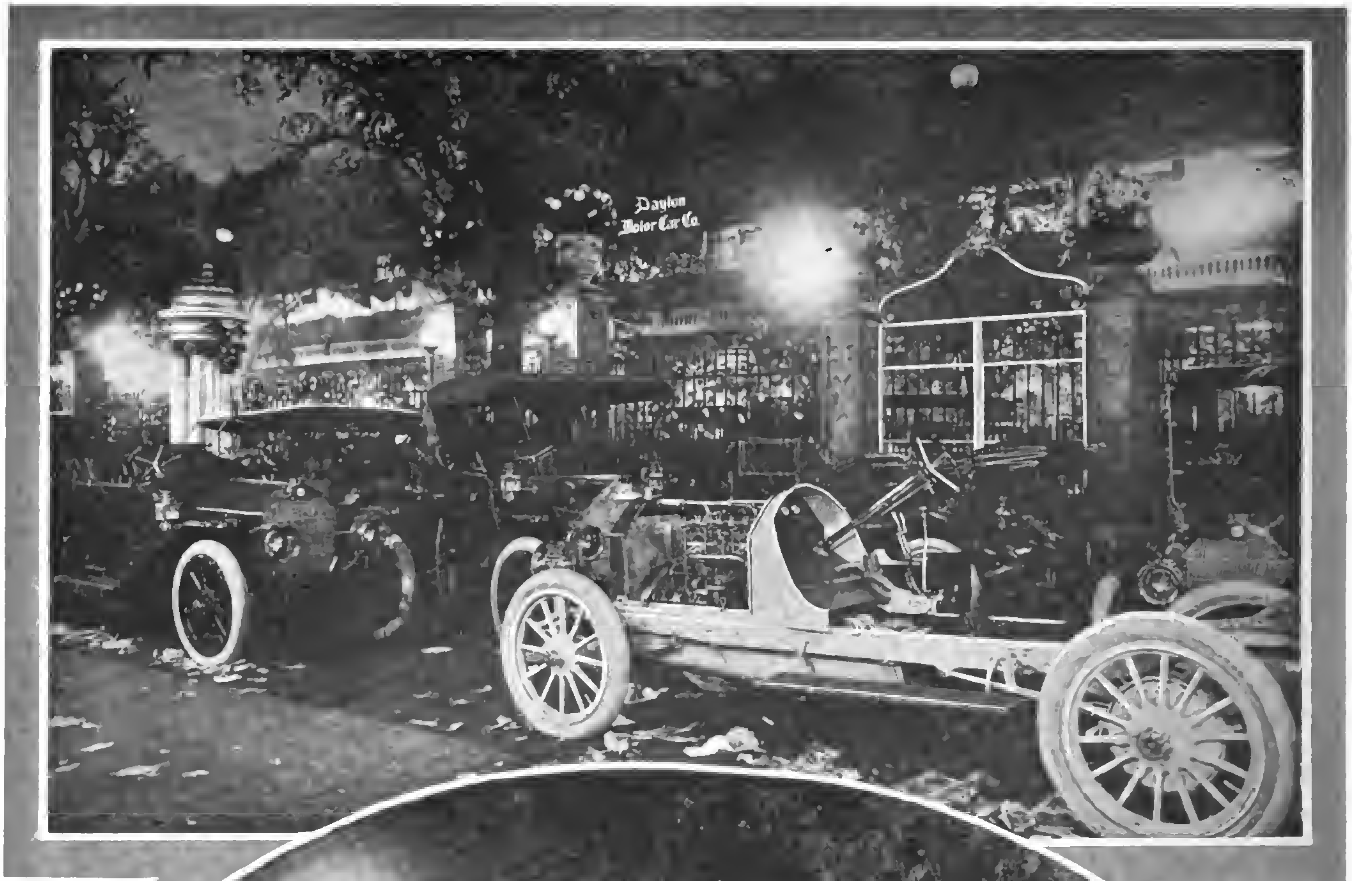
There is one other important deviation this year as compared with the practice which obtained a year ago. High-wheeled types of cars are on the wane, and among the former makers who confined their efforts to high-wheeled work, the following came into the National Show with conventional types of automobiles:

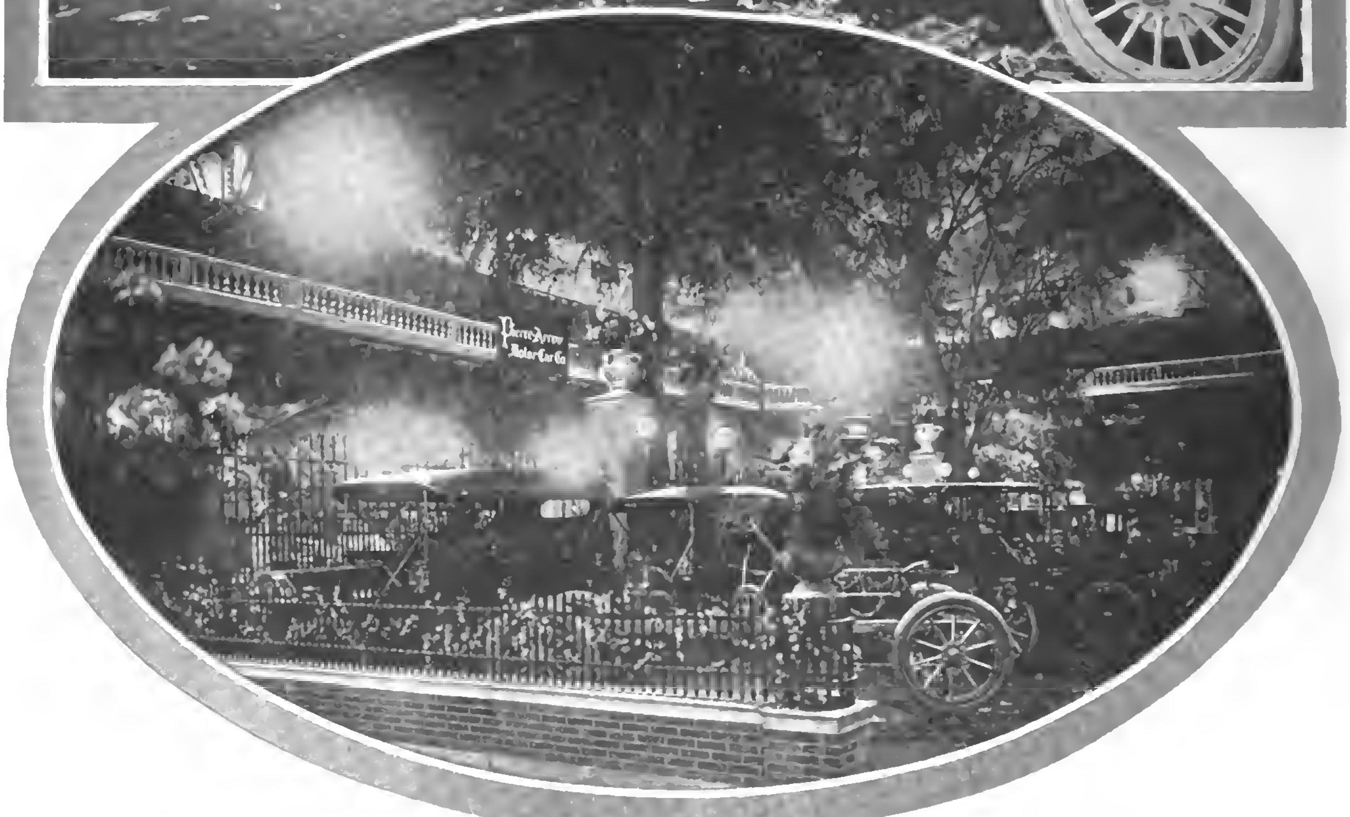
McIntyre, Staver, Black, Fuller, Schacht, Zimmerman, and Richmond. The failure of the Holsman Automobile Company, which went into the hands of a receiver after it applied for space in the National Show, will have a marked dampening effect on the high-wheeled situation, since this concern was the pioneer in high wheel work, and despite the large number of cars put out and their performance, the end does not seem to be promising.

Visitors to the Chicago Show will encounter a number of makes of cars which were not exhibited at either of the two big shows in New York, and they will add something of interest. Some of these cars are very well known to the automobile fraternity, and but few of them are so new as to be wholly unknown to the casual visitor. These cars include Rambler, R. A. C., Auburn, Austin, Berliet, Dorris, Richmond, Lexington, Great Western, Springfield, Rider-Lewis, Fuller, Monitor, Clark, Diamond T, and Zimmerman. In addition to the Berliet, Fiat and Renault were in the foreign contingent, which made up in quality what seemed to be lacking in quantity.



Presenting the exhibition of the Stevens-Duryea, showing a chassis in the foreground, details of the differential on a stand, and touring cars to the flank and rear.





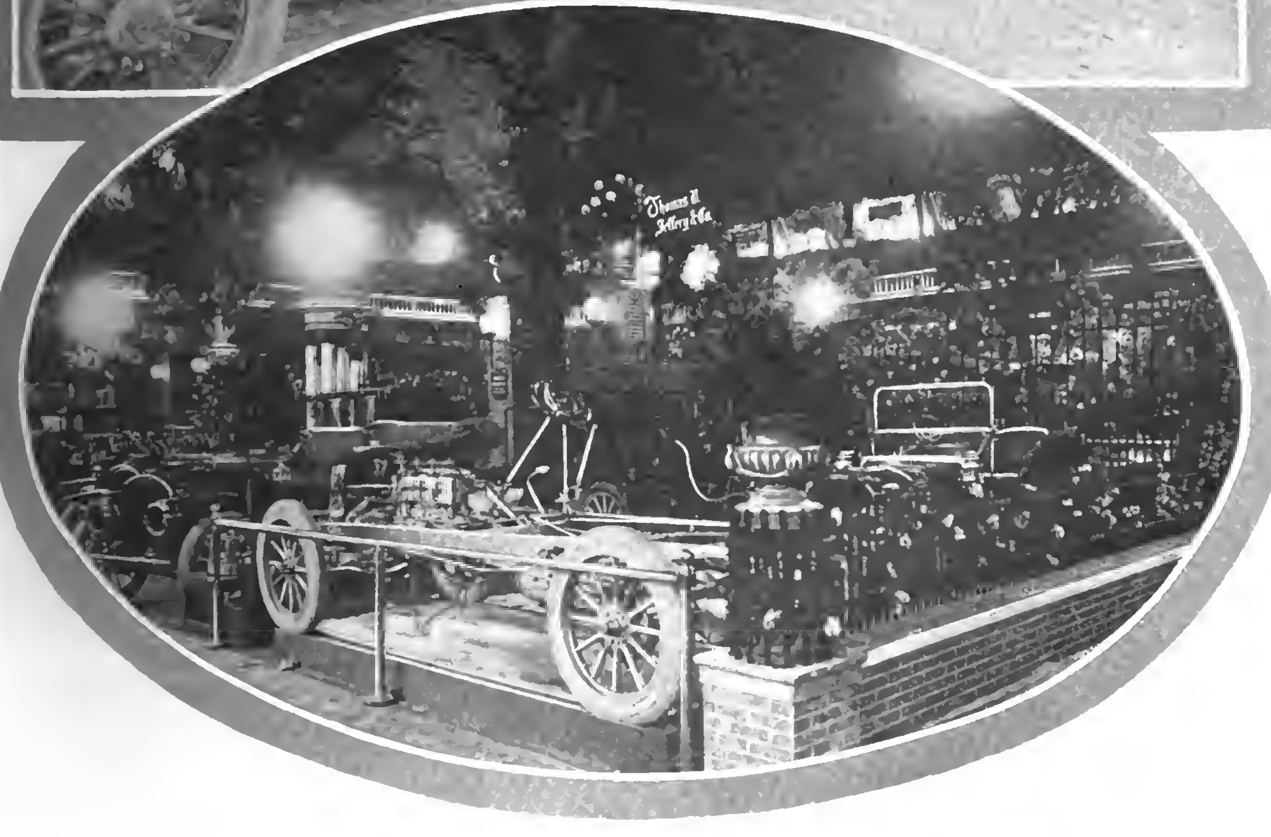
At the top, presenting the background for the exhibition of Stoddard-Dayton cars, showing a bare chassis in front, and several types of touring cars to the flank and rear.

At the bottom, presenting the Pierce-Arrow exhibition, which includes a "Six" chassis, touring car with cape top, and a limousine to the right.

INFLUENCE OF THE PATENT SITUATION ON THE FUTURE

Before this discussion, which has for its basis the types of automobiles as they are to-day, with a reflection of the future, it may be a point in favor of accuracy to take up the patent situation and discuss its merits. When Judge Hough rendered the decision to the effect that the Selden patent was valid, he put into the hands of the A. L. A. M. a lever which has already rendered it unnecessary for the A. M. C. M. A. to exist. This condition not only eliminates the A. M. C. M. A., which is about to be dissolved, but it bands together the great majority of makers of automobiles in this country, gives them the advantage of stability, in the absence of ruinous competition, and will have its bearing in the direction of standardization in the future.

In the past ideas, merely because they were different, were

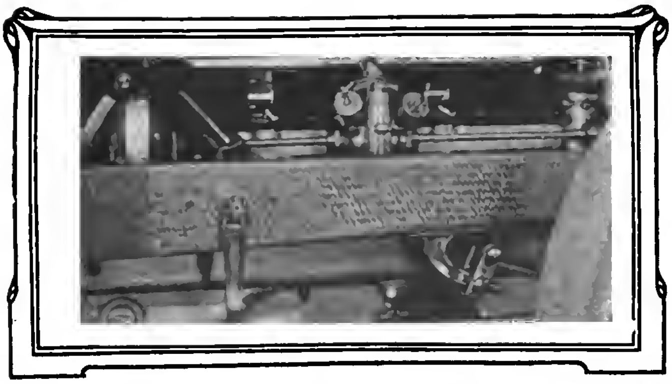


At the top, depicting the central figure of the scheme of decoration, and the Peerless exhibition in the foreground, numbering among its fine examples a bare chassis and types of enclosed cars.

At the bottom, exhibition of the Thomas B. Jeffery Company, presenting a Rambler chassis in the foreground, and other examples of Rambler cars surrounding.

looked upon as novel, and they were adopted by the respective companies in star-chamber session, and sprung upon an unsuspecting public at the shows. In many cases these ideas were half baked; in some instances they were tried out just enough to discover that they had the germ of practicability, without being sure that the factor called service efficiency resided within them sufficiently to take notice of.

While it is highly improbable that the automobiles which are now to be seen represent finality, the fact remains that they do represent a high degree of stability, are rational in their inception, and carry out the intent of the makers so thoroughly well that a user, if he selects the automobile in view [illegible] is real wants, will have no legitimate grounds for compl[illegible]atisfaction is now more of a certainty than an [illegible]



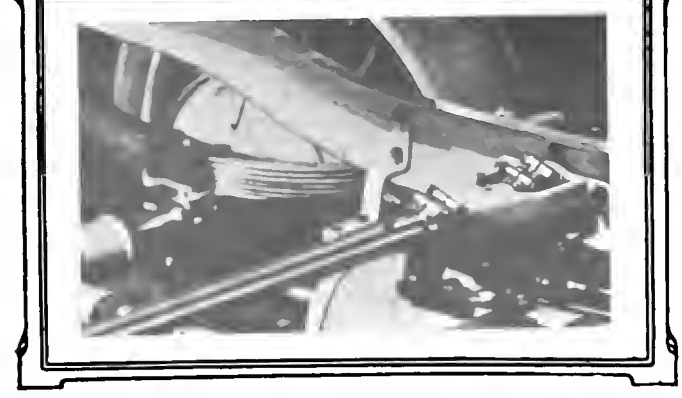
Oldsmobile, showing the steering arm and the spindle which projects through the chassis frame, also the front spring shackle.

BODY WORK SEEMS TO BE RAPIDLY CRYSTALLIZING

The influence of the carriage makers' art left its mark on the automobile, which has only been erased after several years of consistent advance, but last year, when straight-line effects were brought into prominence, it was then said that the body situation was adequately cared for. Torpedo types of bodies, which rather suddenly presented themselves almost at the show, before they were definitely known to obtain in this country, are not only promising, but they upset all earlier prediction. These bodies are more nearly in accord with the locomotive idea than anything which was heretofore presented, and that the automobile is properly classed as related to the locomotive rather than the horse, is a point which will scarcely require bolstering up. The word "locomotive" is used here in the sense that it distinguishes as between a self-propelled kinetic machine and a horse-drawn vehicle. The character of the stresses which are set up in the kinetic machine are entirely at variance with those which obtain when a vehicle is drawn.

WOODEN WHEELS ARE PREFERRED IN AMERICA

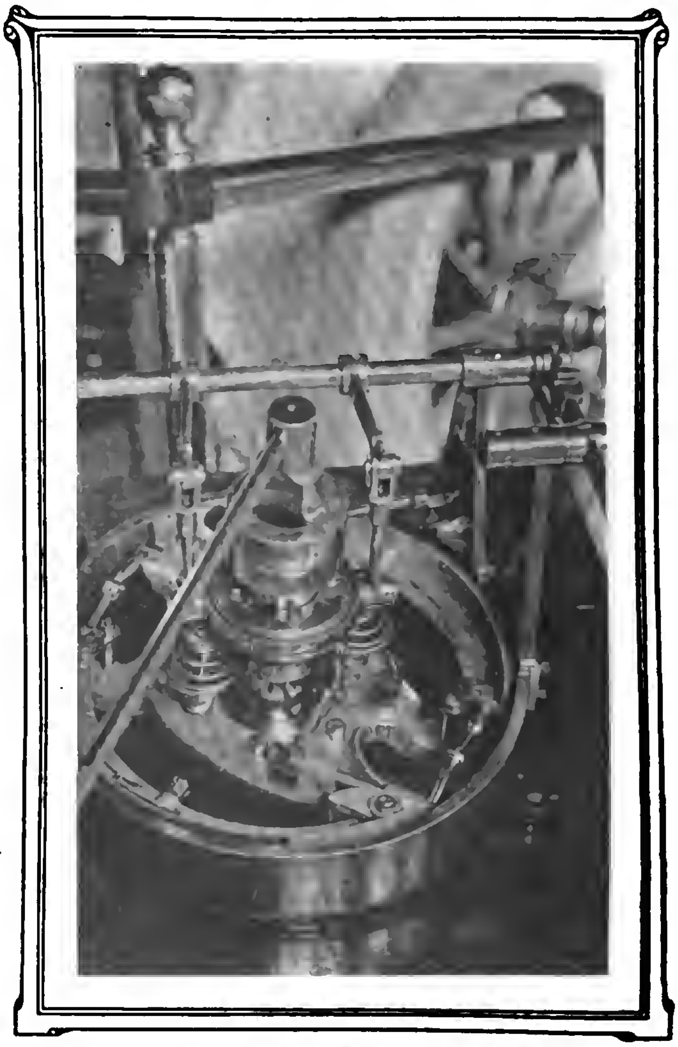
In England, where second-growth hickory or equally good wood for wheels is very much at a premium, wire wheels have reached the highest state of perfection, and are rapidly supplanting wood. This condition is not to be taken as evidence of superiority of wire wheels over wood; it has never been shown that wood, when it is properly selected, and the wheels are suitably made, offers any drawback at all. What the year does indicate, however, is that pneumatic tires were not large enough heretofore, and that in the long run the cost will be very much lower to the autoist if he pays more, provided he secures larger tires in the first place. Larger tires are in evidence in every make of automobile this year, but in purchasing a car it will be the height of wisdom to differentiate as between the cars which are obviously well equipped from the point of view of tires and those which may represent the contrary view.



Locomobile chassis just back of the kick-up of the frame, showing the brake equalizers, spring perch, and U-bolt fastening.

EFFICIENT AND DURABLE BRAKES ARE BEING USED

The most important difference which will be noted in the application this year over last will be found in the location, to a very considerable extent, of the service as well as the emergency brakes upon the traction wheels. There are two schools of design represented in this situation, in one of which it is truthfully claimed that the service brakes will be extremely effective if the drum is applied to the differential shaft, which operates at a higher angular velocity, and since the braking effort is transmitted through the side chain drive, or other mechanism, the inefficiency of this mechanical system helps to stop the car. The braking effort then is maximum for a given applied pressure on the periphery of the brake drum, but, as the other school of design points out, the transmission system must sustain under the work which is induced in the endeavor to stop the car.



Rambler clutch, which is an expanding shoe type within the flywheel, actuated by a double toggle motion.

SELECTIVE SYSTEMS OF TRANSMISSION GEARS DOMINATE

No attempt is ever made to deny the accelerating efficiency of a four-speed transmission system, but motors are now so relatively flexible that the three-speed sliding gear seems to serve every end, excepting, perhaps, in the very large examples of touring cars. That the four-speed system of transmission is limited to the relatively large and high-powered automobiles is proven by its presence in the limited number of cars as follows: Buick Model C, Chadwick "Six," Colburn Model M, Crawford Model G and F-G, Houpt, Keystone 6-60, Kissel Kar Model D-10 and G-10, Locomobile Models 1 and I, Lozier Models H and I, Matheson "Four," Oldsmobile, Palmer-Singer, Peerless Models 27, 28 and 29, Pierce-Arrow Models 36, 48 and 66, Premier 6-60, Rainier, Royal Tourist Model M, Schlosser 24, Simplex 50, Stearns

30-36 and 45-90, Studebaker Model G-7, Thomas Models J and K, White Models G-A and G-B, Winton Models 48 and 60.

Selective transmission gears are now so much used that the progressive systems are only discovered as the result of a diligent search. The best way, perhaps, to indicate the small extent to which progressive systems are employed is to enumerate the cars which have them: Great Smith Model 45, K-R-I-T (two speeds), Middleby, Mora 20, Stevens-Duryea, all models; Autocar, Buffalo (commercial), Gramm-Logan Models X, Y and V (commercial), and Packard (commercial).

ALMOST NO EVIDENCE OF STANDARDIZING PRESENTED

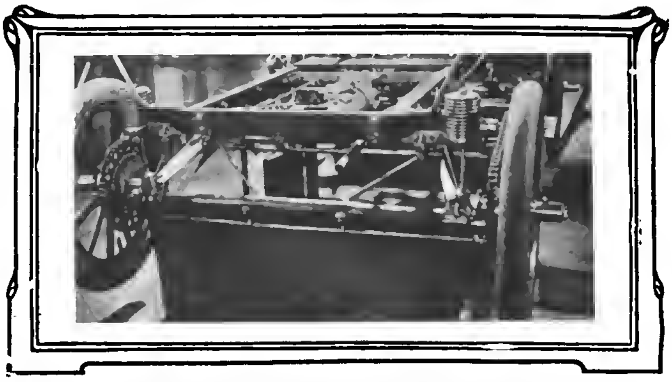
Autoists frequently complain of the varying methods employed in connection with selective sliding-gear systems. Considering three-speed selective systems, it is claimed by many autoists that

Front wheel of the Oldsmobile, showing hexagon hole in the hub and other nice features in design.

they should all be exactly alike, in order that an autoist could take hold of the lever in any car and without the slightest hesitation manipulate the same with absolute confidence, as a matter of habit, and the speed changes should then respond in precise accord with the dictates of his previous experience. Just when this condition will be brought about is difficult to state, but that matters of this sort will ultimately be reduced to a common standard has slight ground for prediction.

BEARINGS USED AND THE LUBRICATING PROBLEM

Plain bearings are now reduced to those which are employed on the crankshafts and connecting rods, insofar as work of great responsibility is concerned, and for the considerable number of bearings in and about the chassis for brake and control levers,



Rear of Brush Runabout, showing the side chain drive, substantial axle, wooden chassis frame and helical springs.

steering gear, spring eyes, and like parts. Beyond this point anti-friction types of bearings are looked upon as desirable, and they are almost exclusively used. When it comes to a classification of these anti-friction types of bearings, however, it seems futile to attempt the task on the ground that in many cars three or four different types of bearings are employed, and, for that matter, there are very few automobiles in which any one type of bearing is used to the exclusion of all others.

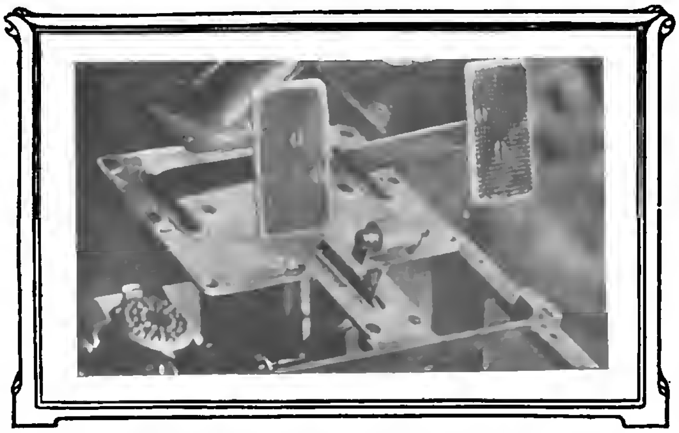
Water cooling obtains in all examples excepting the following: Adams-Farwell, Cameron Models 11, 15 and 16, Franklin Models D, G, H, K-4; Illinois, Kauffman, Kenmore, Metz, Middleby, Ranger Model D.

The block type of motor, which is the most recent idea in cylinder work, will be found on the Acme, Bergdoll "30," Billy Four, Continental "30," Courier, Eastern, Empire "20," Everitt "30," Flanders "20," Ford Model T, Hudson "20," K-R-I-T, Lambert Models 17, 28 and 36, Rider-Lewis, Stearns 15-30, Warren-Detroit, Welch Model R, White Models G-A and G-B, Hudson "20" and Chalmers "30."

POPPET TYPES OF VALVES ON THE WANE

The introduction of the Knight type of motor into the British Daimler in England, Mercedes in Germany, Minerva in Belgium, Panhard in France and Deluca Daimler in Italy, each one of which concerns having experimented for upwards of two years, now report very satisfactory results, and have adopted the Knight motor for the future. In this country four of the big makers have had cars on the road for several months.

Two-cycle work is advancing steadily; the improvements made within the last year were such as to lend encouragement, and the cars which include the two-cycle principle as they were exhibited at Chicago or elsewhere may be set down as follows: American Simplex, Atlas Models F, G and H, Bailey Olympic, Elmore Models 36 and 46 and Paige-Detroit.



Lozier footboard, presenting details of the pedals and method of fastening the steering column.

VARIED FEATURES AND ITEMS OBSERVED AT CHICAGO

CHICAGO, Feb. 5—One hundred and one exhibits of complete cars—that is Chicago's boast. It is the largest number on record for any show ever held in this country. In addition there are close to 200 exhibits of accessories, including 120 members of the Motor and Accessory Manufacturers, and a number of motorcycles. Motor buggies, strange to relate, have almost disappeared. Many new productions of the Middle West are shown for the first time, nearly all of them being of the conventional type, with four or six-cylinder motors, sliding gears and shaft drive. Most of them, too, give a remarkably large amount of "car" for the money, the average being 30 A. L. A. M. horsepower at a price of $1,600.

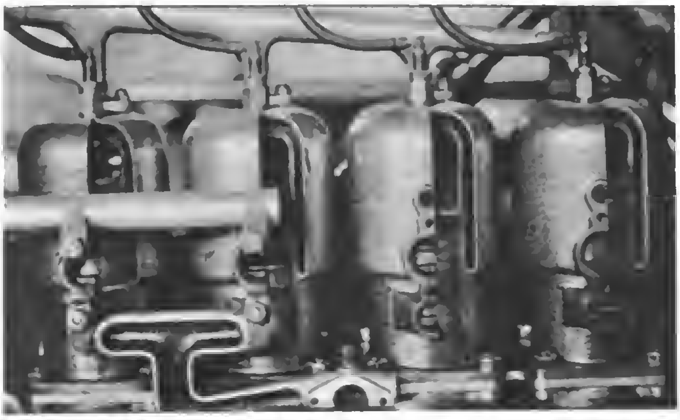


Fig. 1—Elmore four-cylinder, two-cycle motor of the valveless type, with cylinders cut away to show absence of complication.

In its decorative effect the show is exceptionally fine. The Coliseum conveys almost perfectly the illusion of an English garden. Gigantic oaks tower into the blue sky above; beneath, the spaces are divided off by fences of brick and iron, covered with trailing rose vines. In the Annex the scenic effects were limited by a low ceiling, but an impression of spaciousness has been secured by cleaning out the backgrounds between the spaces, and the rose garden decorations give a good effect. The Armory, too, has been enlarged in appearance, and the decorations are attractive and in keeping with those of the other buildings.

As usual, the newspapers, in attempting to spread themselves on show news—for which no one will criticise them—have by the mistaken efforts of cub reporters added considerably to the gayety of the show. One scribe undertook to discuss the Thomas revolving chassis, the same which was shown at New York, on which electrically lighted signs appear to call attention to various mechanical points. His account read as follows: "Tiny lights are distributed through the mechanism of the engine. A touch on a button lights these and the interior of the car then is ready for inspection. A rainy day or a cloudy one is all the same to the mechanicians whose car has broken down far from home. A touch of the button, the break is displayed by the electric light and hours are saved that otherwise would have been consumed in the effort to locate the trouble."

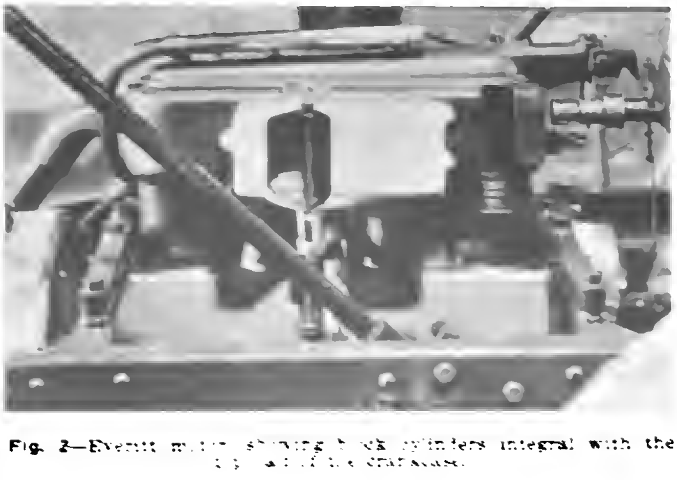

Fig. 2—Everitt motor showing block cylinders integral with the top half of the crankcase.

For almost the first time in history, the opening of the show was attended by good weather. Though the air was a little snappy, still the skies were clear, and the wind was only a zephyr, compared to the blasts of former years. However, Wabash avenue, the stamping ground of the demonstrators, is half blocked with piles of frozen snow from the recent storm.

The Thomas B. Jeffery Company has set into operation a novel idea, in running daily excursions from the show to the new Rambler plant at Kenosha, Wis., for the benefit of prospective buyers and agents. The daily attendance is very considerable.

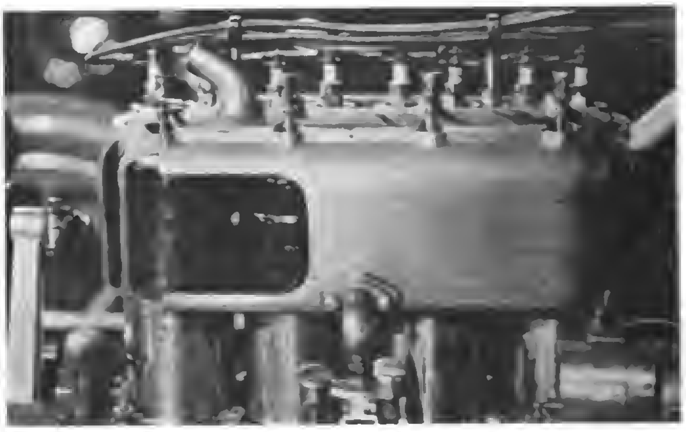

Fig. 3—Hudson Motor of the block construction, with the water jacket cut away and one cylinder sectioned.

Not all the exhibits were ready when the doors were thrown open Saturday afternoon. Premier did not get its cars in till supper time, and on account of its prominent position at the intersection of the two main aisles this was particularly noticeable. Midland was another sufferer from the congestion of railway traffic. At the stand of the Everitt-Metzger-Flanders Company only one car was to be seen, an E-M-F "30." One of the new Flanders "20" runabouts is expected to arrive shortly to round out the exhibit. It is eagerly awaited by the enthusiasts.

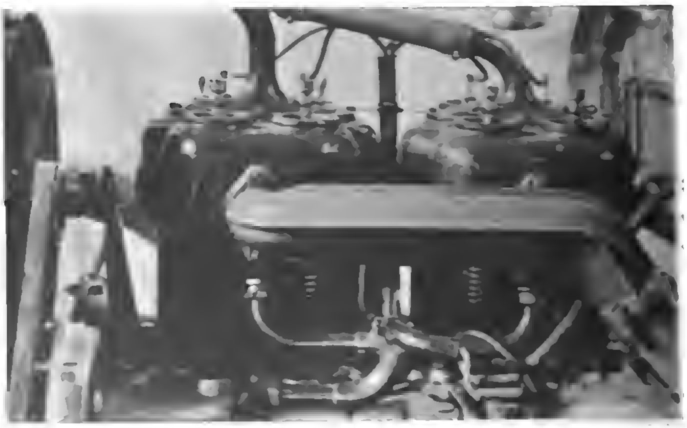

Fig. 4—Four-cylinder Nordyke & Marmon motor, showing large exhaust manifold and capable water connections.

So far as could be seen during the first night, there are only three racing cars in the show. The Alco that won the Vanderbilt Cup, and with it of course the cup itself, appear prominently on the stand of the American Locomotive Company. Thomas has the car that won the New York to Paris race, and Chalmers the "Bluebird" which carried off the Indiana trophy last Spring.

Among the trophies shown, besides the Vanderbilt Cup, are the New York to Paris one on the Thomas stand and the Santa Monica and Portola by the Apperson; Knox, Chadwick, Chalmers and Buick all have extensive collections.

Among the news items which are floating about the show, is one concerning the reorganization of the Grout Brothers Automobile Company into the Grout Automobile Company. The new officers are: Hon. J. W. Wheeler, president; Elisha S. Hall, treasurer; G. E. Dexter, secretary, and Walter J. Gould, sales manager.

One of the newcomers which could not secure space in the big show was Cino, made by Haberer & Company, of Cincinnati. It is shown instead at 1502 Michigan avenue. Four cylinders, 4 3-8 by 5 inches, supply the motive power; the cylinders are cast in pairs with valves in the heads. Constant oil level is maintained

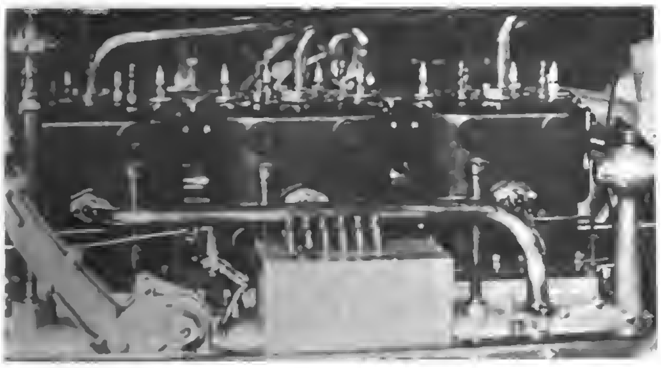

Fig. 5—Stevens-Duryea "Six," with cylinders in pairs, showing the four-feed oiler to the right and timer above cylinders.

by a pump, and a magneto is standard equipment. Multiple disc clutch, three-speed selective gears and a doubly jointed shaft carry the power to a Timken semi-floating rear axle.

Davis is another name hitherto unfamiliar among the ranks of the manufacturers. This standard touring car has four paired cylinders, 4 3-4 by 5 1-4 inches. The wheelbase is 120 inches, and the tires are 36 by 4 both front and rear. The springs are semi-elliptic in front and platform in rear. Multiple disc clutch

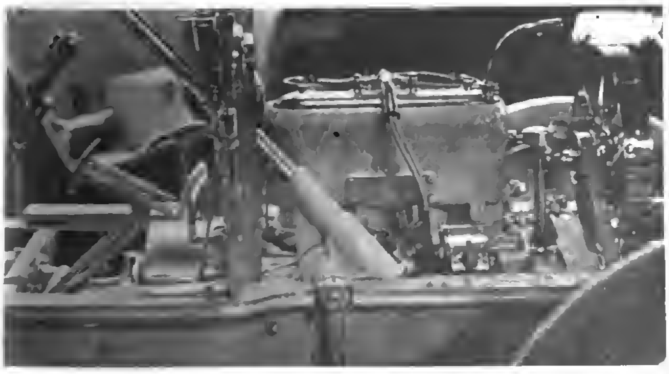

Fig. 6—White motor, showing block castings, long bearing for fan, steering post with shaft passing above chassis frame.

and three-speed selective gear set form the transmitting means; the rear axle is full floating, the shafts running on large imported bearings.

Evidences of quality are shown in the Westcott, among the little details being the milling of integral keys on the gear shaft for the sliding gears, instead of using a square shaft or inserted keys. The motor has 4 1-2-inch square cylinders, cast in pairs with all valves on one side. The multiple disc clutch forms a single unit with the change gear. The wheelbase is 112 inches and the tires 34 by 4.

In the low-price division, the limits of which are now considerably lower than ever before, is the Kenmore, on view at the corner of Michigan avenue and Fourteenth street. This has a two-cylinder horizontal opposed motor, air cooled, rated at 12-14-horsepower. The wheelbase is 82 inches, and either pneumatics or 32-inch solid tires are fitted.

The ranks of the commercial cars have been increased by the advent of the Duntley, made by the Chicago Penumatic Tool Company. This is a light delivery car with a two-cylinder horizontal opposed motor under the driver's seat. The cylinders

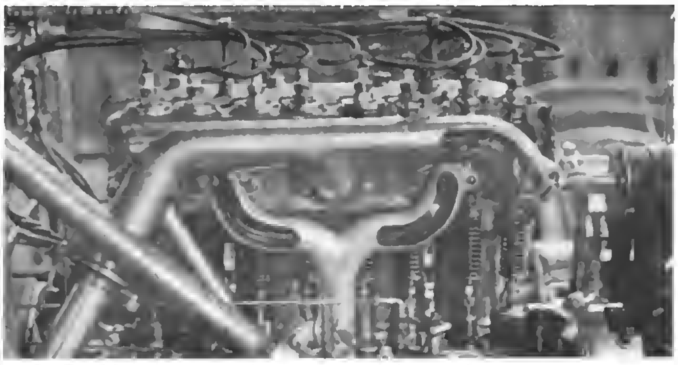

Fig. 7—Hudson block motor sectioned, and manifolds also sectioned to show uniform thickness of walls.

are 5 inches in bore and 4 inches stroke. Cooling is by thermosiphon, ignition by double-unit coil and dry cells, and lubrication by a four-feed mechanical oiler. The gear change is planetary, and drive by side chains in the approved commercial fashion. The wheelbase is 86 inches, and the wheels 36 inches in diameter, shod with 2-inch solid tires.

A foreigner which is almost unknown in this country, outside of Chicago, is the Berliet, imported by Walden W. Shaw. The Berliet design, it will be remembered, was the original of the Alco, although the American car has long since departed from the designs of its French parent, and now it would be a clever man who could trace a resemblance. The Berliet cars range from a 12-horsepower up to a 60-horsepower limousine, and are a fine example of the best French construction.

Torpedo bodies are still quite a novelty in Chicago, and as a result those shown by Knox, Marmon and Winton come in for a good deal of attention. The Knox car with this equipment is a six-cylinder, with a very long, rakish look, due partly no doubt to its wheelbase of 134 inches.

Motorcycles as usual are in considerable prominence, having pre-empted the whole of the second floor of the Coliseum Annex. They do not seem to be quite as strong in numbers as last year, the roll call revealing but twelve makers. Still, they make a gallant showing, and are visited, despite their rather isolated position, by many people to whom their handiness appeals. Many professional men find advantages in their use.

Fig. 8—Mitchell "Six" with cylinders in pairs, exhaust valves in the head, and details of the valve motion.

LATEST NEWS FROM THE CENTERS OF AUTOMOBILE ACTIVITY

FOUR NEW COMPANIES ADDED TO SELDEN PATENT LIST

A. A. A. SOLVES PROBLEMS AT MEETING IN CHICAGO

CHICAGO, Feb. 9—The first session of the Chicago meeting of the A. A. A. was held on Tuesday at the Armory, President Speare in the chair. Those who responded to the call of the roll included Ralph W. Smith, president Colorado State Automobile Association; M. C. Moore, president, and James J. Drought, secretary, Wisconsin State Automobile Association; E. J. Brochannon, of the Kentucky State Automobile Association; Chas. P. Root, president Illinois State Association; John Wilson, of the Pennsylvania Motor Federation; S. M. Butler, of New York, chairman of the Contest Committee; A. G. Batchelder, from New Jersey, chairman Executive Committee; S. A. Miles, general manager N. A. A. M.; Alfred Reeves, general manager A. L. A. M.

The Federal Registration bill came up for discussion, and the consensus of opinion as based upon this discussion was that the bill has an excellent chance of passing during the present session of the Congress, but it was concluded that the chances of success will be much enhanced if the various State automobile associations and the 240 clubs scattered throughout the country will exert a timely effort in the interest of this much-desired legislation.

The best time to select for the presentation of petitions with a view to favorably impressing the Congress will be at the time of the National Legislative Convention of the A. A. A., which will be convened in the City of Washington on February 15 and adjourned February 17. Secretary Elliott's report of the support which this convention is receiving included 33 State associations, and it is contemplated that the National Organization will soon be increased by additions from Florida, Oregon, Tennessee and North Carolina.

Chairman Butler, of the Rules Committee, in his report for 1910 covered the situation most thoroughly, resting it in front of the Board of Directors. Chairman Speare in his address, which was graceful, terse, and comprehensive, stated, among other pertinent matters, that the automobile center is moving westward, and its influence on the good roads situation is being felt, due to the pressure which farmers exert, now that they ride in automobiles. It is the belief of President Speare, that the final solution of the good roads problem lies in the widely disseminated use of automobiles.

During the meeting of the Executive Committee of the A. A. A., which was held in the afternoon at the Armory, this being the regular quarterly session, President Speare made a lengthy address, reviewed the activities of the Association adequately, and among the timely matters acted upon was the passing of a resolution expressing sincere regret over the death of John Farson, who, at the time of his death, was a member of the Chicago Automobile Club, and who will be remembered for his indefatigable activity and wise rules during his occupancy of the presidency of the A. A. A.

Secretary Elliott, in rendering his report, showed that there are 33 States represented in the A. A. A. The revised rules of the Contest Committee, after presentation, were referred to a sub-committee of the Board, which is empowered to act.

After voting to award tokens of esteem and appreciation to H. O. Smith, chairman, Alfred Reeves, the former general manager, and Job E. Hedges, the counsel, arranged for the distribution of a surplus which is in excess of $60,000, which the American Motor Cars Manufacturers Association kept as a balance, the meeting was held at the Southern Hotel yesterday in compliance with the terms of the five-year contract constituting the agreement under which the A. M. C. M. A. was originally banded. The Association was formed in Chicago in 1905, and its unusually successful career could scarcely be terminated without some mention being made of the shows which represented its important annual events. Its membership included 43 companies, all of which were represented yesterday at the gathering. There were speeches of congratulation on the work which was accomplished by the organization, and Chairman Smith was presented with a gold watch, which happy act was duly supplemented by votes for tokens to be presented to General Manager Reeves and Job E. Hedges.

The final resolution which was passed had for its purport the closing of the affairs of the A. M. C. M. A., and it was resolved that the A. M. C. M. A. expressed its high appreciation of the management of the Chicago Automobile Show for 1910, for the completeness of the arrangements and the purity of the artistic display, which was rendered none the less apparent by the interlacing of practical features which had a wide influence for success.

ORGANIZATION OF LICENSED DEALERS

NEW YORK, Feb. 10—At a meeting which is being held to-day, the selling agencies in New York, which confine their operations to licensed automobiles, is busy through its select committee in discussing the details of the organization, formulating by-laws and setting down the preliminaries of the policy which will be pursued by the licensed agents from this time on.

In the meantime, the Selden list has been augmented by the addition of the makers of the Grabowsky, Oakland, Randolph and Reliance, bringing the grand total up to 72 separate makers of automobiles, two of which are foreign makes, namely: Delaunay-Belleville and Lancia. It was stated last week that the licensed association dealers were backed up by the makers of cars under the Selden license, and this prediction seems to have come true. The licensed association is showing evidence of activity in the direction of indicating to purchasers of automobiles that they may expect "squalls" if, in selecting automobiles, they overlook the fact that patent 549,160 has been decided by Judge Hough to cover the basic principle of the automobile.

OVERLAND COMPANY GIVES BANQUET

The Overland Company gave a banquet to its dealers at the LaSalle Hotel on Monday night, which was attended by more than 200 agents from all parts of the country. One of the trophy displays along the row is the showing of the Wheeler & Schebler trophy which is on view in the windows of the Ralph Temple Automobile Company, which handles the Jackson and Fuller. This has occasioned some comment among those who remember the legal war which was threatened following the decision.

GLOOM CAST OVER SHOW CIRCLES

The sad demise of the mother of Manager Miles, which took place in Bristol, England, as the result of shock following a minor operation, was discovered following a cable from England to that effect, and when the executive departments learned of the unfortunate situation they were much affected. The news was not given out, but in some way it became known, and it cast a mantle of gloom over the further activities of his collaborators.

FORD MOTOR COMPANY ACQUIRES PRESSED STEEL PLANT

TO BE INDEPENDENT OF ALL OUTSIDE INFLUENCES

IN CASE OF A GENERAL MIX-UP FORD WILL BE READY

DETROIT, Feb. 9—When the A. M. C. M. A. is disbanded, as it certainly will be within the next few days, the Ford Motor Company will be alone in its fight against the owners of the Selden patent, and according to the Ford attitude, there is little to be feared from Selden interests by way of a direct Court attack. The Ford idea is to look out for flank movements. If the Selden interests should cut off his source of supply, Ford would have to come to terms, and in order that this condition may not be brought about, the Ford Company is closing in on its source of supplies. That is to say, Ford is making complete and thorough provision for all contingencies.

The John R. Keim mill, which is located at Buffalo, and employs about 600 men, has fallen into the control of the Ford Company by the purchase of the Spaulding interest (for Ford account) in this plant. The Keim plant is especially well fitted out to make such pressed steel products as are necessary in the production of Ford cars. It will be remembered that the Ford design is one which utilizes pressed steel to a marked extent, and the acquisition of this well-equipped plant by the Ford Company represents a move of the greatest importance. The John R. Keim mills is incorporated and has a capital stock of $350,000.

OFFICIAL AUTOMOBILE BLUE BOOK WORK

CHICAGO, Feb. 10—The Automobile Blue Book Publishing Company, who are hard at work on their 1910 editions, report very satisfactory progress in all branches of their work. During the driving season of 1909 they had three, and frequently four, crews of two men each covering the roads embraced in the several sections they publish.

Messrs. Robert Bruce and John F. Mixer traveling in New Jersey, New York, Pennsylvania, Delaware, Maryland, the District of Columbia and Canada, revised several thousand miles of old routes and added approximately 10,000 miles of new route matter—Canada, west of Montreal having about 2,500 miles.

Messrs. E. R. Mixer and Henry MacNair devoted their time and energies to the New England States and Canada east of Montreal, revising many of the old and connecting them with new routes and compiling text for about 11,000 miles never before routed. Covering Maine as thoroughly as Massachusetts, something heretofore not done.

Messrs. John P. Dods and Fred E. Lee have spent their time in the Western territory adding many connecting routes in Ohio, Indiana, Michigan, Illinois, Wisconsin and Iowa, and have invaded Minnesota, Nebraska, Kansas, Missouri and Kentucky. They have run three routes to St. Paul and Minneapolis from Illinois and Iowa points, two trunk lines across Iowa with many connecting links. A new route from Sioux City, via Omaha, Lincoln and Kansas points, to Kansas City, and a route from the latter city to St. Louis—a route never before published—securing about 10,000 miles of additional mileage.

Messrs. N. H. Van Sicklen, Sr., president of the company, and E. R. Mixer made the New York-Atlanta-Savanah and return trip, which will, with other matter since secured, give a direct route from all northeastern points to the South as far as Jacksonville, Fla., adding over 3,000 miles of new matter in a territory heretofore practically unknown to tourists.

A new style text, more easily followed, has been adopted, new and more explicit maps are being prepared and an entirely new system of indexing will be used, rendering the information contained in the various routes more easily located.

All sections will be ready for delivery April 15, and will undoubtedly surpass anything heretofore attempted in automobile road book and route work.

FEBRUARY MEETING A. S. M. E.

The American Society of Mechanical Engineers will hold its monthly meeting on February 8, in the Engineering Societies' Building, West Thirty-ninth street, New York City. This meeting will be devoted to the dedication of the memorial tablet to Dr. Robert H. Thurston, first president of the body.

CHICAGO AUTO TRADE ASS'N BANQUET

CHICAGO, Feb. 5—The fourth annual banquet of the Chicago Automobile Trade Association was held last night at the Chicago Athletic Association, there being 150 of the local dealers and their friends in attendance at the dinner, Thomas J. Hay, president of the association, acting as toastmaster. It was the most successful affair ever promoted by the dealers, and the speechmaking was most interesting. Prominent in the talkfest was Father M. J. Dorney, a priest from back of the yards, who delivered a running fire of witticisms on motoring in general, declaring that although he used to be an ardent admirer of horses, he had been converted, and that now he would not give up his motor car for a seat in kingdom come. Walter J. Moody, manager of the Chicago Association of Commerce, spoke on co-operation, and told of the mighty deeds that were possible if the dealers would only work as a unit in striving to promote the interest of the association. Howard W. Hayes, assistant corporation counsel, was much wrought up over the fact that the Illinois state motor law took away from the city the right to set a speed limit, but is somewhat reconciled because of the passage of an ordinance which makes it compulsory the examination of chauffeurs on public-hire vehicles. Mr. Hayes hung out a ray of hope to Chicago motorists who have been fighting against the wheel tax, declaring that the license committee of the city council was even now considering a reduction of the tax with a view to taxing by horsepower rather than seating capacity. Ira M. Cobe, president of the Chicago Automobile Club, intimated that the Cobe cup race this year will be run on a speedway, which is to be built within 40 minutes of Chicago. At the same time he gave an inside light on the loss sustained on the Crown Point carnival last summer, declaring that the club went $1,500 into the hole, largely because of the construction of fifty-four private grandstands around the course, thus depriving the club of revenue which was its due. Samuel A. Miles made a clever speech on shows, while David Beecroft, president of the Chicago Motor Club, wound up with a dissertation on the American Automobile Association, in which he urged the Illinois motorists to rouse themselves from their lethargy and assist the national body in the control of motoring sport.

LICENSED RANKS BULGING WITH MEMBERS

The latest announcement of the A.L.A.M. is to the effect that the membership is now 72, which includes two foreign makes of automobiles, i. e., Delaunay-Belleville and Lancia. The dealers who handle licensed automobiles are making a campaign in the interest of licensed interests, and, from all accounts, they are in close touch with the situation from the licensed point of view.

Small Cars Prominent on the Stand of the Belgian F. N.

BRUSSELS SCENE OF

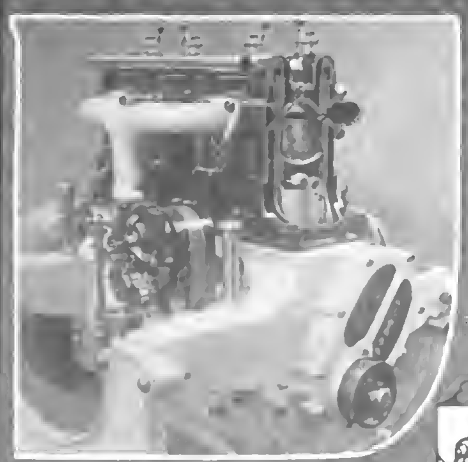
BRUSSELS, Jan. 30—Automobile expositions are rare in Continental Europe, and the one which closed this week in the Belgian capital therefore had all the more success. This, the ninth annual event, was held, like its predecessors, in the Palais du Cinquantenaire, a large hall well suited for the purpose, and tastefully and uniformly decorated for the reception of the automobiles. Although all the leading European firms are present, the show is not distinguished by the appearance of any new models, as in the absence of the Paris salon the makers did not think it worth their while to get these out.

The American exhibits comprise Mitchell, with a full line shown by the recently appointed Paris agent, René Petard, and Ford, which has been on the European market for a considerable time. There are also several American exhibits of tires and accessories.

Aeronautics are an important section. The dominant feature of the hall is the dirigible balloon "Belgica," built in France, but fitted with a Pipe (Belgian) motor of 160 horsepower. This is partially inflated and suspended from the roof. The car beneath it can be reached by the spectators from stairways on each side, and this opportunity to inspect at close range the fittings of a large dirigible is not neglected. Practically all the well-known aeroplane firms are exhibiting, among them being Antoinette, Santos-Dumont, Blériot, Voisin, Farman, Hanriot and a number of lesser Belgian constructors. Hanriot, though a comparative newcomer in this line, shows a monoplane of neat design, with skids for landing in addition to two wheels for starting.

Minerva, a native Belgian, is attracting much attention with its exhibit of motors using the Knight slide valve. The 1910 line of this company uses this valve system exclusively, the motors being built in 16, 26 and 38-horsepower sizes, all four-cylinder. The exhibit includes a motor completely sectioned to show the working of the two sliding sleeves inside each cylinder. The camshaft which operates the sleeves is chain-driven.

On the Pipe stand interest centers about a large car with what may, in the lack of a more appropriate term, be designated as a limousine body; the outfit was specially designed for the crossing of the Sahara Desert. The car has a six-cylinder motor of 105 and 125 millimeters bore and stroke (approximately 4 1-8 by 5 inches). The rear wheels are fitted with twin pneumatic



Minerva Motor with Knight Slide Valves

Rochet-Schneider Idea of a Torpedo Body, with Left-hand Control

Complete Exhibit of Daimler, the Prominent English Firm

tires, like those used on light commercial cars. The body, however, is the real feature. The front part has two transverse open seats, like a wagonette; behind this is the closed part, which can be adapted for sleeping purposes. The rear end of the closed part is made in one solid piece, which can be let down flat on the ground to form a floor. A folding table, camp stools and an awning can all be stowed away in the body; when they are brought out and suitably disposed on the floor, the mid-Saharan desert will be transformed into a lunch-room.

Vivinus having had some success in the building of aeronautic motors is striving for more. It will be remembered that Roger Sommer once used an ordinary automobile-type Vivinus motor on his Farman biplane, and established a duration record with it. Now Vivinus has brought out a motor specially designed for aeroplane use, a four-cylinder said to develop 70 horsepower, and weighing 140 kilograms (about 300 pounds). The motor is very simple and clean in appearance; the cylinders are paired and fitted with copper water jackets, and all valves are in the heads side by side.

Among the other Belgian firms exhibiting are the Fabrique National d'Armes de Guerre, usually abbreviated to F. N., and Germain. The F. N. company concentrates on small cars, and its productions are well known in Europe, although they have never penetrated to America. Germain shows a block motor with overhead valve action, which, even for this type, is surprising in its simplicity. Not a working part is visible except the flywheel and the front extremity of the crankshaft.

The French firm of Rochet-Schneider has a fine example of the torpedo type of body, which is just penetrating to the Continent from its natural habitat, England. This car has the driver's seat on the left, with the levers in the center; this is a very convenient method of dodging the usual issue in torpedo bodies, namely, whether the levers are to be inside or outside of the body wall. Daimler, the first firm to adopt the Knight slide valve, has a good exhibit. All of its cars are fitted with detachable wire wheels. The worm-driven models are quite prominent. Some very neat body work, although not of the torpedo type, distinguished this English exhibit.

The Belgian constructors are jubilant over the success of their show. The obstinacy of the French manufacturers in refusing to back the Paris salon has resulted in a great boom for the industry in the sister country.

AUTOMOBILE TRADE CREDIT MEN MEET

THE fourth annual meeting and dinner of the Automobile Trade Credit Association was held at Hotel Astor, New York, on January 19. This association is a very broad one, and its influence upon the trade at large is far greater than would be suspected. Believing that there is strength in union, this meeting is held each year for organization and a review of the situation.

The following were represented:

Lovell-McConnell Mfg. Co., by Messrs. Lovell, Turner & McConnell.
C. Cowles & Co., by L. C. Cowles.
Hartford Suspension Co., by Messrs. Waterman, Montgomery and Burnett.
N. Y. & N. J. Lubricant Co., by Mr. Barnes.
Continental Caoutchouc Co., by Mr. Lemal.
American Thermo-Ware Co., by Mr. Marshutz.
Motor Car Equipment Co., by Messrs. Kaufman & Lowe.
Nonpareil Horn Mfg. Co., by Messrs. Cohn & Arlitz.
Royal Equipment Co., by E. B. Knowles.
Nathan Novelty Mfg. Co., by Edwin B. Nathan.
Westchester Appliance Co., by Henry M. Duncan.
Ajax Trunk & Sample Case Co., Messrs. Kallis and Berg.
Patterson, Gottfried & Hunter, Ltd., by Charles H. Kreuger.
Mutual Auto Accessories Co., by Messrs. Phelps and Nesbit.
N. Y. Sporting Goods Co., by C. T. Hutcheson, J. B. Koebler.
Class Journal Co., by E. M. Corey.
Automobile Topics, by E. E. Schwartzkopf.
Motor World, by Jos. Goodman.
C. F. Splitdorf, by Messrs. W. J. Murray, Murphy and Schindler.

During the past year the following firms were elected to membership:

Aluminum Foundry Co.,	Manitowoc, Wis.
Ball-Fintze Co.,	Newark, O.
Grossman Co., Emil,	New York City.
Hoyt Electrical Instrument Works,	Penacook, N. H.
Havoline Oil Co.,	New York City.
Hagstrom Bros. Mfg. Co.,	Lindsborg, Kan.
Hazen-Brown Co.,	Brockton, Mass.
Jeffery-Dewitt Co.,	Newark, N. J.
Lovell-McConnell Mfg. Co.,	Newark, N. J.
Mutual Auto Accessories Co. of America,	New York City.
Motor Field,	Denver, Colo.
Nonpareil Horn Mfg. Co.,	Brooklyn, N. Y.
Reading Steel Casting Co.,	New York City.
The Rutherford Rubber Co.,	Rutherford, N. J.
Swan & Finch Co.,	New York City.
Standard Automobile Supply Co.,	Chicago, Ill.
Sonneborn Sons, Inc., L.,	New York City.
Union Battery Co.,	Belleville, N. J.
Westchester Appliance Co.,	New York City.
Wright Cooler & Hood Mfg. Co.,	Chicago, Ill.

Messrs. Carl Kaufman (Motor Car Equipment Co.), Michael J. Martin (Geo. A. Haws) and J. J. Cohn (Nonpareil Horn Mfg. Co.) were elected to fill vacancies on the Board of Directors.

Acting President Carl Kaufman was in the Chair during the business session, and Charles H. Krueger, of Patterson, Gottfried & Hunter, acted as toastmaster during the dinner, which was much enjoyed by all in attendance, as well as the guests.

THE AUTOMOBILE CALENDAR

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.
Feb. 8-14.........Los Angeles, Cal., Grand Avenue Rink, Automobile Dealers of Southern California, Automobile Show.
Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main street.
Feb. 14-19........Hartford, Conn., Foot Guard Armory, Third Annual Show, Hartford Automobile Dealers' Association.
Feb. 14-19........St. Louis, First Regiment Armory, Fourth Annual Automobile Show, St. Louis Automobile Manufacturers' and Dealers' Association, Robert E. Lee, Manager, 1629 Washington avenue.
Feb. 14-19........Rochester, N. Y., Convention Hall. Third Annual Show, Rochester Automobile Dealers' Association. Captain C. A. Simmons, Manager.
Feb. 15-19........Washington, D. C., American Automobile Association's National Legislative Convention.
Feb. 17-19........Grand Rapids, Mich., First Annual Automobile Show, Grand Rapids Automobile Club.
Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.
Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.
Feb. 19-26........Los Angeles, Cal., Hamburger Building, First Annual Show, Licensed Dealers of Los Angeles.
Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South street.
Feb. 19-26........Cleveland, Central Armory, Annual Automobile Show under auspices of the Cleveland Automobile Show Company. H. M. Adams, Secretary.
Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.
Feb. 22-26........Baltimore, Second Annual Automobile Show, Auto Club of Maryland, Fifth Regiment Armory.
Feb. 21-26........Portland, Me., Auditorium, Fifth Annual Automobile Show. F. M. Prescott, Manager.
Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.
Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.
Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Mgr.
Feb. 28-Mar. 5....Omaha, Neb., Auditorium, Automobile Show, Omaha and Council Bluffs Automobile Dealers.
Feb. 28-Mar. 5....Kansas City, Convention Hall, Fourth Annual Automobile Show, Kansas City Automobile Dealers' Association.
Mar. 5-12.........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park square.
Mar. 5-12.........Des Moines, Ia., Coliseum, First Annual Automobile Show, Des Moines Automobile Dealers' Association.
Mar. 7-12.........Albany, N. Y., Armory, Automobile Show.
Mar. 12-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.
Mar. 17-19........Louisville, Ky., Armory, Louisville Automobile Dealers' Association Annual Automobile Show.
Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsman's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.
Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.
Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.
Mar. 26-Apr. 2....Montreal, Coliseum, Motor and Sportsmen's Show. E. M. Wilcox, Manager.
Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

WHAT ARE DANGERS OF IMMEDIATE FUTURE?

It is claimed by some that the growth of the automobile business is at a rate so rapid that it will act as a sponge and draw wealth from other industries so appreciably that they will suffer, and, in the course of time the reaction which will set in will be to the detriment of the automobile industry.

This claim, if it has any foundation at all, is not working out in the fullest accord with its sponsors. The machine-tool industry would have gone to the wall just after the panic were it not for the demands which the automobile business made on the machine-tool manufacturers; a demand which has been so heavy and persistent that it has pre-empted nearly all the time of every machine-tool maker who was capable of doing even reasonably fair work.

There is no reason why an industry, even if it does grow and prosper, should damage any other branch of trade or manufacture; if some other industry is in the throes of overproduction, as the machine-tool situation seemed to have been, business from some newer source will always be the medicine which will cure the malady.

The real way to get at the facts in a matter of this sort, is no different from the method which must be pursued in an attempt to ascertain as to the food value of potatoes, or the fuel value of coal. Energy is what must be kept track of in every case. Food is measured, in determining its value, by ascertaining its heat units (the energy contained in a pound of the food). Fuel is counted in the same way, and, when the force of an industry is properly gauged, it will be found that accuracy will creep in if the energy engaged is counted.

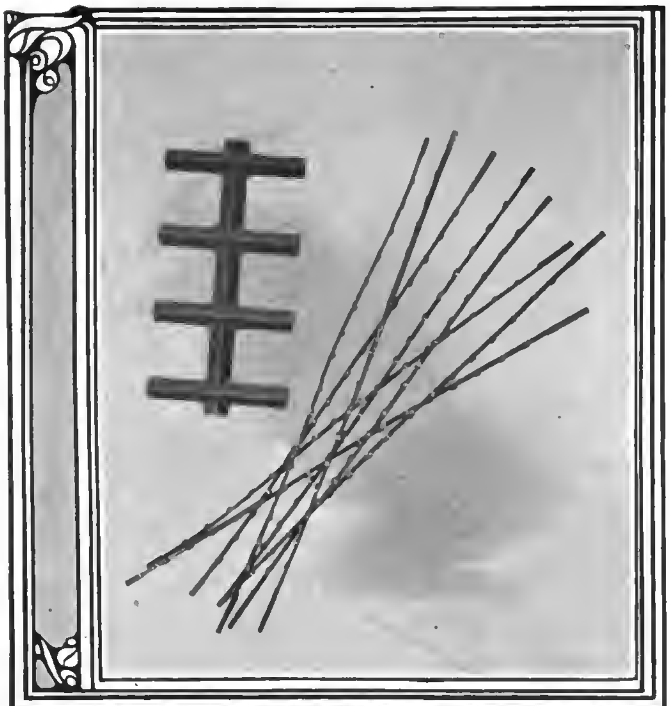
Fuel, if it takes on the characteristics of dynamite, is so concentrated that it must be handled with care, and food, when it is too rich, is likely to result in indigestion. In the same way, if an industry is over energized, it will become congested. This was the condition of the machine-tool industry—showing an excess of energy, and, when the automobile situation hove in sight, in want of energy, it tapped the excess of the other, resulting in good to both.

Over production, then (excess of energy), is the condition which must be watched, and, that the automobile industry is on this basis is not believed. The time may come when the fathers of the industry will see the need of applying the brakes; that they have a set, is well understood by all who have skill enough to appreciate the status of the industry.

The second-hand car situation is a little threatening; some phases of it must be treated with, and it is a question of some portent; a matter which may have to be mastered by the makers before the end of the chapter. Perhaps, as once before suggested, makers will find a way to control the repair and further exploitation of second-hand cars, and, if they are in a state of decay beyond repair, it may be desirable to fund a holding company which will sustain the loss.

In the rush to deliver a larger number of automobiles than last year, it may be that some of the relatively unimportant details will be given less attention than they should receive; this will be a great detriment to the industry; each person wants but one automobile; he is entitled to a good one; the price demanded should suffice for the purpose, but there should be no question as to the quality of the automobile any more than there should be a question as to the soundness of the currency demanded.

Materials, when they are required to do kinetic work, must be especially fabricated for the purpose, and if this important matter is overlooked, it is a corps of failures that will greet the eye of the historian. It is to be hoped that history will not be of the kind which will tell of failures of this character, nor is it to be expected that the makers who have gone through this phase of the undertaking will be so short of vision as to play the part of the penny wise. Progress has been made in this direction, but it is difficult to get steel men to realize the necessity of doing their best, and unfortunately, it takes months, even years, to bring a series of experiments to a point where the deduction may be relied upon.



NEW EDISON BATTERY

SIX years ago Thomas A. Edison announced that he had succeeded in solving what was then termed "The storage battery problem." The first battery which Mr. Edison placed upon the market was known as Type E, and it differed from the then prevailing types of storage batteries. The Edison battery belonged to the alkaline electrolyte series, whereas the prevailing types of batteries at that time were of the lead-lead series, in which the active material was peroxide of lead and the electrolyte was diluted sulphuric acid. There were other types of batteries, but they failed to impress commercial users for divers reasons which will not be explained at this time.

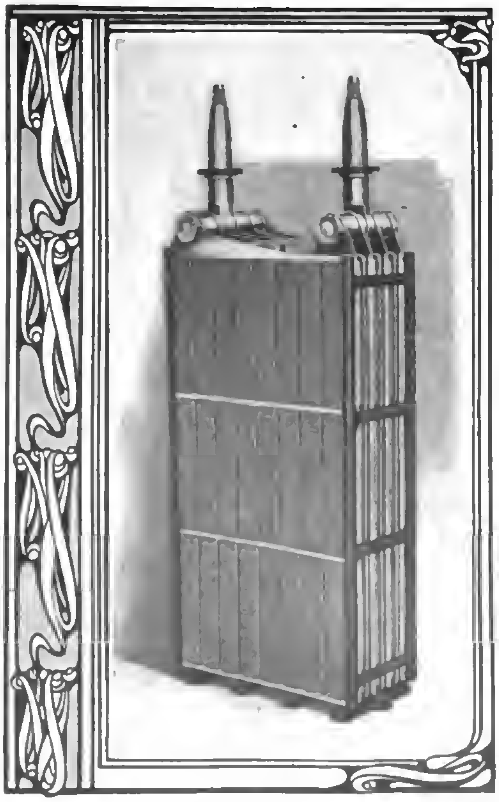


Fig. 1—Showing positive and negative plates of the A-4 Cell assembled together, but removed from the container.

The type E Edison battery, while it may not have accomplished as much by way of an invasion of the market as the public might have expected, did survive, and the electric vehicle problem was given an extra impetus as a direct result of its use.

That Mr. Edison was not as well satisfied with the Type E battery as the users thereof, is proven by the fact that the Edison Storage Battery Company of Orange, N. J., is now offering what is known as the new Edison battery, and is commercially catalogued as Type A. A cell of this battery is composed of four positive plates, when it is called Type A-4; likewise, if the plates are increased to six it is then called a Type A-6 battery.

Fig. 2—Type A-4 Cell with contents of container partly lifted, showing alternating positive and negative plates assembled and connected with positive and negative poles, respectively.

The alkaline electrolyte is used in this battery just as it was in the first battery produced by the Edison Company, and the difference lies in structural refinements, a better understanding of the electrochemical phenomena, and data which has been turned to good account. In battery construction, as in other lines of work, experience is the best teacher.

In the new Edison battery the active materials are oxides of nickel and of iron. The nickel oxide is placed in the positive grids and the iron oxide is lodged in the negative electrodes. The electrolyte is a solution of caustic potash in water.

The retaining cans are made of sheet steel. In the process of manufacture, the sheets are rolled into the required shape, and the seams are made permanent and tight by the autogenous welding method. To limit weight as much as possible, the sheets of steel are selected with the idea of having to corrugate them in order to induce the required measure of strength. The cans, when so made, are electroplated with nickel, and the desired close union of the steel and nickel is obtained by fusing them together. This coating of nickel is primarily given to prevent rusting, but it is also recognized that it adds materially to the general appearance of the cans.

Since the only diperence between the Type A-4 and the Type A-6 cells is due to a difference in the number of plates used, any further description may well be confined to the Type A-4 cell, and its combinations. As before stated, the Type A-4 cell is made up with four positive plates, and since it is desirable to have a negative plate on each side of each positive plate, five negative plates are employed.

Each positive plate consists of a grid of nickelplated steel, binding into intimate relation 30 tubes, each one of which is filled with active material. These tubes are arranged in two rows of 15 each.

The tubes are made of sheet steel, relatively thin, after the sheets are perforated, and when the tubes are completed they are then nickelplated. Eight stout ferrules are placed over each tube, the object being to so reinforce and strengthen the tubes that they will resist expansion which takes place when the battery is in active service.

The tubes are filled with a combination of active material and thin layers of pure metallic nickel in the form of leaves or flakes. The pure nickel flake is a product which is especially manufactured for the purpose by an electro-chemical process which was instituted in the Edison plant.

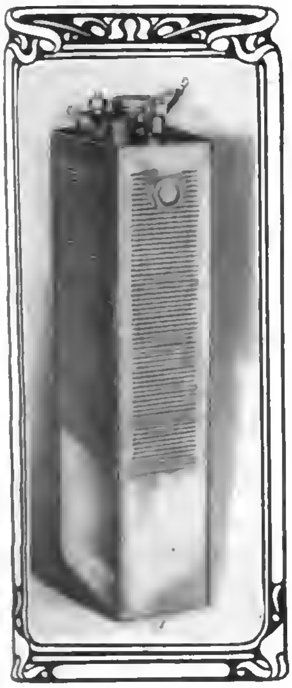

Fig. 3—Cell complete ready to go into a battery of cells.

Each negative plate comprises 24 flat rectangular pockets, supported in three horizontal rows in a nickel plated steel grid. These pockets are made of thin nickel plated steel, perforated with fine holes. The pockets are filled with oxide of iron.

The positive and negative plates are assembled alternately as shown in Fig. 2, and, as will be observed, all the positive plates are connected together by means of one cross bar, and all the negative plates are connected together in the same way by a second cross bar. The plates are exactly spaced by means of spacers which are made of tubing, and which measure the distance between the respective plates, being held in proper relation by the bolts, which serve as the connecters.

Each cell of battery, according to this description, is composed of an even number of positive plates, which are flanked by an odd number of negative plates. The outer surfaces of the outer negative plates are insulated from the retaining can by means of hard-rubber sheets. As a further means of insulation, hard-rubber pieces are fixed between the cans and the sides and bottom edges of the plates. Additional protection is maintained through the use of hard-rubber rods inserted between the plates. When the elements are placed in the cans, the covers are put on and tightness is secured by autogenously welding the covers to the cans.

The covers are designed in such a way that the columns of the positive and negative plate connecters pass through stuffing box apertures, these boxes being a snug fit in order that the electrolyte will not slop out, and are shown in the cover, which is placed beside the can in Fig. 6. In order that the electrolyte may be replenished from time to time as the exigencies of service will demand, a filler opening is provided, and a cover maintains tightness of the filler, excepting when it is removed for the purpose of adding distilled water to take the place of that which is evaporated during the time when the battery is in operation or undergoing the process of charge. There are many nice refinements in connection with the design, as, for illustration, the water cap is so made that it will fly open unless the catch is properly adjusted, the idea being to indicate to the operator when the caps are properly secured.

The strength of the electrolyte is that which will follow when 21 per cent. solution of caustic potash is dissolved in distilled water.

CAPACITY OF TYPE A-6 EDISON BATTERY

Charged Seven Hours at 45 Amperes. Discharged at 45 Amperes.

Ampere-hour input	315.0
Ampere-hour output	268.5
Average potential difference of charge	1.692
Average potential difference of discharge	1.202
Watt-hour input	533.0
Watt-hour output	322.7
Ampere-hour efficiency (per cent.)	85.2
Volt efficiency (per cent.)	71.1
Watt-hour efficiency	60.6
Output per pound in watt-hours	16.8

The curve falls quite rapidly from 1.50 to 1.30 volts within 30 ampere-hours discharge, falls from this level to 1.20 between 30 and 150 ampere-hours discharge, and falls to 1.11 between 150 and 240 ampere-hours discharge. From this point on, the voltage falls with great rapidity, reaching as low as 1 volt per cell between the discharge 240 and about 268 ampere-hours. These values are approximate, and would necessarily vary over a considerable range under different conditions.

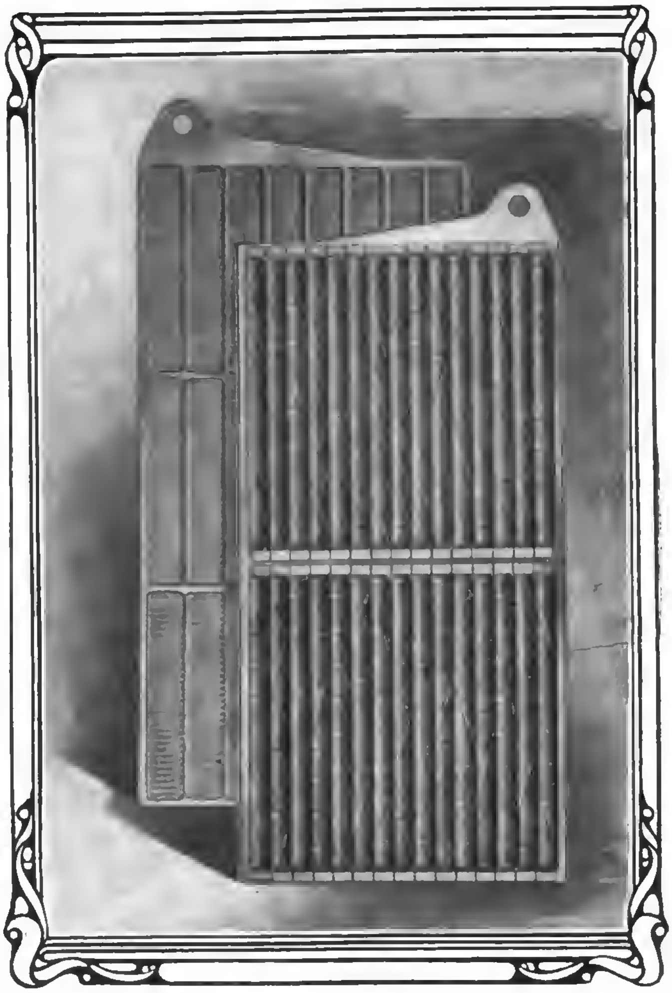

Fig. 4—Type A, positive and negative plates, showing the different structures of each, one tubular and one rectangular.

On charge the voltage goes up from 1.45 approximately to 1.64 at a steep rate, say, before the input reaches 40 ampere-hours. The charging voltage remains at about 1.67 until the charge reaches a little more than 180 ampere-hours. Beyond this point in the charge the voltage increases and reaches 1.80 when the input is equal to about 285 ampere-hours. The watt-hour output is equally high.

Fig. 5—Type A-4 Cell, showing the positive and negative plates in the container, and also showing the removed cover with openings.

IN THE GARAGE REPAIR SHOP

OVERHAULING an automobile seems a simple undertaking, if machinists of some skill are employed in the process. It would be perfectly simple were all automobiles so made that the parts would be interchangeable in fact. This condition, while it is said to obtain in every car made, is, nevertheless, so very difficult to realize that it is doubtful if it positively exists in even a reasonable percentage of automobiles.

This question of interchangeability has two important phases. They may be separated from each other as follows:

(A) Connecting members of ordinary importance may be so nearly interchangeable that a little "shake" makes no great difference, unless its magnitude is sufficient to induce noise.

(B) Relating members of ordinary importance may be so near a proper fit that a little "lapping" will suffice to make them go together.

(C) Certain members, as ball bearings, may require a "sucking" fit, and this precise condition may demand that the very bearing which is removed from a given spindle will have to be put back on the same spindle.

Considering the specific conditions as above enumerated, it follows that an artisan may be skilled in some of his divers ways, but he may not have the acumen which will be necessary if the parts, as ball bearings, have to be marked, kept track of, and at the proper time be put back on the exact spindle from which they may have been taken. The first point of importance, when it comes to repairing an automobile, according to this method of reasoning, will be suitably cared for if the parts are "spotted" as they are removed, so that they may be identified with the position which they are supposed to occupy when the car is reassembled.

Unless some well understood system of spotting is contrived, it will be necessary for the man who may have made the identifying marks to do all the work of reassembling, for the reason that no other workman would be in a position to determine as to where the parts belonged. This condition means additional work, with much cost added also. The cost of assembling under such conditions would necessarily be high, but unfortunately what really does happen in nine cases out of ten is that the identifying marks are totally disregarded if in the assembling process the parts will go together, which, however, is excellent assurance of the fact that the car will not be assembled in a manner which will favorably compare with its condition when it left the works of the maker.

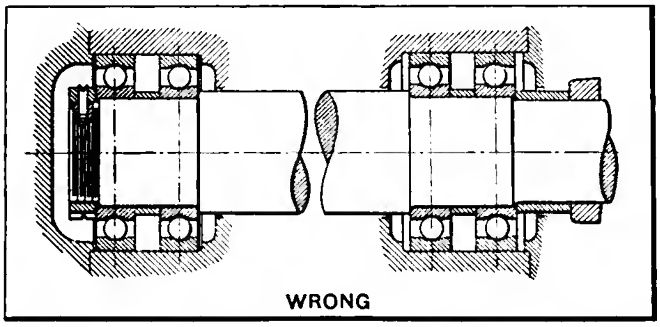

Fig. 1—Wrong nesting of ball bearings which support the two ends of a long shaft.

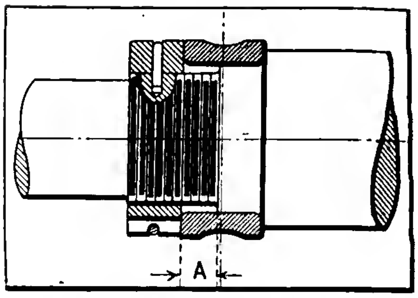

Fig. 2—Method of clamping inner raceway of an annular type ball bearing, showing threaded ring and locking device.

In some of the relatively old models of automobiles, the annular types of ball bearings were not fitted into place in full accord with present standards, and it is just these cars which are now likely to visit the repair shop. The earlier practice was to fit the inner raceway to its bearing on the spindle so tightly that by virtue of the pressure generated it would stay in place—a press fit. This character of fit served every end when the material of the spindle was of some excellent grade of alloy steel, properly heat-treated. In many cases, however, the steel was of a softer variety and the press fit failed to serve the end, so that the inner raceway of the bearing so fitted loosened up on the shaft and burrowed into it.

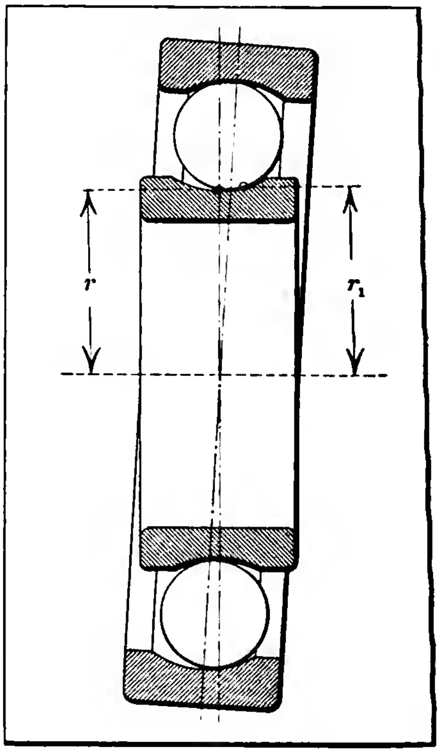

Fig. 3—Showing position which is assumed by a ball bearing if the outer raceway is pushed over to one side.

When this difficulty reached sufficient prominence to warrant giving it specific attention, the problem was taken up by Henry Hess of the Hess-Bright Ball Bearing Company, and this company thereafter issued specific instructions to the effect that the inner raceway should be a sucking fit on the shaft, and it should fetch up against the shoulder, using a threaded ring or other suitable nut for the purpose, and the nut in turn should be locked after it is screwed up tight. Fig. 2 shows just how this fit is made with the threaded ring and the wire lock. In this particular example, it would seem as if the distance (A) is excessive, but it accentuates another point very thoroughly, i. e., the thread should be cut back for a sufficient distance under the inner raceway so that the locking ring may be screwed up without interference, which latter condition is frequently present when the design is cramped, and a condition of give and take is not allowed for.

In making a repair, if account is taken of the conditions as above enumerated, the repair man will necessarily make an effort to have the inner raceway fit snug on the shaft in every case, and, when possible, employ some locking rings for the purpose of clamping the inner raceway so that it will not float on the shaft, and so tightly that it will not rotate, excepting with the shaft. It

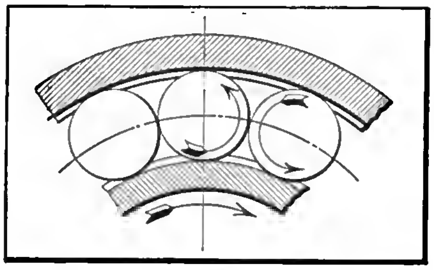

Fig. 4—Portion of an annular type ball bearing, showing directions of rotation of inner race and balls.

may be a little difficult in some of the older designs of automobiles to bring about this desirable condition, but it is well worth striving for, and it is the repair man who takes these nice details into account who will deliver the greatest measure of satisfaction, and number among his customers those who are willing to pay liberally if the results obtained are in keeping with the promises which have been made.

Annular types of ball bearings are capable of taking thrust as well as radial loads, but unless the thrust load is to be taken, it is important that the outer raceway be given a certain axlewise freedom, and the fit of the outer raceway in the bore of the housing should be barely "snug." If the bearing fetches up against the shoulder which will crowd the outer raceway when the inner raceway is clamped into its right position, the bearing will be crowded over as shown in Fig. 3 during a part of its rotation, which condition will be brought about by deflection of the housing or the spindle. If it is not crowded over diagonally as shown, it will at least be displaced so that the balls will press against the curvature of the races instead of rolling in the normal position as shown in Fig. 5. That the bearing will last as long under such conditions is scarcely to be expected, and that it will fail in service is assured, unless it is much too large from the point of view of normal service.

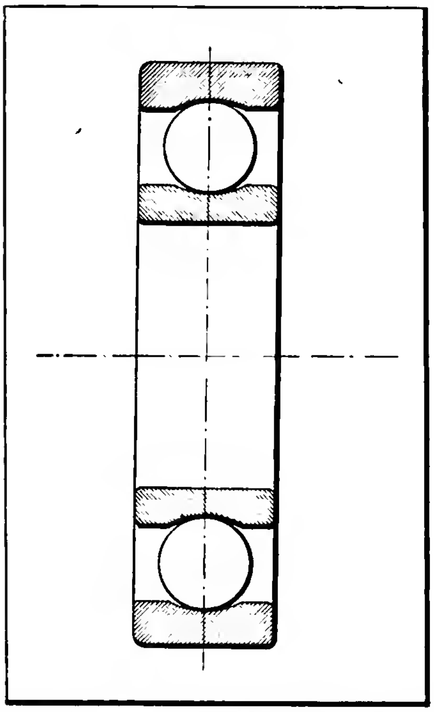

Fig. 5—Showing an annular type ball bearing and the correct position of the outer race when it is not interfered with.

In the types of bearings as illustrated in Fig. 6, when they are removed and cleaned it is desirable to inspect the spring separators and ascertain if they are in good condition. They should be sufficiently elastic to take up all lost motion, and if they are not, the best thing to do is to replace them by new spring separators, which can be made by a man of some deftness, or replacements may be had from the maker.

Figs. 1 and 7 are offered to show the difference between right and wrong when a plurality of bearings are correlated; that the shaft, if it is long, will deflect is a certainty, and in Fig. 1 it will be seen that the condition established is one which will cause the bearings to be pinched if the shaft does not deflect. Fig. 7 presents a design which is a corrective for this evil, due to the curvature of the housings for the bearings. Compensation is established, since the shaft deflection, instead of resulting in the cramping of the bearings, causes motion of the bearing housing against the surface of the shell.

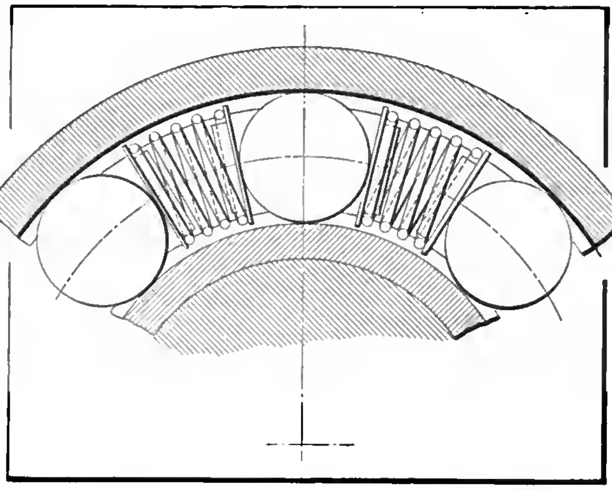

Fig. 6—Presents a portion of the silent type ball bearing, with spring spacers placed to maintain the proper distances of balls

The owner of a car who waits until he hears a squeak before he ascertains what an oil can is for is the customer whom the garage repair man relies upon for most of his income.

PROPER MAINTENANCE DEFERS NECESSARY REPAIRING

When annular types of ball bearings are used, if they are sufficiently large for the work they must do, and are provided with housings so designed that grease or other hard lubricant will be retained, the grease will have its tasks as follows:

(A) As a lubricant, it will have but little work to do.

(B) As a buffer between the balls it is worth considering, although the condition of rubbing, which is apparently indicated in Fig. 4, is scarcely worth taking into account, since the balls automatically space so that they do not actually contact after the speed reaches a certain point.

(C) The grease must serve as a preservative of the polished surfaces of the balls, and prevent rust from forming.

(D) The grease is also required in its capacity as a seal for the purpose of excluding foreign matter, as sand, fine dust, etc.

Any form of hard grease will have sufficient lubricating property (unctuousness) to satisfy the condition (A). The condition (B) is readily satisfied by any form of grease, or even oil, which will coat over the surfaces, especially of the balls, and serve as a cushion. The condition (C), however, is much more exacting. Any form of grease which holds in its composition such compounds as will attack and etch the polished surfaces is of the greatest detriment to the balls and the races.

It is frequently claimed that oil or grease which is the product of animal or vegetable matter is acid-producing under certain conditions, or may have free acid in its makeup. There is a certain amount of truth in this story, and in selecting lubricants which are made from animal or vegetable matter, it is necessary to exercise care, and it may even be desirable to consult the makers of reliable lubricants of this character, and procure from them the types of their products which are free from etching proclivities. This is not by any means a difficult task.

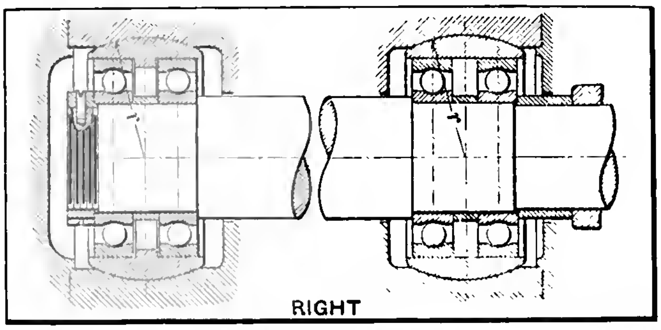

Fig. 7—Shows the right method of assembling dual ball bearings at the two ends of a long shaft.

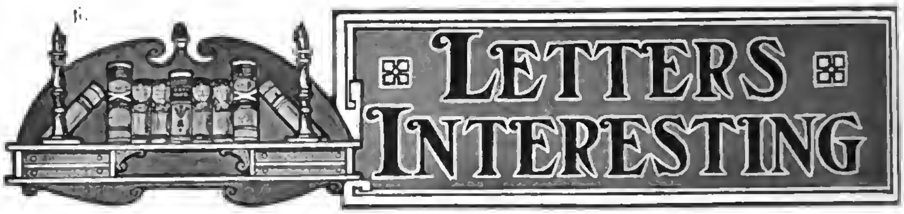

A QUESTION OF LIABILITY

Editor THE AUTOMOBILE:

[2,160]—Kindly answer the following through the columns of your valued paper. If you can cite any legal authorities that cover this matter, do so. A is driving his car on a dark, rainy night, has top and windshield up, and is using second speed. The streets are poorly lighted and rain has covered the glass front so that it is impossible to see out. Driver is on the left hand side of the car track going south, and getting to a corner where he wishes to turn east. At or just before the corner he runs into a buggy. The first knowledge he has is the crash. When looking out he sees the buggy on one side and then on the other a horse breaking away. Car is stopped within three feet and levers show second speed. Man with buggy was looking for street car and claims he did not see machine until crash came, but saw it in time to throw horse off to east side of road to escape having it hit by the car. Light on front of car, left side, had been lighted, but was put out without knowledge of driver either before or after crash, or else at the time of the accident. Driver found man was thrown forward when horse broke away and hit his nose on dash of buggy, breaking bone, he claims. Query: What liability attaches to driver of car and what to driver of buggy? Automobile had lamps smashed and was otherwise injured. It was a pure case of accident, with no intentional injury. Driver of automobile rendered all possible assistance to people in buggy. Is he liable? If so, for what amount? And, in fact, would it be anything at all, or anything beyond actual repair to buggy and medical service. FRANK COOK.
Des Moines, Ia.

Although it is not anywhere so stated, we take it that the driver of the buggy was on the east side of the road, proceeding north, that is on his right side as he should be. The driver of the automobile, on the other hand, was on the wrong side of the road, simply as a matter of personal inclination or convenience, as the letter puts it, "he is getting to a corner where he *wishes* to turn out." In doing this he violates the rule of the road and drives on the wrong side. If in the course of such driving, as in the case cited above, he meets and damages a rig, whether another automobile, a horse-drawn vehicle, or any other, does not matter in the least. He (the automobilist on the wrong side) is liable not only for all repairs, but also for damages in the case of personal injuries, which the law usually considers as more than the cost of actual medical assistance. There is not a single thing that can be said in favor of the automobile driver's position in this case, the night in question being the very last one on which a sensible driver should try such a short cut. As the matter stands, the driver of the automobile was wrong from start to finish and should settle at the other man's terms. Apparently, no blame whatever attaches to the driver of the buggy.

PROPER GEARING FOR STEEP HILLS

Editor THE AUTOMOBILE:

[2,161]—I have an Oakland "20" 1909 car, which seems to lack power on hills, and particularly in deep sand, of which we have a lot in this part of the country. On ordinary roads the car runs fine, and I can find no fault, but some of the hills up this way are very steep and long. Then, too, there are lots of them, so that the car is in trouble often. It is a two-cylinder 4 1-2 by 5 engine, planetary transmission, shaft drive, and geared to a 4 to 1 ratio. Can you offer any suggestions whereby I could get more power out of my present equipment? Could the 4 to 1 gears be changed for a set of 5 to 1 gears without changing the bearings? Can you give me the address of the Warner Gear Company, who were the makers of the gears on my machine; at least I think so? MORE POWER.
Florence, Wis.

From the description which is given and the knowledge we have of the usual performance of these cars, we are forced to the conclusion that the trouble is with the gearing used and the surrounding country, rather than with the engine. Although it will depend entirely upon the dimensions of the differential gear housings, of which we do not have the figures, the change from 4 to 1 to 5 to 1 is otherwise feasible. If it should be found that this change is impossible, why not make a smaller change, such as to 4 1-4 or 4 1-2 to 1 in place of the present gearing? Even the slight change first suggested (4 1-4 to 1) changes the speed of the car, lowering it by 6 1-4 per cent, and raising the hill climbing and pulling ability by the same amount.

In making the change, it will be found that the lessened speed is not any too agreeable, so that it is wise to lower the gear ratio as little as is necessary to secure the hill-climbing ability required.

The Warner Gear Company, to whom you have reference, is located at Muncie, Ind., where they should be addressed.

HORIZONTAL AND VERTICAL ENGINES

Editor THE AUTOMOBILE:

[2,162]—I am very much interested in stationary engines of the four-cycle type, and would like to have you state a comparison between the vertical and horizontal types, giving the advantages and disadvantages of each. What are the proper angles on the crankshaft for the various places of beginning and ending the valve actions and firing operations? Will you please explain the low-tension ignition system as used with the Splitdorf single unit coil and magneto for four-cylinder work, as on the E-M-F car, for instance? L. GEE.
Whitehall, Mich.

In general, the comparison of the two types of stationary engines is based upon the matter of saving of space, both vertically and horizontally. It is considered that in the usual power plant there is sufficient height for any purpose, while the floor area is limited. If then two engines of equal power occupy respectively 8 square feet of floor space by 6 feet high, and 36 feet of floor space by 3 feet high, there is hardly any doubt as to which one will be chosen, height being cheap, while floor space costs money. As to other considerations, the only one worthy of devoting space to is the matter of valves and valve location. On the horizontal engine the valves are usually placed horizontally and bear on a vertical seat. Gravity acting upon the valve tends to make it wear the seat more on the lower side than the upper, thus leading to frequent regrindings, and trouble with leakages in between grindings. The vertical engine, on the other hand, has the valves vertically and the seats horizontally. The action of the weight of the valve and the strength of its spring are both acting all around the surface, no one part being worn more than another. This small difficulty is overcome by some makers of horizontal engines by setting the valves vertically, in which case the choice between the two types becomes a matter of available floor space and its value.

As to valve settings, opinions differ, but an average valve setting would be (all measured upon the crankshaft): Inlet opens at 10 degrees past center and closes at lower center or 10 to 20 degrees past. Compression from this point to upper center. Fire at small angle past, angle varying from 15 degrees for starting back to dead center for highest speed. Open exhaust valve beginning at 30 degrees before end of power stroke, holding it open up to the upper center and 5 degrees past. Interval of 5 degrees, then open inlet valve again and repeat.

If the magneto and ignition system is understood exactly as it is meant, the magneto generates a low-tension current which is sent through the coil, to be stepped up to a high-enough voltage to jump the spark plug gap. In place of using a single vibrator for each section of the coil, but one is used, and all coil parts wired through that one. It must then vibrate just four times as fast as any single vibrator in the ordinary system, in which four vibrators are used. Otherwise the whole system is the same as any other so-called high-tension ignition system.

CASTOR OIL AND RESIN CEMENT

Editor THE AUTOMOBILE:

[2,163]—Would castor oil and resin make a cement to fasten canvas inside tire shoes? Has it ever been tried? W. T. K.
Nichols, Conn.

The cementing qualities of this mixture are hard to determine, although, as a matter of fact, neither one of them has any cementive properties worth mentioning. Castor oil won't stick to anything (not even to the human stomach) and similarly resin is a poor binder. Answering your last question, we have never heard of its being used, either one of the constituents or the compound. In preference to this muss, why do you not use one of the many excellent cements now on the market for this purpose?

Answered and Discussed

A MULTIPLICITY OF BROAD QUESTIONS

Editor THE AUTOMOBILE:

[2,164]—Please answer some or all of the following questions in the columns of "The Automobile" and help an interested subscriber: 1. Why can you not have the greatest speed and greatest gasoline economy at one and the same time? 2. When was the Knight patent on a sliding sleeve engine issued? 3. Is the Ledru type of rotary sleeve engine patented; if so, when? 4. In a worm drive, using a driven worm of 5-inch diameter, and a small worm driving it, with teeth of a high pitch, what is the greatest reduction possible? 5. I have a good theoretical knowledge of automobiles and want to get a position at some factory in Detroit. What could I do and how should I proceed to get into touch with some of the factories there? C. W. S.
Albany, Ind.

Greatest gasoline economy is obtained by a very weak mixture, this reducing the amount of fuel used. Greatest speed on the other hand is obtained by a fairly rich mixture. So it is that the two may not be had simultaneously. If you refer to racing engines, these are usually constructed so as to obtain the maximum speed regardless of fuel consumption.

The Knight American patent has not yet issued, but is doubtless now in the Patent Office, which, however, is just as much protection to the inventor as if it had actually issued. The Ledru engine has not been patented on this side, but may possibly be patented in France.

Speed ratios or speed reductions as afforded by worm gearing vary with the number of teeth in the worm wheel and the threads of the worm. Then, if you fix the teeth in the driven wheel, the number of threads determines the speed reduction. Thus, if the single thread is used and gives a certain reduction, using a similar worm, but with a double thread, doubles the reduction. This may be carried on to the triple, quadruple and quintuple worms, the forms now in regular use. The pitch angle is usually fixed by considerations of economy, the proper angle resulting in an efficient power transmitter, while the wrong angle, either too large or too small, gives very inefficient driving, and consequent loss of power. The efficiency curve is flat topped, the efficiency with a 10-degree angle reaching about 80 per cent. Rising slightly above this in between, it comes down to the same point (80 per cent.) for a 78-degree angle. The actual maximum is reached at 45 degrees.

Nearly every factory in Detroit is at present seeking help in one department or another, so that a letter addressed to any one company will doubtless bring an immediate answer.

LEFT-HAND DRIVE AND WIDE TREAD

Editor THE AUTOMOBILE:

[2,165]—Will you furnish me with a list of all American cars which are now built with both left-hand drive and 60-inch tread for Southern roads? J. H. HODGES.
Gainesville, Fla.

Unfortunately for a direct answer to your question very few makers turn out a car with both features, although the number turning out each one of these separately is rather large. Thus the following make cars with 60-inch tread: A. B. C., Badger, Brush, Buggyaut, Cadillac, Cameron, Cartercar, Chalmers-Detroit, Cole, Cutting, E-M-F, Eureka, Flanders, Ford, Great Western, Hupmobile, Maxwell, McIntyre, Mitchell, Rambler and Reo. Of these only Brush, Ford and Reo have left-hand control, so that, as an exact answer to your question, the latter three are all that would be given.

Recent developments would seem to indicate that the left-hand drive is gaining in favor. The above list must not be taken as final for no attempt has been made to enumerate the cars which are driven from the left, but do not use wide tread. They are many.

CONE AND DISC CLUTCHES

Editor THE AUTOMOBILE:

[2,166]—Please discuss in your questions column the relative merits of the cone and multiple disc clutches. Which is the better clutch? Which is the better multiple disc clutch, the dry one or the one running in oil? J. M. I.
Cleveland, O.

Such questions remind one of the old friend, "How old is Ann?" Or, to put it otherwise, the return question might be asked, which is better, a silver dollar or a dollar bill? That about expresses the idea, it being impossible to state for a certainty that any one form is the absolute superior of all others. Each form of clutch has much to recommend it and, perhaps, a few faults. It noticing what the great majority of manufacturers are using as indicated by some such table of specifications as that to be found in the Chicago show issue of THE AUTOMOBILE, some idea may be had of popular demands. This, in reality, is what is turned out, without any idea of a "best." Actually, this is not so very far from an all-around best, for a majority of people would not want any one form if it did not have more commendable and less censurable features than the others.

So, too, with the second question, this is like asking which is better, a new silver dollar or an old one. The dry disc clutch has a number of advantages so weighty as to call for its adoption in the face of the reasoning that a clutch holds through friction, which means wear, the latter usually being reduced by the use of a lubricant. Up-to-date practice as expressed in percentages would tell an interesting story in this connection.

POINTERS ON PROPER TIRE INFLATION

Editor THE AUTOMOBILE:

[2,167]—All owners of automobiles as well as the trade will be interested in tests recently made at the factory of the Diamond Rubber company in Akron, with regard to the use of gas for inflating automobile tires as compared with the use of air.

The tests showed that gas in place of air will do for inflation of tires, if the user will but watch his tires and replace gas which escapes. But right here is the troublesome point. Not all owners watch their tires carefully enough, and even for those who do it is almost impossible to notice the constant leakage that goes on when gas is used. In one way or another gas will seep out of the tires by imperceptible degrees and more rapidly than air, as the Diamond Rubber Company's tests have shown the leakage of the best gas-filled tire was 43 per cent. greater than in any one of the air-filled tires.

The tests also served to emphasize the need of ample inflation of tires whether it be by gas or by air.

At the plant of the Diamond Rubber Company three tires were pumped by air to 100 pounds pressure each at 1:30 P. M. on October 14. At the same time three tires of the same size were inflated wtih carbonic gas to the same pressure. A week later, October 21, at 1:30 P. M., the three air-filled tires registered 92 pounds each, while the three-gas-filled tires stood 41, 50 and 51 pounds.

Should an owner pump his tires to 100 pounds with carbonic gas and not have a noticeable puncture he is likely to take for granted even a week later that he has been running with sufficient inflation. As a matter of fact, he really has only half enough, and during the intervening time considerable damage may have been done to the body of the tire.

The meat of these recent tests, previous tests and of many years of experience can be summed up in one terse sentence: Tires must be pumped up hard if they are to give maximum mileage. Speaking on this point Mr. Weigele, of the Diamond Rubber Company, said: "There is only one sure way of properly inflating tires so that they will give the most service of which they are capable, and that is to keep them pumped up so hard that they stand up full and round under a maximum load when in motion. If this is done there will be a decided increase in tire mileage.

The element of friction and heating is reduced by ample inflation, which also checks the movement within the tire and enables you to ride, as you should ride, on a cushion of air and not a cushion of rubber. And in this connection it is just as much the duty of the user to supply plenty of air as it is of the producer to supply good tires. Each expects the other to do his part, and the co-operation should be of mutual benefit. It will result in a reduced upkeep cost that must ultimately be of great benefit to the automobile industry.

Users should watch their tires, and when they do not stand up round under a full load, should immediately supply new air. The one safe rule is to do this at once, remembering that pressure gauges do not provide for the over-loaded tire, and four-fifths of all tires are frequently overloaded. The best available answer to the overloaded tire is the size of tire next larger than that usually applied. The only answer of any other kind is that of air, and still more air, and nowhere do the results show faster than in the service given by the tire overloaded as a regular thing.

Another thing that should be constantly kept in mind by the automobile owner is not to wait until all four tires are in need of air before using the pump. Don't let one tire get partially deflated and run your car in that condition. Not only is the effect very bad on the deflated tire, but the other tires are subjected to extra work that can only work injury to them.

Keep your tires pumped up hard—all of them—all the time.
Akron, O. JOSEPH W. CONNER.

Preheating the Mixture in Gasoline Motors

By Forrest R. Jones

PREHEATING the mixture of air and gasoline vapor just before it enters the cylinder or cylinders of gasoline engines and a full discussion of the good and bad effects of the practice will be the subject of this article. Only incidentally the preheating of the air before it reaches the carbureter, and the warming of the carbureter by means of a jacket or hot water or hot air around the vaporizing chamber is brought into the discussion.

In the monobloc type of multi-cylinder motor, with all cylinders cast in one piece, it is quite common practice to adopt a design in which the inlet ducts, or passages, for the ingoing charge, and those for the escaping exhaust gases, are all on one side of the cylinders and immediately adjacent to each other in the casting. A portion of the walls of the exhaust ducts are also a portion of the walls of the inlet ducts in some of these designs.

Some of the heat that is received from the exhaust gases by the metal forming these walls is therefore transferred to the ingoing charge of mixture just before it passes into the combustion chamber. The amount of heat that is thus transferred from the exhaust gases to the ingoing charge depends largely on the surface area of the metal wall that lies between the exhaust and inlet ducts. The heat is transferred more rapidly through a thin wall of metal than when it must pass a considerable distance through the metal. The compactness of the casting containing the ducts, which may be called the duct-box, also has to do with the rapidity of the transfer of heat from the exhaust gases to the ingoing charge. When the duct-box is very compact more heat is thus transferred than when it is of less compact form and the ducts are not so close together.

Lack of Preheating Causes Cooling, Even Frost—It is of course well known that when a carbureter without any hot-water or hot-air jacket is operated on air taken at atmospheric temperature, the carbureter becomes decidedly cool, especially just beyond the spray nozzle or other form of gasoline outlet into the air passage. In other words, the walls of the mixing chamber become very cool. The pipe connection from the carbureter to the motor also becomes cool at the end next the carbureter. In some cases the carbureter is cooled to such an extent by the vaporization of the gasoline that frost collects on the outside of it in damp weather, even at summer temperature.

In damp, cool weather it not infrequently happens that frost and ice collect in the mixing chamber so as to clog the passage and prevent the operation of the throttle valve. The cooling of the carbureter is more marked in connection with motors having several cylinders than in those having only one, since the vaporization is carried on more continuously when several cylinders are fed by one carbureter than when only one cylinder is fed.

Two methods of prevention came into use to keep the carbureter from freezing up. These have already been mentioned. Specifically, one method is to surround the mixing chamber, and sometimes also other parts of the carbureter, with a jacket of hot water, or hot air, from the motor; the other method is to heat the ingoing air before it reaches the carbureter, this preheating being accomplished by causing the air to come into contact with some warm, or hot, portion of the motor before reaching the carbureter.

It may also be noted that heating the carbureter, or preheating the air, or both together, affords a means of using what are commonly called inferior grades of liquid fuel, which are now so common; even ordinary kerosene can be used in this manner after the motor has become heated by running for some time.

After the liquid fuel has become vaporized and mingled with the air to form a combustible mixture, there is no probability that it will condense to a liquid during the operation of the motor. To condense it the mixture would have to be cooled below the temperature of the mixture when first formed, or it would have to be compressed without allowing it to become warmer on account of the heating action of compression. In the case of gasoline it would have to be compressed to a far higher compression pressure than is used in automobile motors, even if cooled by some means during compression so that its temperature would not rise above that at which the mixture left the carbureter.

All Fuel Vaporizes Close to Carbureter—The manner in which a motor operates is evidence that the gasoline, even if of low grade, vaporizes completely within a few inches of the spray nozzle of the carbureter. Even if the inlet pipe is long, so as not to have a considerable length not warmed appreciably by the heat of the motor, it is not cooled anywhere near as much at the part at some distance from the carbureter, as the latter and the portion of the pipe immediately next to the outlet of the carbureter are cooled.

If the vaporization were not completed near the carbureter it would be continued through the pipe, and the latter would be cooled very decidedly at the portion in which the vaporization continued. The fact that the inlet pipe does not become near as cold as an unjacketed carbureter when the air is not preheated is evidence that the vaporization is completed at or near the carbureter.

Naturally, the next question that arises is, does preheating a combustible mixture effect any economy of fuel or any increase of power? All of the know properties of gases and all of the known results of practice go to show that it does not.

First, as to the power developed in the cylinder of the motor. In a given motor the amount of power developed is at least approximately proportional to the weight of the charge of combustible mixture. The weight of the combustible mixture is proportional to the weight of the air in the mixture, assuming that the moisture in the air, or humidity, remains constant.

Volume Invariable, Temperature Changes—The volume of the charge taken into the cylinder is, of course, always the same for a given setting of the throttle and speed of the motor. This volume is approximately equal to the displacement of the piston per stroke. The piston is always at the same position when the inlet valve closes, at least in a motor with mechanically operated inlet valves, so that the same volume of charge is always enclosed in the cylinder at the instant the inlet valve closes. The pressure in the cylinder at this instant is always the same for the conditions just stated.

Every charge taken into the cylinder therefore has the same volume as measured in the cylinder, and the same pressure, both taken at the instant the inlet valve closes, as long as the speed of the motor and the setting of the throttle remain unchanged.

Weight of the charge varies with its temperature, since heating the mixture expands it if the pressure is kept constant. A pound of air at 62 degrees Fahrenheit and atmospheric pressure has a volume of about 13.14 cubic feet; when heated to 212 degrees, which is the temperature of boiling water in the open air, its volume is increased to about 16.9 cubic feet if the pressure is kept the same. It is therefore clear that a less weight of mixture is drawn into the motor cylinder per charge when the mixture is hot than when it is cool.

The smaller the weight of the charge, the less the amount of heat produced by its combustion. The amount of heat produced is proportional to the weight of the charge, when the proportions of air and fuel in the mixture remain constant, which is in accordance with the operation of the motor. A carbureter which operates correctly delivers a constant mixture.

Power Per Weight Proportional to Pressure Increase—The amount of power that a given weight of fuel will produce in a combustion motor when properly mixed with air and burned is approximately proportional to the increase of pressure that is caused by the heat of its burning. It has been clearly demonstrated experimentally in very recent years that the heat from a given amount of fuel will increase the pressure more when the temperature of the mixture at the instant of ignition is low than when it is high.

This is true even when the combustion is effected in a containing vessel such that the cooling effect of the walls is no greater at a high temperature than at a low temperature. This is contrary to the older theory of the action of combustion motors, and is apparently not yet fully understood by those dealing with such motors. The old theory is that the combustion of a given amount of fuel will always cause the same amount of increase of pressure whether the initial temperature is high or low, provided no heat is given up to the walls of the containing vessel. This theory has been conclusively proven to be untrue. The cooling action of the walls of the cylinder and combustion chamber is, of course, greater when the charge is hot than when it is cool. The motor does not therefore develop as much power in the cylinder, and the economy of fuel is less when the entering charge is hot than when it is cool.

Another disadvantage of heating the charge before it enters the motor cylinder is that it cannot be compressed to as high a pressure before ignition as a cooler charge can be. This is because it will ignite spontaneously at a lower compression pressure on account of its higher initial temperature. It has long been well known that efficiency of operation is increased by increasing the compression pressure within the limits of compression pressure that is practicable in automobile motors.

Advantages of light weight, fewer parts, lower cost of construction and possibly less power lost in the motor by driving its moving parts lie with the more simple motor which has a small and compact duct-box containing both inlet and exhaust ducts. These are strong points in favor of such construction. The best compromise seems to be this form of construction with water jackets enclosing the exhaust ducts as completely as possible.

The slower the speed of the engine during normal running conditions, the lesser the influence of preheating the mixture, whether this be favorable or otherwise. It is for this reason that little or nothing on this subject, so interesting to automobile owners and drivers, is to be heard among the motor-boat contingent. They talk little of it because its influence is so slight in their business or pleasure, as the case may be, as to be entirely negligible. The greater the speed of the engine, the more desirable is preheating, making it imperative for racing machines.

WESTINGHOUSE EQUIPMENT FOR ELECTRICS

COMPLETE motive equipments for electric vehicles of all descriptions, as manufactured by the Westinghouse Electric & Mfg. Co., are illustrated by the exhibit which is making the rounds of the shows under that company's name. The illustration shows the table carrying the motor, controller and voltammeter.

The motor is of the regular vehicle type known as V-28, for 48 volts, and is very similar to the street car motors which the company has made for over a score of years. The controller, type 501-D, is equipped as in service with a grid-starting resistance, both forward and reverse notches of the quadrant being connected up. It is provided with an interlocking device, so that it is impossible to operate it incorrectly.

Current is supplied from a set of regular automobile type batteries, not shown in the photograph. The motor can be run in either direction, and loaded by means of a double prony brake, taking the place of the regular armature band brake for vehicle service. By turning one or the other hand wheel, the friction of the brake may be varied, and the current required and the voltage at which it is supplied are instantly shown on the meter.

The switch has three positions—off, running and charging—and is designed so that the key for operating it can only be inserted when in the off position, and cannot be removed until the switch has been returned to this position. This prevents any possibility of mistake either in charging or operating.

The standard vehicle voltammeter shown with the outfit permits the operator to read the voltage of the batteries at any time, determining thereby their condition and the approximate amount of charge. The current may be read when either running or charging.

CHARACTERISTIC CURVES OF INTERNAL COMBUSTION MOTOR

By B. D. GRAY

A COMBINATION of horsepower and torque curves with relation to angular velocity of crankshaft or piston speed, or, what is still better, total displacement per minute, will, I believe, give the most comprehensive measure of the performance of a motor and serve satisfactorily as a means of comparison.

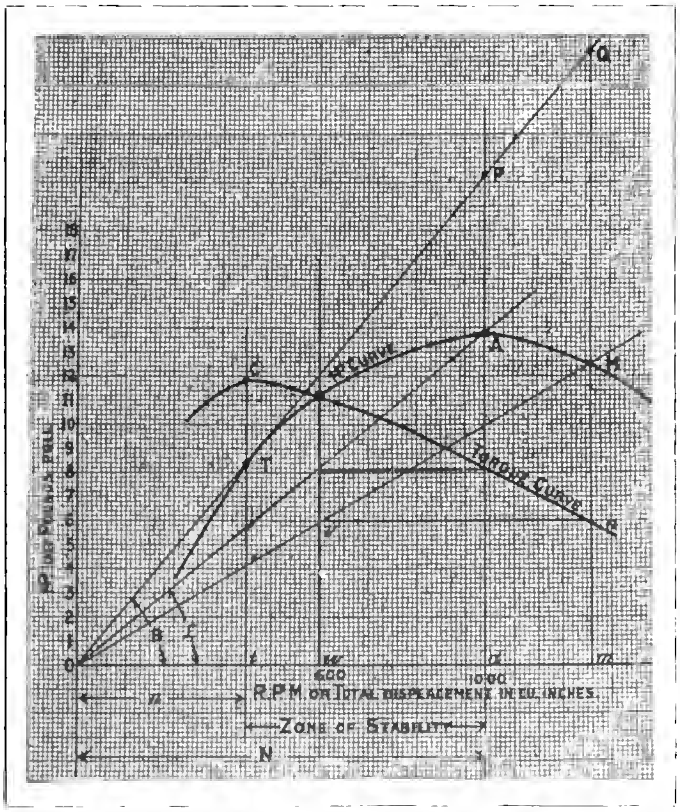
As is well understood, such considerations as type of motor, amount of compression and other details of design have no place in the discussion on this subject, although they are all important factors in the attainment of results, which it is proposed to illustrate by characteristic curves, and they enter, therefore, into the problem which confronts the designer of producing the most harmonious combination.

Mechanical efficiency has an important bearing, but I think it must also be relegated to the realm of the designer.

Thermal efficiency has, perhaps, a more intimate relationship with this subject, but it cannot properly, of itself, be made a prime factor in the determination of horsepower and torque curves.

Fuel consumption has a very decided bearing, and it may be argued that many purchasers give as much consideration to this feature as to flexibility, and that, therefore, provision should be made for a curve which would show the amount of fuel consumed, either per horsepower-hour or total, throughout the entire range of the motor. This would complicate matters, since, while it is perfectly feasible to add to the diagram given below, a third curve showing fuel consumption, it could be plotted for one condition only, viz.: Full load at varying speeds. It would be preferable, therefore, to consider separately the question of fuel consumption and efficiency.

Under present commercial conditions I believe that flexibility is the most important consideration, and desire, therefore, to direct the attention of the members to the accompanying diagram, which was published some months ago in "Omnia," in connection with a very interesting article on "Flexibility of Automobile Motors." In this diagram, both the curve of power and the curve of torque are plotted with a line representing flexibility.



Superimposed Curves of Power, Torque and Flexibility

"Graphic representation of flexibility of motor" $\frac{Pa}{Aa}$ represents flexibility of motor at normal speed N. $\frac{Qm}{Mm}$ represents flexibility at speed Om.

The H.P. and torque curves may be plotted geometrically one from the other without calculating each point. Joint point M on H.P. curve with O point. The triangle OMm gives tang. $\alpha = \frac{Mm}{Om}$.

Mm represents the H.P. at speed Om. Therefore, the quotient of the H.P. and R.P.M. equals the torque; that is, tang. α represents the torque, which is, therefore, measured on the diagram by uv. Carrying uv to the ordinates Mm the point n is obtained, representing the torque at speed Om. Note that maximum torque is obtained when α is maximum; that is, when the line Om is tangent to the H.P. curve, and the torque curve indicates that the maximum torque is at C (where the tangent is horizontal). The H.P. is maximum at A. Between n and N, corresponding to C and A, is the "zone of stability."

It is interesting to note in what way the information thus obtained regarding the performance of a motor may be utilized in determining the gear ratios of an automobile.

Gear reductions in transmission should be so designed that speed changes will keep the motor within the "stable zone," *i. e.*, as resistance increases and motor speeds decrease to n a change to the next lower gear will permit a motor speed of N without change of vehicle speed. Hence neither racing nor stalling of motor.

Flexibility of the motor is represented by $s = \frac{N}{n} \times \frac{w}{W}$.

N = the normal speed.
W = the maximum power.
n = R.P.M. which gives maximum torque.
w = power corresponding to speed giving maximum torque.

Theoretically gear reductions should be as follows:

v_1, $v_1 \times s$, $v_1 \times s \times s$, $v_1 \times s \times s \times s$, hence the reason for geometrical progression. On account of air resistance the high speeds must be less than gear reductions indicated.

Considering the H.P. curve and taking the tangent from the origin O, the right-angle triangles OPa and OTt give:

$$Pa = \text{tang } \beta$$
$$Aa = \text{tang } \alpha$$
or
$$\frac{Pa}{Aa} = \frac{\text{tang. } \beta}{\text{tang. } \alpha}$$

It is known that the tangents measure the torque and that the ratio of the torques considered represent the flexibility of the motor; hence $\frac{Pa}{Aa}$ represents the flexibility. The flexibility is always greater than unity, usually varying from 1.2 to 1.5. It should be possible to obtain a flexibility of 1.6. In actual practice the apparent flexibility is increased by racing the motor before shifting to a higher gear. This is represented on the curves by Om, representing a speed greater than N. If speed changes are made in this way s becomes $\frac{Qm}{Mm}$.

REMARKS RELATING TO GEAR AND PINION FAILURES*

By GEO. WM. SARGENT

IT IS not the purpose of this paper to go into the subject exhaustively, but merely to bring to your attention some of the points and facts which have come under my observation. If by so doing a discussion and investigation into the causes of gear and pinion failures can be started, more exhaustive developments are sure to follow, and this effort will have some merit.

Failures in general may be traced to one or more causes:

First—Improper design.

Second—Selection of material not suited to the purpose.

Third—Improperly manufactured material.

Fourth—Improper treatment of material.

Fifth—Conditions arising in service.

In this paper improper design only will be considered.

Actual faulty design is not a rarity. The matters of gear design and strength do not seem to rest upon the same safe mathematical basis as girders, beams, columns, etc., such as are used in bridge and structural engineering. Kent's Mechanical Engineer's Pocket Book refers to six elements and intimates of others entering into the construction of a formula from which the strength of the toothed wheel could be calculated. Again, according to Professor Harkness, the power transmitted by a given pair of gear wheels varied from 1 to 15, according to the various constants and formulas then extant (1886). This remark, however, refers more particularly to gear design. Having in mind efficiency for the transmission of power, but if the efficiency is lowered the power is consumed in the gear to the detriment of the latter.

Wilfred Lewis advises that in figuring the strength of a gear the tooth should be considered as a beam loaded at its extremity and supported at its base; and, furthermore, that one tooth carries the entire load distributed across its face. Right here I wish to emphasize this last. It is exceedingly important that the load be distributed across the face of the entire tooth and this is a condition which is very hard to obtain on some instances; for example, beveled pinions and gears. In these cases, even though the design of the pinion is correct, and the strength all that is necessary under correct alignment, the concentration of the entire load upon one portion of the face of the tooth of the gear, which would follow disalignment, would result in failure.

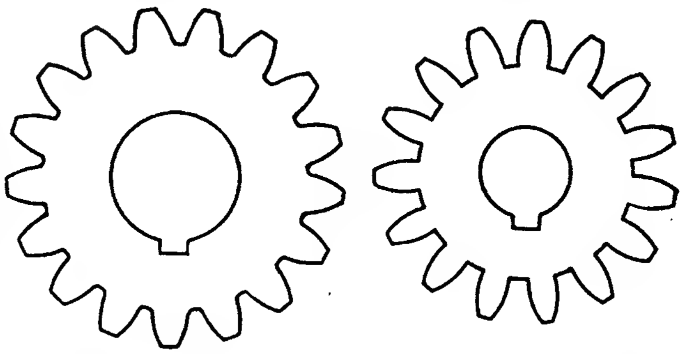
We find in "Elements of Machine Design," under the heading of "Influence of the Form of the Tooth on Its Strength," Professor Unwin remarks: "It will be seen presently that the teeth tend to break across at the root. The teeth are stronger the shorter they are, and the thicker they are at the root. They cannot to be shortened without reducing the arc of contact, and their length should be such as to ensure a sufficient, but not excessive, arc of contact. The thickness at the root depends on the form selected for the teeth. Involute teeth are generally stronger than cycloidal teeth, the teeth are stronger the smaller the diameter of the describing circle used for the flanks. In no case should the flanks be described with a rolling circle, the diameter of which is greater than half the diameter of the pitch line, inside which it is rolled."

I have already referred to Lewis' formula, in which the tooth is considered as a beam loaded at one end and supported at its base. The teeth, therefore, should not be longer than is necessary to give the desired form in order that any loss of power may be a minimum. Furthermore, with a full-sized tooth there is a strong tendency toward under-cutting, which weakens the tooth at its most critical part. Figs. 1 and 2 illustrate this point.

In automobiles, all transmission gears are subjected to a heat treatment and most spur gears are made of the hardened and tempered types of steel. In these latter the under-cut produces an effect similar to a groove or notch; for in the hardened and tempered piece it produces a temper line at the groove or notch and this temper line may develop into a plane of weakness. In pinions this under-cut condition is more likely to occur, for here the number of teeth are fewer, consequently the difficulty of forming the tooth without an under-cut is increased. A 13-toothed pinion will show more severe under-cutting than a 15 or 17-toothed pinion; and in designing pinions and gears this fact should be borne in mind, especially since the work which the pinion has to do is frequently the most severe of any part of the transmission. Again where the width of the tooth of the bevel pinion and gear at the addendum-circle is greater than at the root-circle, the effect of heat treatment is to make the overhanging end or ends harder and more brittle than the rest of the tooth; so that any extraordinary severe stress or shock is bound to cause a break at the overhanging part.

Generally speaking, all gears which are to be heat-treated should be so designed as to lend themselves to the conditions accompanying or resulting from such treatment; for instance, the sections of the various parts of the gear should be, in so far as it is possible, of uniform dimensions, so that in heating, no one part will heat faster than another, thus warping the gear. Likewise in quenching uniformity of dimensions prevents unequal cooling and hence warpage or distortion.

When it is recalled that at 700 degrees Centigrade a steel with 80,000 pounds tensile strength at the normal temperature possesses but 1,000 pounds and an elastic limit likely less than one-half this amount, it will be seen that 3 degrees difference in temperature is sufficient to produce a permanent change in the piece, and a design, therefore, which permits one part of the piece to heat or cool more rapidly than another is to be avoided as much as possible if distortion or warpage is to be reduced to a minimum. In the nature of things, this distortion of a heat-treated piece of steel cannot be eliminated, but it can be brought to the least possible amount, and should be, since warped gears are noisy and likely to break. When one recalls that hardened steel has little or no ability to flow when strained beyond its elastic limit, the necessity for a correctly proportioned gear is more appreciated.



Proper Form of Wide, Strong Gear Teeth and Improper Teeth

Furthermore, sharp corners or edges and sharp re-entrant angles should be avoided in any heat-treated piece of steel, since such design is not only naturally a weak one, but also prone to have developed, through the treatment, temper lines which may readily become planes of weakness.

Having now called attention to some of the points involved in gear design from a metallurgical point of view—and this should be noted for there is no pretension to pose as an expert in gear design—the consideration of the remaining causes of gear failures referred to in the first part of this paper will be made at a later time, for each in itself involves so many points that it would seem best not to attempt to cover them all.

*Paper read at the semi-annual meeting of the Society of Automobile Engineers, New York City, January 4 and 14, 1910.

RECENT CLUB ACTIVITIES

QUAKER CITY'S GOOD ROAD WORK

PHILADELPHIA, Jan. 31—That there are numerous avenues of usefulness open to the up-to-date motoring organization when roads are blocked with snow was made manifest last week when the Quaker City Motor Club began the distribution of a pamphlet. This contained the constitution and by-laws of the East Whiteland Township Improvement Association and a history of how it does its work of improving roads within its particular bailiwick.

The Quakers are especially interested in this small subdivision for the reason that a number of its most prominent members have summer homes in the immediate vicinity and because the much-traveled Lancaster Pike bisects the township from east to west. The Quakers argue that if the road supervisors of other townships can be similarly interested a vast chain of road-improvement projects will be launched which will benefit not only the automobilists, but the farmers and the property owners along the improved highways.

The rusticating Quakers had long deplored the poor condition of the Pike, and President Ross and Frank Hardart, whose properties abutted on it, determined to bring about a change. They interested the road supervisors—Messrs. Morris, Templeton, and Thomas—and later the project of organizing the East Whiteland Township I. A. was put through, whose object can be summarized under the following heads:

First. The improvement of the roads and the township.

Second. To encourage the improvement of the roads in neighboring townships and throughout the county.

Third. To promote and encourage local and neighborhood improvements, public and private.

Fourth. To discuss all matters pertaining to the public good and encourage all enterprises that would increase the value of property or improve in any manner the condition of our citizens.

Upwards of $20,000 has been spent on the township's roads, and there is a comfortable balance to open the roads in the event of snow blockades—which, by the way, came in handy during the Christmas blizzard—or other emergencies.

The Q. C. M. C. is of the opinion that similar results can be obtained in other communities, and is mailing the history, constitution and by-laws of the East Whiteland T. I. A. broadcast in the hope that the seed may fall upon fertile ground and similar benefits follow.

JUST BROKE MEMBERSHIP RECORD

SYRACUSE, N. Y., Jan. 31—The Automobile Club of Syracuse succeeded in its determination to have 400 members by the end of the year, and with 5 to boot, at that. The end was almost gained in a meeting held December 22, when 25 new members were voted in, but the figure still remained a trifle short of the mark which had been set. So the officers got busy, and on Thursday of this week held another meeting when 13 more were voted in. It was a lucky number, for it completed a quota of 405 members.

This is an increase of 168 since July 1, and it represents a lot of tall hustling on the part of the officers, particularly of President H. W. Smith and Secretary Forman Wilkinson. The assistant secretary, Miss Grace Tickner, has also hustled some toward this end. The officers now say that nothing short of 100 more before July 1 will satisfy them, and they are going after the "candidates" strong. Beginning January 1 the club will issue every month a club paper, to be known as the Spark Plug. It will be the official organ of the club and will contain information to members regarding such matters as speed traps in this section, road information for short tours out of Syracuse in all directions, reports of club meetings, banquets, etc.

The membership of the club has so increased within the last year that at a recent meeting it was decided that this publication should be initiated. One object will be to keep members well posted on automobile legislation as it is introduced from time to time and the progress that is made with it.

The club is continuing its campaign for better road directions in and out of Syracuse. This week signs were sent to Elbridge, Cazenovia and Oneida Castle, at the request of residents there. There is a danger point on the State road between Camillus and Marcellus, where large signs have been placed, warning autoists to drive with care. Several accidents have occurred there, and the club was asked to send signs. There is a tunnel 200 feet long, and the road enters and leaves at an angle.

NEW HAVEN'S NOVEL BANQUET SCHEME

NEW HAVEN, CONN., Feb. 7—Novelties are promised to those who attend the second annual banquet of the New Haven Automobile Club, to be held in Harmonic Hall, that city, February 9. The banquet will have for one of its novel features the fact that it will be a speechless affair. Among other odd effects the only illumination at the dinner will be furnished by powerful auto searchlights, while the music will be furnished on an orchestral electric phonograph. The decorations will consist entirely of automobile accessories and supplies. Invitations have been sent to over 500 club members and their friends, and among those who are expected to attend are Gov. Weeks, Secretary of State Rogers, and Attorney Joseph P. Tuttle, counsel for the State Automobile Association of Connecticut.

DENVER CLUB WILL HOLD SECOND SHOW

The Denver Motor Club will hold its Second Annual Automobile Show on February 2-3-4-5-6. The Board of Governors have appointed the following on the committee: C. P. Allen, chairman; Dr. Edw. F. Dean and Wm. D. Nash, the latter president of the Denver Motor Club. Communications should be addressed to C. L. Wands, manager.

EVEN SALAMANCA HAS A CLUB

In Salamanca, N. Y., about twenty-five local automobilists met recently and organized the Salamanca Automobile Club. The following officers were elected: President, Charles R. Gibson; vice-president, George L. Hammond; secretary, Albert M. Preuner; treasurer, William H. Hazard.

ROAD BUILDINC NEWS

INDIANA WILL NOW BUILD GOOD ROADS

INDIANAPOLIS, IND., Feb. 7.—Road work in Indiana, which has been stopped for more than two months, has been resumed, following a decision of the supreme court that the road laws are constitutional. In November the same court held that these same laws were unconstitutional, but, in response to a general demand, consented to reopen the case.

The laws affected are the ones providing for highway construction and the three-mile statute. Under the former, fifty or more residents of a township having a population of 30,000 or more may petition for an improvement, the question to be submitted to a vote in the township. Bonds are then issued by the county commissioners to defray the expense and later a

NEW YORK AUTO OWNERS' LICENSE ADVOCATED

ALBANY, Jan. 31—Those endeavoring to have the owners of motor vehicles examined and licensed like a professional chauffeur will have the aid of Governor Hughes, judging from his message to the Legislature on the subject, as he says therein:

There is obvious necessity for the improvement of the regulation of motor traffic. I believe that a substantial license tax should be imposed for the privilege of operating motor vehicles within the State, the proceeds to be devoted to highway repair. But the matter of first importance for your serious consideration is the provision of adequate safeguards to protect the lives of our citizens. The operation of motor vehicles should be prohibited save by those who upon proper examination and after tests specially adapted to their work are found to be duly qualified and are licensed accordingly under proper State authority administering a system of uniform application. These licenses should be subject to suspension and revocation, and in case of repeated infractions of the law the guilty person should not only forfeit his license, but be debarred from receiving another in the future. It should be made a crime in itself, with severe penalty, for any one to seek to escape after an accident to which his act has contributed.

Relative to good roads or highway improvement, all the Governor has to say to the Legislature in his annual message is this:

Important progress has been made in the construction and improvement of our highways. Of the 520 miles of roads under contract when the new State Highway Commission entered upon its work at the beginning of last year, 201 miles have been completed and accepted, and of the remaining 319 miles, 75 per cent. of the work has been done. In connection with these roads, supplemental agreements were made for construction of 112 miles of bituminous macadam, of which 88 miles have been completed.

During the past year there have been expended for the improvement of county roads $2,847,261, of which the State contributed $1,783,827 and the various counties $1,063,434. Special attention has been paid to repair and maintenance, and $941,000 were expended during the past year upon roads previously completed. Three hundred and seventy-five miles of road have been oiled with a heavy asphalt oil and covered with screenings or gravel.

The total amount available for town highway purposes during the past year, which was expended under the direction of the Commission, was $3,801,732, of which there was raised by highway tax on the towns outside of incorporated villages and cities the sum of $2,436,199, and the State contributed $1,365,533. There was also raised for bridge purposes $747,340.

MASSACHUSETTS LAW IS WORKING SATISFACTORILY

BOSTON, Jan. 31—In his inaugural address, presented to the Legislature recently, Governor Draper, of Massachusetts, says: "The automobile law which was passed by the last Legislature is working well. It is expected that it will produce a net revenue of $175,000 during the next year for use on the State highways; and, with the authority given the Highway Commission to check reckless driving of these vehicles, it is, in the opinion of the commissioners, the most effective automobile law of any State. The Highway Commissioners should be allowed to have sufficient money on hand to enable them to make advances to laborers and others for repair work. Where this work is done at present—there not being money on hand to deal directly with such men—the repairs are unnecessarily expensive. They should also be given authority to buy small sections of land in different parts of the Commonwealth, to be used for the storage of their machinery; and, when opportunity offers, should have the right to purchase land in various sections which furnishes good material for road building. All these purchases of land, either for the storage of machinery or the deposit of material for repairs on roads, should not be completed without the approval of the Governor and Council. I recommend that authority be given the Highway Commission in both these directions, because I feel certain that it will save money for the Commonwealth and permit the commission to render better service."

THE LAW AND THE AUTOMOBILE

TO ILLUME TAXICAB DIALS AT NIGHT

BOSTON, Jan. 31—Managers of the taxicab companies operating in this city are much disturbed by a new rule put out by the State Commissioner of Weights and Measures. Under a law passed last year this official was given power to examine taximeters and see that they were accurate. His first order was that they must be connected with the front and not with the back wheels; then he required that every meter be subjected to a State test as to its accuracy in recording distance and time. These were perfectly satisfactory to the taxicab managers. The latest rule, however, requiring that the dials of the meters be illuminated at night, so that the passenger can more readily tell the charge, is opposed. The managers say that they cannot afford to equip their cabs with dial-illuminating devices and continue to operate them under the taxicab rates. They say that to comply with the rule it will be necessary for them to wire the cabs, install the lights and batteries and also maintain charging stations and a large number of extra batteries. Furthermore, they believe such a rule unnecessary. Two of the smaller taxicab companies have already removed the meters from their cabs, and the larger ones are considering such a step. In case they do, taxicab travel in Boston will be much more expensive than at present, for the other schedule of charges will make the rates much higher for the same distance. The larger taxicab companies equip their drivers with pocket searchlights and require them to illuminate the dial at the end of a trip for the benefit of the passenger. They even keep inspectors on the streets at night to see that this rule is complied with. The manager of one of the large companies states that it will cost from $3,000 to $5,000 a year to comply with the lighting rule, and his company cannot afford to do it under the existing taxicab rates. The taxicab companies probably will take steps to ascertain their exact rights before the law and will combat the enforcement of the rule if they have a fair chance, rather than remove the taximeters from the cabs.

In the end this may work out to an increased rate of fare, since the taxicab company does not exist, which would not welcome the excuse that would allow of doing this very thing. So it is that legislation does not always work out in just the manner expected when it is planned. In so far as the public would really pay for all of the benefits here, it is questionable if it is worth while to make the change as proposed.

ROAD BUILDING NEWS

general tax is levied on the township to reimburse the county.

Under the three-mile law, an election is not necessary. Fifty or more property owners may petition for a road not to exceed three miles in length which will connect an improved road traveled by a rural mail route, at either end. A bond issue and subsequent tax is also provided under this law.

The laws were questioned in a suit brought by Samuel H. Smith against the Hamilton County Commissioners. The general law apparently reads that the township in which the work is to be done must "include" an incorporated city or town of 30,000 or less inhabitants. The court holds that the work may be done in any township in the State, and also in any city or incorporated town of less than 30,000 inhabitants.

Universal demountable rim has many friends among the garage men. Scene in one garage.

GARAGES

The Hokanson Automobile Co., of Madison, Wis., general western Wisconsin representatives for the Buick, Oldsmobile, White steam and gasoline and Oakland cars, on January 26 formally opened its handsome new garage and salesroom building at 14 to 20 East Doty street. The garage is three stories high, with about 30,000 square feet of floor space. The Hokanson company was reorganized several months ago and capitalized at $70,000. Charles F. Spooner is president; Emil Hokanson, vice-president; George P. Miller, treasurer, and Rudolf Hokanson, secretary and manager.

The Baker Motor Vehicle Co. is erecting in Cleveland one of the most modern and completely equipped garages in the United States. The building is 200 by 162 feet, located on Euclid avenue, and built 50 feet back from the street. It will be occupied by the Baker Motor Vehicle Co., Cleveland salesrooms and the Standard Automobile Co., Cleveland distributors of the Packard. The Euclid avenue section will be devoted entirely to show rooms and offices, which will be finished in oak with panelled walls. Two garages, one for gasoline and one for electrics (with repair shops for each), battery department, painting and upholstering shops will be operated in connection. The garages will have a storage capacity of at least 80 electrics and 30 gasoline cars, and will have many new features.

The Taylor Motor Distributing Company, of Philadelphia, has been formed to handle the Warren-Detroit "30" in that city and vicinity. The company includes William P. Taylor, president; Frank B. Cook, vice-president, and Philip M. Price, secretary.

The Bergdoll Motor Car Company, of Philadelphia, has secured the large garage and storage plant formerly occupied by the local. electric bus company, which will be immediately equipped as a factory for building the Bergdoll "30" and Bergdoll taxicabs.

The garage and salesrooms of A. Vernon Hart, Rochester, N. Y., were badly damaged by fire last Friday, and several cars were scorched and otherwise injured. The estimated loss is $10,000. Mr. Hart handles the Thomas Flyer, Oakland and Columbus Electric.

The Garage Equipment Manufacturing Company, of Milwaukee, Wis., manufacturers of motor car accessories, has been incorporated with a capital stock of $100,000. The incorporators are: George F. Discher, D. H. Discher and Theodore Kerner.

W. T. Toops, Harry Ennis and C. H. Smith, of Bowling Green, Ky., have organized the Bowling Green Automobile Company, and will do a garage and supply business as well as handling a line of automobiles.

The Gordon Motor Company, Inc., Richmond, Va., has, on account of increasing business, purchased a large lot on which it will erect a modern garage and salesroom at an estimated cost of $50,000 for the building alone, equipment extra.

The Prothers-McGinnis Auto Company, of Barboo, Wis., has arranged for the erection of a large building during the coming Spring, which will contain its garage as well as a large equipped machine shop.

The Ames Auto Garage Company, of Orrville, Ohio, has been purchased by the Champion Thresher Company. The garage will be enlarged, and R. C. Taylor has been appointed manager

B. H. Smith, of Caro, Mich., is about to erect a one-story building to be used as a garage and repair shop, in which will be handled supplies, sundries and automobile accessories.

In Cleveland, Ohio, Harry S. Moore, agent for the Stoddard-Dayton, will open a garage and salesroom on Euclid avenue, continuing his place of business on Crawford road.

William E. Kennard, in Seneca, Kan., has taken over the automobile garage formerly conducted by Thomas Bennett & Son, and will conduct the business in the future.

The Willis Motor Car Company in Syracuse, N. Y., has taken the Rapid Truck agency for Central New York. James B. Fiedler will manage the truck department.

At Denver, Col., the Studebaker Automobile Company has just moved into the new garage at 1515 Cleveland place. This is a modern two-story building, 50 by 125 feet.

STERN WHEEL TAX ORDINANCE KILLED

The Milwaukee common council committee on judiciary has effectively killed the Stern wheel tax ordinance pending for some time, by recommending indefinite postponement, which has been agreed to by the council. The measure provided for a special tax on all vehicles, including horse-drawn and self-propelled, to raise money for street improvement. The Milwaukee Automobile Club took a decided stand against the measure, and its efforts were successful. The argument of Counsel James T. Drought, of the M. A. C., was that the motor car owners are paying a fair share of taxes in their registration fee and personal property assessments; that the special tax would be double taxation, and that the measure would mean discrimination. This, it was contended was wrong and aside from the original purpose of the bill.

R. C. Hupp, president Hupp Motor Car Company.

AGENCIES

W. H. Wilcox, of Binghamton, N. Y., is handling the well-known Marmon car in the State, excepting for the three or four counties around New York City and some four or five counties in the extreme western end of the State. In addition to the Binghamton district, the Wilcox agency crosses the line into Pennsylvania, taking in two or three counties adjoining. The Wilcox agency reports a brisk demand for this well-known make of automobile, and in the rather rough going in some of the hilly country of New York State, it is claimed that the extremely powerful motors of this make in a chassis which is designed for a low center of gravity and good clearance, users are extremely well pleased and satisfied customers spread the good news everywhere.

The O. G. Roberts Co., Columbus, Ohio, which opened a sales agency and garage at 953 East Gay street a year ago, is planning the erection of a large addition to the plant as soon as the weather will permit. The concern is now the agent for Central Ohio for the Courier, made at Dayton, in addition to the Overland, the Stearns, Jackson, Marion and Stoddard-Dayton.

Rainier motor cars will be represented in Maryland by L. H. Shaab, 116 W. Mount Royal avenue, Baltimore, Md. R. M. Robinson, Albany, has closed the agency for the Rainier in that city and district. Mr. Robinson also represents the Reo and has taken on the Rainier to supply the demand for a high-class car in Central New York.

The Racine Manufacturing Company, of Racine, Wis., is now turning out a large percentage of bodies as before the fire in December. Temporary dry kilns have been erected on the site of the old plant. Every available building in Racine is being used by the company, and new machinery is arriving daily.

The Bejier & Finch Motor Car Co. has been formed at Stevens Point, Wis., to handle the Ford in Portage, Wood and Waupaca counties, Wis. H. J. Finch, of Stevens Point, and Arthur H. Bejier, of Phillips, are the proprietors.

C. A. Woodruff, purchasing agent Chalmers Motor Company.

Among the new branches established along Broadway was noted that of the Gilbert Manufacturing Co., at 2002, next to the corner of Sixty-eighth street, which store will be shared with the Seamless Rubber Co. The Gilbert line of accessories, as well as the Bowers carbureter, will be carried in stock, at all times, the tire accessories being featured.

Tom Botterill Automobile Company, Salt Lake City, Utah, Pierce-Arrow State Agents.

The Sterling car, manufactured in Elkhart, Ind., will be represented in Cleveland by the Sterling Motor Sales Company, a new company, with a capital stock of $30,000, of which J. C. Koepke is manager.

The Hollis-Rand Co., agents for the Speedwell and Pullman cars in Rochester, have opened up temporary quarters in the Triangle Building, that city, which they will occupy until April or May.

The Chalmers-Hipple Co., of Philadelphia, agents for the Chalmers and Hudson, have outgrown their present quarters, and will shortly move to a larger building at 206 North Broad street.

The Obenberger Drop Forge Company has been incorporated at Milwaukee, Wis., with a capital stock of $30,000. John Obenberger, H. W. Ladish and H. C. Fueleuer are the incorporators.

C. M. Logan, formerly with the Cleveland branch of the Olds Motor Works, has secured the agency for Pope-Hartford cars. Mr. Logan's territory includes all of Ohio except Cincinnati.

The Cole "30," according to arrangements just closed, will be handled in Chicago by the Standard Automobile Company. F. C. Bailey is the manager of the local concern.

The Kilpatrick-French Motor Car Company, of Lebanon, Ohio, has been incorporated by J. A. Kilpatrick, A. N. French, Albert French, Howard Ivins and C. Wilbur Ivins.

Ole G. Kinney, of Colfax, Wis., has been appointed agent for the Ford and Brush in the country districts in the vicinity of Colfax and Eau Claire, Wis.

The Ross Motor Company, of Superior, Wis., has secured the local agency for Overland automobiles, in addition to a number of other lines already handled.

The Way-Mitchell-Rigden Company, Cleveland, Ohio, agents for Republic tires and Stromberg carbureters, has secured the agency for Harris oils.

The Pullman Motor Car Company, of Cleveland, Ohio, was incorporated recently with a capital stock of $25,000 by F. C. Thornton and others.

W. L. Hurdle has been appointed agent in Cleveland for the Keystone "6," and will establish headquarters on Euclid avenue, near Sixty-fifth street.

The Ross Motor Co., of Superior, Wis., has been appointed district agent for the Overland, in addition to several other well-known lines.

The Welch car will be distributed in Philadelphia and adjacent territory by Manager Daniels of the Buick branch in that city, according to a recently completed arrangement.

Realm of the Makers

First Abbott-Detroit automobile, designed by John C. Utz. John G. Phillips plays an important part, and A. T. O'Connor is making the sales. The large new plant is producing many cars.

The Cole Motor Car Company entered a "30" at the late Indiana meet, and the after results seems to have proven very conclusively the futility of accepting advanced information in relation to the car ahead or the time taken by any given car. In this case, as it would seem, Endicott, who drove the Cole "30," was told that his time was 19 min. 47 sec. for 20 miles. This record was confirmed, unofficially, the night of the race, and the Henderson Motor Sales Company, which distributes Cole automobiles, wired its branches throughout the country, stating the facts as it believed.

Charles P. Henderson, of the company, having discovered by reading THE AUTOMOBILE that the unofficial time as reported to him was not in accord with the official time, said: "We were amazed when we saw the time published in your journal as 21 min. 22 sec. for 20 miles. We immediately took the matter up with Mr. Warner, who wired us that the time published by your journal was the correct official time for the Cole "30."

Mr. Henderson shows that he believed the first report to be true, and the prompt action which he took, after he read THE AUTOMOBILE and found what was the true time, would seem to make his position perfectly clear.

Hugh N. Harding, the racing driver, who will be remembered as a headliner in drivers of the events of the past six years, has been retained by the Alco, and under the tutorage of B. D. Gray, chief engineer of the company, will undertake important technical investigation for the company. Those who are in a position to know fully appreciate the high technical skill of Mr. Harding—driving with him is a pastime.

Not long ago the Pierce-Arrow Motor Car Company, of Buffalo, began a systematic inquiry with a view to ascertaining the ultimate destiny of all the cars which are made. One result was the bringing out of the remarkable fact that in so far as Pierce-Arrow cars are concerned, substantially 47.5 per cent. of the cars are absorbed by Pierce-Arrow owners. The experts who undertook this investigation expressed the further belief that a man almost always buys a low-priced car at first, and as he gains experience buys one of a higher grade. The tabulation which was made showed that 16.9 per cent. represented the class of people who purchased a car for the first time.

The Royal Tourist is out with a torpedo body which, in addition to being of excellent appearance, has been designed most carefully, according to the reports which emanate from the Tourist engineering office, and H. H. Adams, sales manager from the factory, is kept on the go because of the interest which is taken in this type of car by real buyers. The Chicago office of the Royal Tourist Car Company is 1253 Michigan avenue, where the overflow of the Tourist's friends aggregate when the Tourist booth will hold no more.

The new Torpedo Runabout which is offered in the 1910 Winton product, is attracting considerable favorable comment, which, together with the Winton torpedo type of touring car, completes the advance list, excepting that the really latest idea from this well-known Cleveland plant is embodied in a limousine.

"Report of service by owners of Franklin 1910 automobiles" is a brochure of nice proportions and clean print which is being sent out by the Franklin company, and it tells its own story. It is free for the asking. A little reminder appears on the title page which is very suggestive, i. e., "The man who can best judge the merit of an article is the man who daily uses it."

A Stoddard-Dayton delivery wagon which was built for Fleishman, the florist, Chicago, is attracting notice because of the fanciful art appearance of the body, and the fact that it is giving good service.

The Mitchell Motor Car Company, Racine, Wis., is declining to accept deposits for future deliveries from its agents. James W. Gilson, sales manager of the company, is stout in his defense of this policy, and he points out that if the Mitchell Company was to accept the customary deposit on its output of 6,000 cars the Company would have the use of $300,000 for upwards of a year, for which it would give no adequate return. The Mitchell car, by the way, was one of the sights of the Brussels Show. The consignment to this show comprised a polished chassis, a five-passenger touring car, fully equipped; a seven-passenger machine, and a roadster.

At the big plant of the Nordyke & Marmon Company, Indianapolis, Ind., work is progressing favorably, despite the fact that the deliveries are still well behind orders. In the meantime the company is preparing for its 1910 aggressive racing policy, claiming that racing has had a marked influence on the quality of Marmon cars.

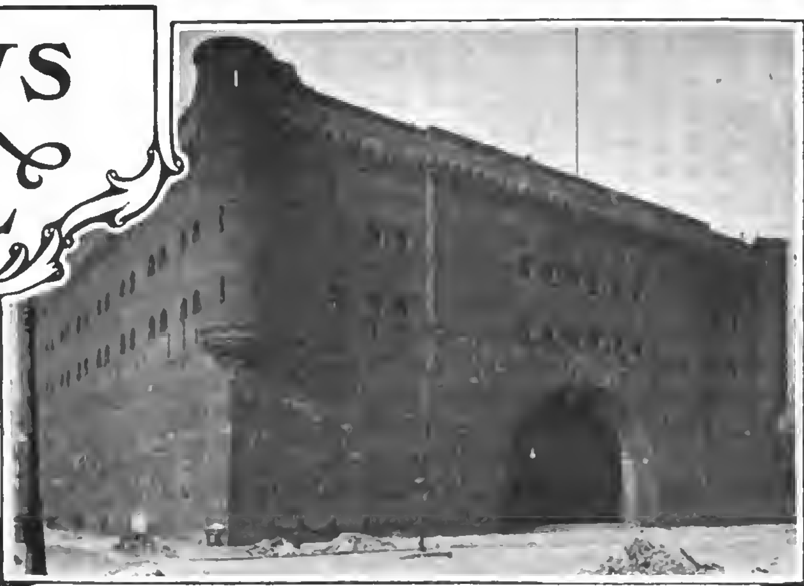
. The Inter-State Automobile Company put out a booklet during the holding of the New York Show entitled, "Why We Named the Inter-State the Bull Dog." It was a neat undertaking, and the demand for the first edition far exceeded the supply. The company has issued a second edition, which is being handed out at Chicago. It is worth sending for, and autoists who are not in a position to visit the show have but to make a direct request to the company at Muncie, Ind., to get a copy.

In the Moon plant at St. Louis, much valuable time is saved through the use of a two-track shipping platform from which two freight cars can be loaded simultaneously. The tracks are so arranged that a big end-door automobile car can be switched close to the platform while a side-door car is already in position on another track.

The Dixie Motor Car Company, of Frederick, Okla., which was recently incorporated for $250,000, is designing an automobile, the price of which will probably be fixed even as low as $1,050. It is the expectation of this company that it will furnish 500 automobiles this year.

Benjamin Briscoe, president and general manager of the Maxwell-Briscoe Motor Company.

News in General



Seventh Regiment Armory, Michigan avenue, where the overflow from the Chicago Show is housed. Connection is through a covered passageway at the back, and along an alleyway eight feet wide.

Chas. Y. Knight has completed a visit to certain of the automobile plants in this country, and left for his English home at "Broadwater," Kenilworth Road, Coventry, Tuesday, February 8, where he will remain for a time sufficient to enable him to complete some motor designs which are projected, after which the Knight motor situation, in connection with the Panhard & Levassor Company, will command his attention. Mr. Knight relates some very interesting phases of the motor situation abroad, and silences the story which has been going the rounds as a side light, to the effect that the Mercedes Company, at Unterturckheim, was running ahead of the original idea and taking out patents which will afford an advantage. It seems that under the terms of the license which is given force between the Knight syndicate and the respective companies, they will not have the right to export automobiles from one to the other country without giving the builders in the relating country full right to adopt and use any special devices which may be found on Knight motors as by them applied.

The Hess-Bright Mfg. Company (H.B.-D.W.F. ball bearings) cordially invites visitors to the Chicago automobile show to call at its recently opened store at 1800 Michigan avenue, where the full line of ball-bearing products of this company are artistically displayed. An accurate and convenient slide rule will be given to each engineer who leaves his name.

In Columbus Director of Safety McCune has issued orders for all violators of the State law to be arrested after February 10, the date set for enforcing the licensing of horse-drawn vehicles.

Herr Hulmle, head of the German ignition firm, U. & H., makers of the U. & H. magneto.

A recent test given the Morgan & Wright Nobby Tread non-skid tire, in Detroit, proved its excellence in the most pronounced way. The test was held on a sharp rise, one studiously avoided by motorists on slippery days. On this occasion the hill was covered with a glare of ice covered with light snow. A Buick car, equipped with these tires, was driven to the foot of the hill, brought to a dead stop, and then started, making the incline without the slightest halt or slip, even under these most unfavorable conditions.

At the second quarterly conference of the branch managers of the Franklin Automobile Co., held in Syracuse, the following representatives were present: W. S. Jewell, New York; A. B. Henley, Boston; George Ostendorf, Buffalo; F. L. Thomas, Chicago; C. H. Rockwell, Cleveland; W. F. Reynolds, Pittsburg; F. H. Sanders, Rochester; J. F. McLean, San Francisco; W. E. Brearley, St. Louis; N. S. Lee, Albany, and George E. Messer, Syracuse. T. R. Lippard and G. D. Babcock, of the Franklin Manufacturing Co., made the opening addresses.

Charles W. Oathout, of New York City, who is Eastern sales manager of the Jackson Automobile Company, is authority for the statement that as far back as 1907 it was proven by a close inspection of the records that $70,000,000 was spent yearly in the upkeep of 49,000 automobiles, which he states were then in operation in the State of New York alone. According to the same authority, this repair account mounted up to nearly $90,000,000 in 1908, and $7,000,000 more must be added to cover the increase for 1909.

The National Sales Corporation has issued for the trade a combination electrotype sheet of their automobile accessories. This pamphlet is so arranged that the descriptions may be cut out and pasted into the dummy of any catalogue.

Strict orders have been issued to the police departments of Dayton and Cincinnati to enforce the State automobile law after February 1. It is reported that many owners are operating cars without the 1910 number plates, and after the first of the month all will be arrested and prosecuted.

The B. F. Goodrich Company, of Akron, Ohio, at its annual stockholders' meeting, approved plans for extensive additions and betterments to the plant. While no direct statement was made, it was intimated that about $1,000,000 will be spent during the coming year. The meeting marked the retirement of Walter A. Folger, treasurer of the corporation. He was succeeded by W. A. Means, who has been assistant treasurer. Secretary C. B. Raymond was elected to the additional office of assistant treasurer. The other officers are: B. G. Work, president; F. H. Mason, first vice-president; H. E. Raymond, second vice-president, and E. C. Shaw, general manager.

The Mitchell-Lewis Motor Co., of Racine, Wis., the new $10,000,000 corporation at Racine, Wis., has established a large dining-room in the new general office building, where employes may obtain meals at cost.

At this early date Pennsylvania registrations have reached the 10,000 mark for the year 1910. The majority of cars registered are above twenty horse power. It is expected that the total for the year will aggregate between 35,000 and 40,000 registrations.

CHANGE OF NAME—YORK MOTOR CAR CO.

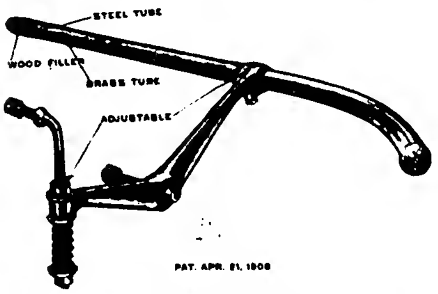
In accordance with its progressive policy, and also due to the fact that the company has outgrown its local name, the York Motor Car Company, of York, Pa., recently applied to the courts for a change of name, which has been granted, and, commencing Feb. 1, 1910, the company will be known as the Pullman Motor Car Company, Inc.

The demand for Pullman automobiles has grown so rapidly that the company is very much behind in its orders, but with the completion of an additional plant at Evansville, Ind., in the early summer, the output will be greatly increased, and the company will be prepared for this demand.

The officers and personnel of the new company remain unchanged. The change, as previously stated, is made so as to harmonize more with the character of its output, and to avoid the confusion which would necessarily result after the establishment of the plant at Evansville, Ind.

Prominent Accessories

The Sager Bumper—The construction of a bumper capable of protecting the lamps and radiator of a heavy automobile running at high speed is not such an easy matter as one might casually suppose. The bumper in question, although it is not claimed that it will protect the car from damage in the event of its running into a stone wall at sixty miles an hour, is nevertheless substantial enough to afford a very material protection to those delicate parts



Sager's new bumper construction, showing adjustment at front end.

of the automobile which of necessity, it seems, must always be placed at its front end.

The cross bar, which receives most of the hard knocks in service, is a triple construction of an unusual and meritorious sort. The body of the bar is a stout steel tube; this is reinforced by a round bar of wood driven solidly into place. The whole is then, for appearance sake, driven into a second tube of brass. The cross bar thus formed has remarkable strength, and at the same time keeps its appearance well, not being easily bent or dented.

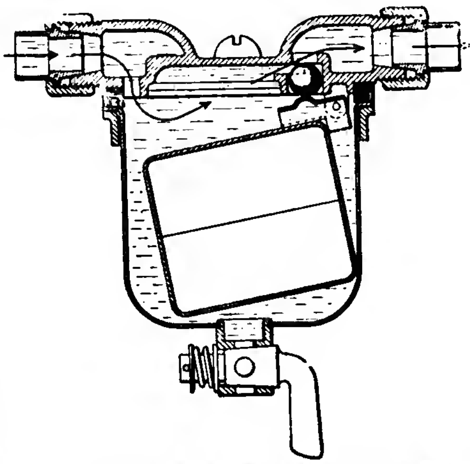
Considerable stress is laid on the construction of this bar, because it is quite important for the popularity of the device that it should retain its good looks. Accidents in which the bumper is involved are by no means necessarily the fault of the owner of the car, and he naturally does not like to have it look battered and worn.

The bar is supported on two brackets cast of manganese bronze, of I-section. These are provided with steel pivot bolts, and at their rear ends are cushioned by steel coil springs. The springs are of steel rods which pass through eyes in the ends of the brackets, being held between the brackets and nuts on the ends of the rods, so that they are in compression whenever the bumper bar is forced back. Stop-nuts are provided above the brackets, by means of which the position of the bumper bar can be regulated. The firm of J. H. Sager & Co., of Rochester, N. Y., which also makes the Sager spring shock absorbers, is marketing this improved bumper.

H. W. Nuckols, General Manager Columbia Motor Car Company.

"No-Shammy" Gasoline Strainer—Gasoline strainers usually will not separate any more water than they can hold, which at best is but two or three teaspoonsful; when water still continues to come to the trap it passes through as easily as the gasoline, and enters the carbureter. The feature of the "No-Shammy" strainer is that it automatically closes when water beyond its capacity reaches it, and so prevents any water getting into the pipe between the strainer and the carbureter.

The strainer contains a float, which is so adjusted as to sink in gasoline, but float in water. As long as nothing but gasoline passes through, the float is inoperative; but when the strainer pocket gets full of water the float rises and cuts off the feed of gasoline. This, of course, stops the motor, and so calls the driver's attention. After the water has been let out at the petcock, the float valve opens



No-Shammy strainer has a float like a carbureter, and convenient drain cock.

and admits pure gasoline to the carbureter. The motor will then start on the first turn of the crank.

The "No-Shammy" strainer is made to fit all sizes of piping, from 3-16 to 1-2 inches* outside diameter. It has been adopted as regular on six 1910 cars.

Hart Gas Lamp Ignitor—This device is unique among similar ones in that it makes use of the regular high-tension ignition system of the car to effect the lighting of the headlights, instead of providing a coil of its own. It is connected with one of the coil units or with one terminal of the magneto, according to conditions. The use of the ignitor thus sidetracks the current from one cylinder momentarily; turning the switch to light the lamps causes one or two misses of the cylinder which should have received the "juice," but as a single spark does the work on the headlight the skip is hardly perceptible.

The ignitor can be applied to any car in a few minutes. One cable leads to each light, the return being grounded. A three-pole switch is provided for the dash by which it is operated. The sparking points which are applied to the acetylene jet are exactly the same in principle as a spark plug. As they spark in the open air, instead of under compression, when their switch is on and the high-tension current is given its choice of the spark-plug route or the ignitor, it takes the ignitor every time. As the device needs no batteries or other source of current distinct from that of the regular ignition system, and likewise needs no separate coil, the maker, H. T. Hart, of Hartford, Conn., is enabled to sell it at a low price.

The Wohlfeld Tire Trunk—To redeem the space within the spare tires usually carried on a tour it has become quite general to provide a circular trunk to fit inside of them. With the large tires which are coming into general use, the space available for such trunks has increased, until now a considerable amount of luggage can safely be carried in that way. The only objection urged against these trunks has been that all were not as strictly waterproof as might be desired.

With the view of making such a trunk which would be waterproof in the most severe storm, S. Wohlfeld & Company, of Philadelphia, got out an entirely new idea in the way of providing the necessary opening. The outer end of this trunk is, as usual, divided horizontally across the middle; but instead of being hinged on this dividing line, the upper and lower parts are joined by a single central pivot. This allows the upper half to slide down over the lower half to open the trunk. The waterproof feature is accomplished by having the upper half overlap the lower considerably when in the closed position, and at the same time the cylindrical body of the trunk has a lip which overlaps the edge of the upper section. Substantial locks are provided, and it is claimed that the trunk is absolutely water and dust-proof.

Wohlfeld waterproof tire trunk shown closed, with solid and reliable locks.

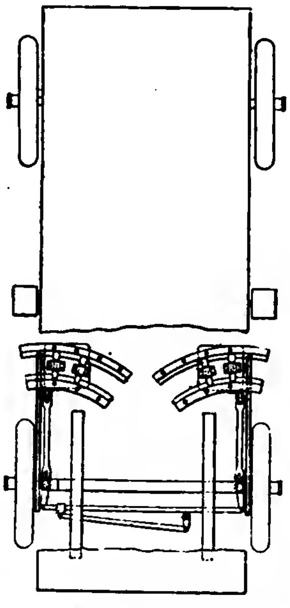
PATENTS AND PROCESSES

INVENTIONS and inventors have always had a peculiar fascination for American people, whether due to a natural inventive genius inherent in all of us, or to a receptive attitude towards things new, better and different, is hard to say. Nevertheless, tbis feeling exists, and in no small degree, either. To care for this, in part at least, THE AUTOMOBILE proposes to set aside one page each week for matter relative to both inventions and inventors. It will be the idea to bave a competent authority deal with these subjects, so that the matter may present something of worth and the space not be wasted.

For the present week the portrait of Thomas A. Edison is presented. Mr. Edison is without a doubt one of America's foremost inventors, in which chosen field he has shown a touch of rare versatility, his inventions being of many kinds, touching as they have things electrical, mechanical, chemical, electrochemical, and pertaining to other branches of science.

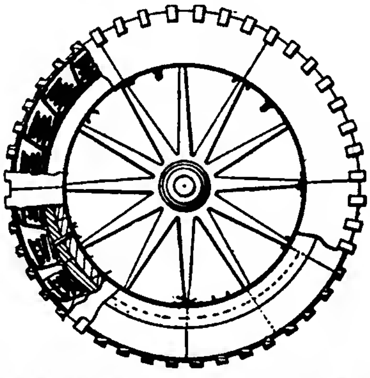
While not the purpose to expand upon any one man's inventions, and thus exploit him, as it were, it will serve as complete proof of the man's ability as an inventor to mention his work in storage batteries, his phonograph, his magnetic low-grade iron ore separator, his more recent work in connection with photography, and in particular with moving pictures, to say nothing of his work in cement, including as it does an attempt to construct a complete house at a price within the means of every working man, which house will have all of the many advantages of concrete construction.

From the latest information, it would appear as if he has now turned to automobile construction, probably drawn thereto by his work in this connection on storage batteries. As shown by the latest patent office gazette, namely, the issue of February 1, a patent has been granted him on what appears to be a development of the forecarriage idea. This is to drive the front wheels, utilizing tbem for steering as well. In this way tbe whole power and transmission unit becomes one unit, which is readily removable as a whole. In the present invention, illustrated elsewhere on this page, no mention is made of the motive power, the claim speaking broadly of a motor. The latter is mounted upon a forward truck, in such a manner as to turn with it. A further proviso is made of radial ways or tracks upon which the weight of the motor may be supported during the turning process. Although worked out in somewhat different form, this same construction was used abroad in the Italian forecarriage, Cantano, and has been very successful. This, by way of passing mention, was electrically driven from storage batteries.



Edison's fore-carriage system, using the front wheels for driving and steering.

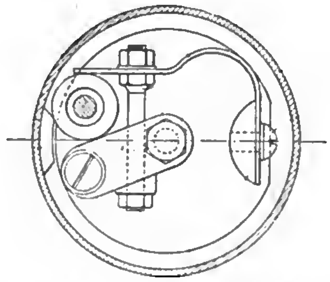
Like the non-refillable bottle, the spring wheel is a sort of hardy perennial, a new inventor with a brand-new solution of the tire problem, worked out as a spring wheel, cropping up every little while. This is not said in a sense of disparagement, but rather as comment upon the number and variety of the spring wheel inventions. In the latest gazette a patent is described whicb has just been granted to Rudolph J. Lackner, of New York City, the exact official designation being a spring tire. In this tire Mr. Lackner utilizes the usual felloe, upon which a series of small coil springs are mounted. At their outer ends these springs carry rubber caps, while tongues are interposed between the springs and connected at the inner ends to the felloe, have their outer ends angularly disposed, and so arranged as to press inwardly against the ends of the rubber caps. This forms a combination of wheel and tire which has, among many other virtues, that of the rubber caps being readily removed for inspection, adjustment or repair.



Spring wheel patented by Rudolph Lackner, using a multiplicity of coil springs.

Probably no one distinct part of the automobile has excited more attention at the hands of inventors in the past two years than the ignition system and its many details. As exemplifying one of the well-worked-out smaller details, the third patent reproduced this week is that of a German magneto man, Hermann Ruthardt, of Stuttgart. This gentleman is the inventor and manufacturer of the Ruthardt magneto, to which the Herz (American) magneto bears some resemblance. Herr Ruthardt's invention, as described in the gazette, is a rotary current-breaker. This breaker is equipped with a spring on unusual and noticeable shape, this being comparable to a combination of two letter U's, one inverted and the other flattened out. On this flat part is carried the platinum point, which is of unusual size. The outer end of the flattened part is the portion upon which the circular but eccentric cam operates to cause the break. The housing forms a sort of circular box, which is rotated bodily to advance or retard the time of the spark.

At least one prominent automobile company is represented in the gazette as assignee, that one being the American Locomotive Company, to which Budd D. Gray assigns his patent on the rear axle construction now used on the Alco cars. The specifications call for a central annular body adapted for the reception of driving mechanism, tubular supporting members continuous with and oppositely projecting from said central body, a spacer fixed in the central body, and tubular liners fixed in the tubular supporting members and abutting at their inner ends against the spacer.



Circuit-breaker for magneto use, embodying a number of refinements of merit.

Further claims cover the method of securing the tubular liners, intended to carry the wheel bearings of the full floating axle. in the projecting supports on the central body. One method is to shrink a band over the end of the supporting tube, thereby clamping it against the tubular liner.

Still another claim is for a construction in which the spacer and the axle tubes are assembled first, and then covered by a central body made of pressed steel in two halves, the halves being then welded together, uniting this body with the tubes.

This axle construction seems one of the neatest at present in use. It was originated for the Alco taxicab and light town car, but its success was such that this year it is to be used exclusively on all the models of this company, including the four-cylinder 40-horsepower and the six-cylinder 60-horsepower, which formerly had chain drive.

Thomas Alva Edison, who has turned to automobile improvements recently.

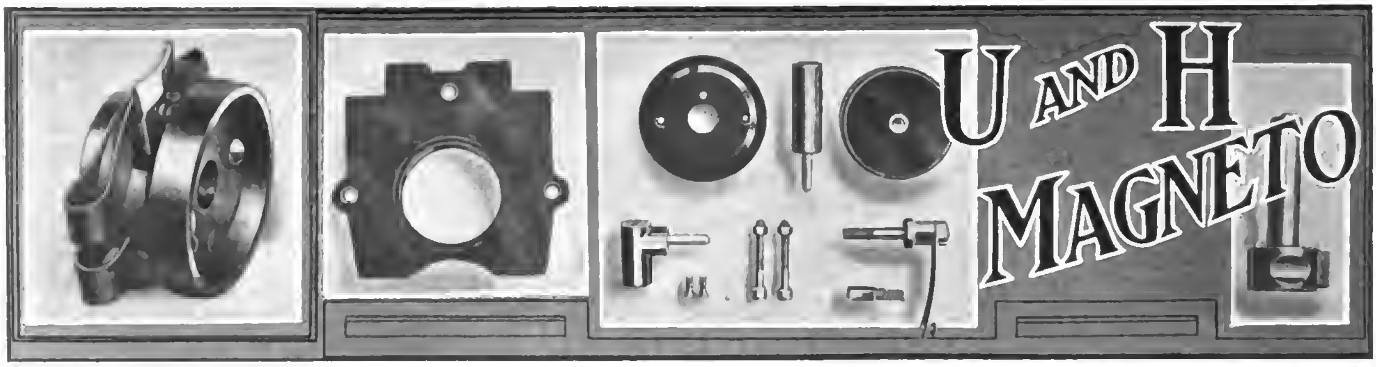


Fig. 1—Parts of magnetos, which are made to standard, in order that the rapid supply of repairs will be facilitated

THIS magneto has a double winding on its armature and is of the true high-tension type. It is made in the several styles as required in ignition work, has been before the automobile public for several years, and has earned a reputation for uniform stability. The product is made by Unterberg & Helmle, Durlach, Germany, and is distributed in the United States by J. S. Bretz Company, New York City.

Of the several types of U & H magnetos which are made, reference will be here made to two; they being enough to support the points which it is the desire to make. Fig. 1 (the title illustration) shows something of the work of standardization; parts are kept in stock at all branches of the maker, in quantity sufficient to satisfy every emergency. The part on the left, in Fig. 1, is the interrupter, which is common to all the types of this company, and, considering the great importance of this particular part in a magneto, it is well to examine it closely with a view to noting its ability.

The interrupter comprises a bronze barrel to one end of which is riveted a steel centering disc. This disc is recessed, and fits over a corresponding projection on the condenser casing, thereby locating the interrupter in true concentric relation when it is mounted into position; skill is not necessary in the process. In assembling, the flexible phosphor bronze member is interposed, and the success of the interrupter is due to this shape.

PROPER SPEED OF ROTATION OF U & H MAGNETOS

The speed of rotation of a magneto of this character bears a definite relation to the speed of rotation of the crankshaft of the motor, and to the number of cylinders of the motor, assuming that there is one spark plug in each cylinder of the motor—referring, of course, to four-cycle types of motors. For the several motors the speeds should be as follows:

Considering 4-Cycle Work

(A) 3-cylinder motors—the magneto armature must be run at 3-4 of crankshaft speed.

(B) 4-cylinder motors—the magneto armature must run at the crankshaft speed.

(C) 6-cylinder motors—the magneto armature must run at 1 1-2 times the crankshaft speed.

(D) 8-cylinder motors—the magneto armature must run at double the crankshaft speed.

Considering 2-Cycle Motors

(E) 2-cylinder motors—the magneto must run at the speed of the crankshaft.

(F) 3-cylinder motors—the magneto must run at 1 1-2 times the crankshaft speed.

(G) 4-cylinder motors—the magento must run at double the crankshaft speed.

The direction of rotation of the magneto armature is fixed when the magnetos are assembled in the shop of the maker. A small arrow printed in the metal at the driving spindle end, shows the intended direction of rotation, but by altering the relative position of the interrupter the direction of rotation will be reversed, considering the proper working of the magneto—no mechanical damage will follow if the magneto armature is rotated in either direction; the only point to be remembered is that the spark will not be properly timed unless the connections are properly made for the right direction of rotation.

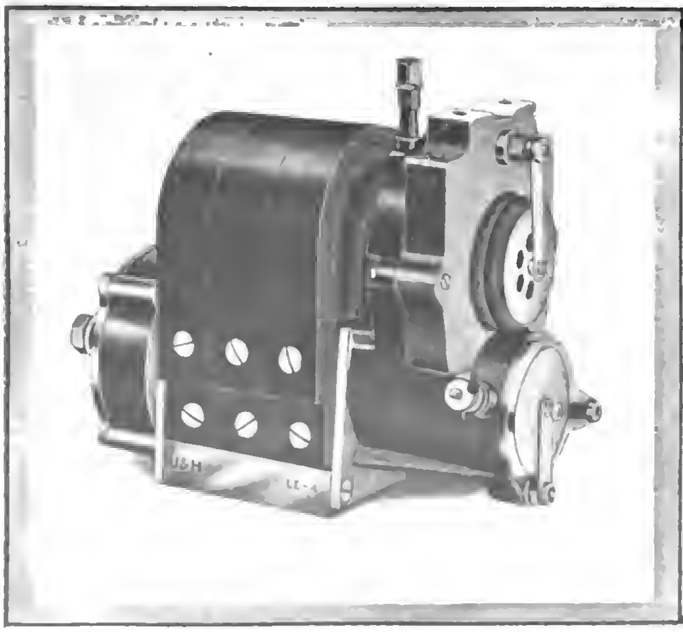

Fig. 2—Type L E 4 magneto, which is made for motors up to eight cylinders, and with a device for starting from the seat

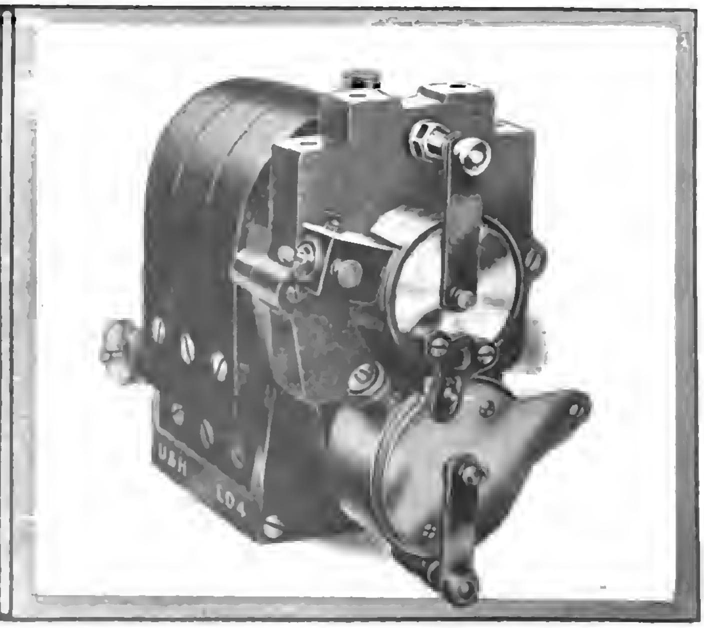

Fig. 3—Type L D 4 magneto, as made for any number of cylinders up to eight, is also intended for dual work

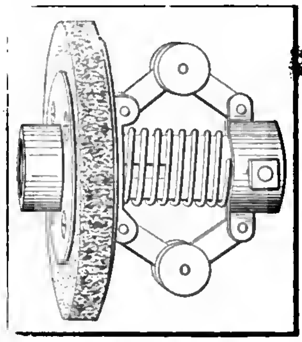
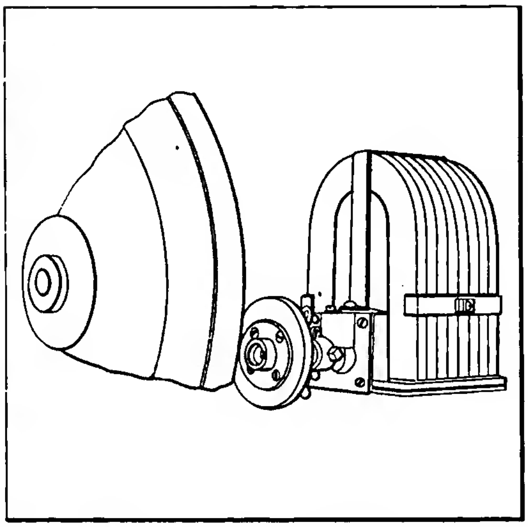
THE HOLTZER-CABOT IGNITION SYSTEM





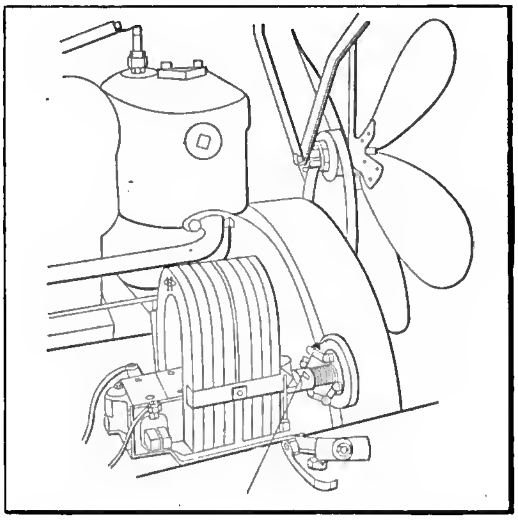


Fig. 1—Presenting details of end friction governor. Fig. 2—Showing method of applying end friction governor. Fig. 3—Type J. S. magneto, as attached to a Stevens-Duryea car.

IGNITION devices, as made by this company, are so contrived that, by means of a pulley drive, the magneto, in any given application, may be quickly and cheaply made to fit any existing automobile, thus doing away with the battery, or reducing it to a position of secondary importance. Many autoists, having failed to keep the battery system up to an efficient state, or, preferring to make a greater initial investment in the interest of diminished attention later on, employ this system. From the point of view of the makers of automobiles, it is equally available, and, in view of its ease of application coupled with a certain reliability, it is being taken up and used to an extent which is particularly noticeable.

With a view to presenting the system in its most simple form, advantage is taken of illustrations, in which Fig. 1 is of the J. S. type of magneto, as it was applied to a Stevens-Duryea car; Fig. 2 is an application of the magneto using a friction governor, and Fig. 3 shows the details of a governor, of which the maker has several designs, each one of which has a place in this class of work. Fig. 4 depicts the method of wiring which will afford the desired result considering a 4-cylinder, 4-cycle motor, and Fig. 5 presents the method of wiring when a jack-knife switch is interposed for the purpose of changing the polarity of the current, which is advantageous.

It is the claim of the maker that cork is the best material to use as the friction member in the pulley system, and this material is adapted as the standard. Fig. 2, which is the end-friction governor, is designed to keep the speed of the armature constant so that the voltage of the armature is substantially constant, although the speed of the crankshaft of the motor may change, as it does in service, over broad ranges. Besides this end-friction governor, there is a bevel type, and what is known as the "standard" type as well. The standard type of friction governor is provided with a flat-faced pulley, and contacts with the face of the flywheel of the motor. The proportion, that is to say, the diameter of the friction pulley as it relates to the diameter of the flywheel, must be considered in making an application, and, if the motor speed is a variable, as it is in automobile work, this fact must be taken into account. In ordering, if the purchaser will give the desired data, the maker will fix all the dimensions, and when the magneto is then placed, it will work without further adjustment.

FACTS IN RELATION TO THE DESIGN OF THE MAGNETO

The permanent magnets are of circular section, made of a special grade of magnet steel in which retentivity is realized to a maximum, and the strength of the magnetic field is high enough to assure the desired result. The armature is of the slotted type; windings are imbedded, and insulation is adequate for every emergency—the insulation is thoroughly protected by the slots. The armature spindle is of relatively great rigidity; it is 1-2-inch in diameter, and the bearings, which are of phosphor bronze, are allowed a sufficient projected area to last for a sufficiently long period of time to eliminate trouble from this quarter to a noticeable degree.

Lubrication is by means of a grease cup, involving the application of a steel ball which rides on the shaft and pinches off the supply of lubricant by resting on the seat of the cup. A dual system of brushes, which represent an unusual feature in magneto work, assures that at least one set of brushes will be in good electrical contact, unless it transpires that the care given the magneto takes on a characteristic which may better go by the name of positive and long-continued neglect.

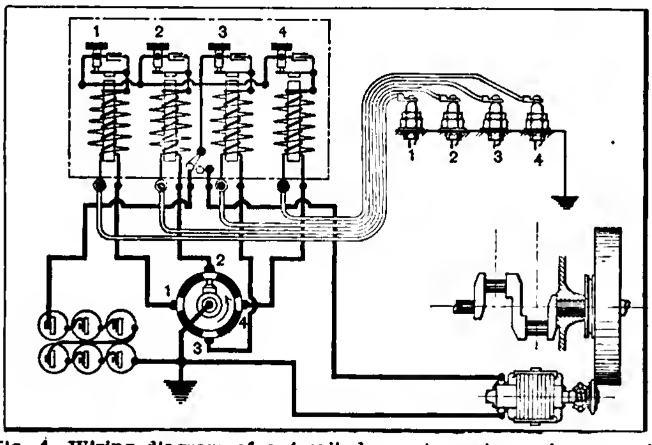

Fig. 4—Wiring diagram of a 4-cylinder motor using a jump-spark system

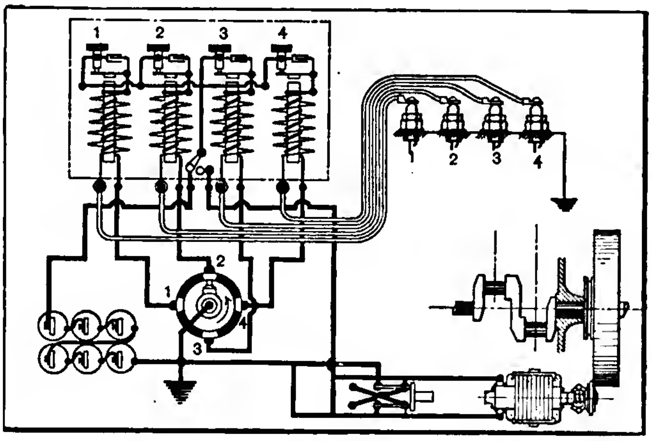

Fig. 5—Four-cylinder wiring diagram, with a polarity-changing switch

1910 COMMERCIAL

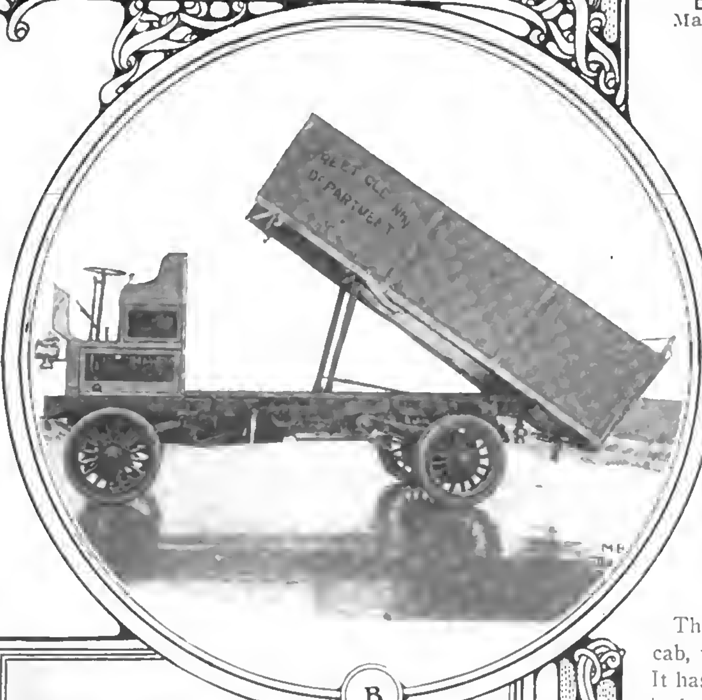
D

A—Hewitt Motor Company's 2-ton delivery wagon, used by Colgate & Company in the delivery of soap.

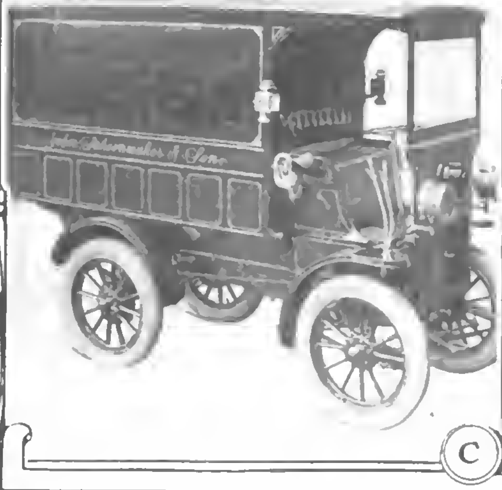
B—A Manhattan truck fitted out with a tilting body of steel, for use in the Street Cleaning Department. The body is shown tilted to the dumping position.

C—Franklin delivery wagon as used in Newburgh, N. Y., by John Schoonmaker & Son.

D—A big truck made by R. L. Morgan Company, of Worcester, Mass., with a load of cement in bags.



B



C

COMMERCIALS, as they are exhibited at Chicago, include eight forms of strictly business wagons and one taxicab, the latter being a Thomas. The commercial situation is better represented in the tables as published in THE AUTOMOBILE, issue of February 3, which includes 45 makes, including taxicabs. This branch of the automobile industry is rapidly assuming the importance it is entitled to, and it is predicted by those who have followed the commercial situation closely that it is now but a matter of little further experience on the part of users when they will be convinced of the desirability of utilizing commercial vehicles to the entire exclusion of animal-drawn wagons.' A few of the types of cars which are now in common use in commercial pursuits are here illustrated, they having been taken at random with the expectation of showing to what extent the commercial situation is spreading out, rather than to confine them to just the types of power wagons which are on parade at the show.

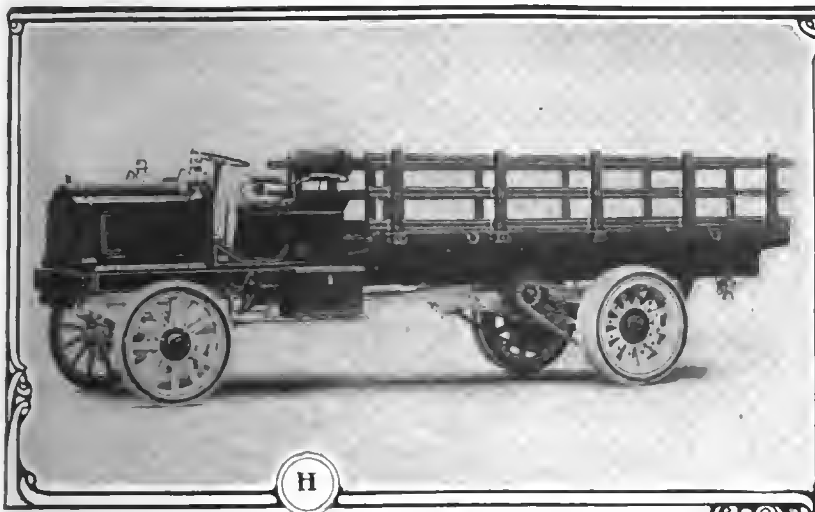
AMERICAN LOCOMOTIVE CO. PRESENTS THE ALCO

The Alco, in a commercial sense, is available as a model 16 taxicab, with a 24.8-horsepower motor, taking the A. L. A. M. rating. It has four cylinders, 100 by 120 millimeters bore and stroke, respectively, with a cellular type radiator, centrifugal water pump, Bosch magneto without auxiliaries, four-feed lubricating system, multiple disc clutch and three-speed selective transmission gear with reverse. The wheel base is 104 inches, with a 55 1-8-inch tread. Bearings are anti-frietion, excepting in crankshaft, and the tires are all 32 by 4.

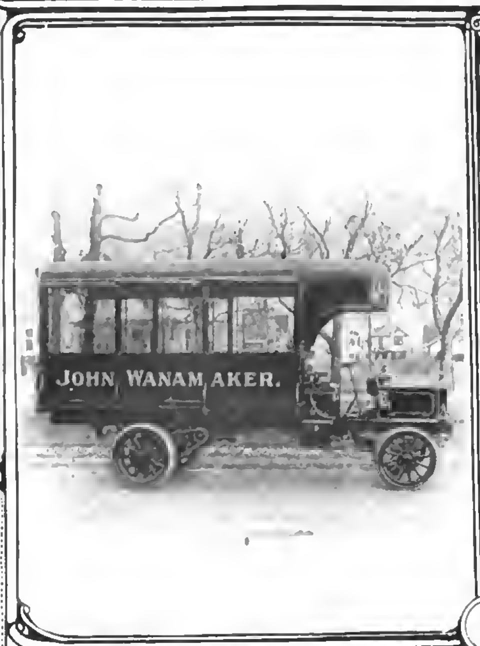
The Alco truck, which sells at $3,500, has the same size motor as in the taxicab, and the same motor details obtain throughout. The wheelbase is 110 inches, and it has a side-chain drive, whereas the taxicab has a shaft drive. The tires on the truck are 36 by 5 inches in front and dual 36 by 3 1-2 inches in the rear.

FRANKLIN OFFERS THREE TYPES OF COMMERCIALS THIS YEAR

This line includes Models L-1, L-2 and J-3. Each of these models is provided with the same size motor, which is four-cylinder, air-cooled, with a bore of 3 3-8 inches, and a stroke of 4 inches. The ignition is by Bosch magneto without auxiliary. The mechanical lubricator has four feeds; the multiple dise clutch works in conjunction with a three-speed transmission system, and the wheelbase is 83 inches for Models L-1 and L-2 and 100 inches for Model J-3. These cars weigh 1,750 pounds for Model L-1, 1,850 pounds for



H



E

E—Packard truck with a furniture body in the service of John Wanamaker.

F—Alco 3-ton truck with a 4-cylinder 24-horsepower motor, with a large and commodious platform.

G—Grabowsky truck with a double-opposed motor unit design, located in front, used for delivery by the New York "World" on hilly Staten Island.

H—Packard 3-ton truck with standard body, presenting a long platform, and ample room.

F

G

Model L-2 and 2,550 pounds for Model J-3. In view of the power supplied and the load carried, the weight is low.

GRABOWSKY HAS DEMOUNTABLE POWER PLANT

Grabowsky offers four models, but the motor is identical in three of them, namely: 101-A, 313-A and 505-A. This motor is a double-opposed type with a bore of 5 1-2 inches and a stroke of 5 inches. In the Model 507-A the bore is increased to 6 inches, but the stroke remains at 5 inches. The motor is mounted in front on a subframe, and is so contrived with its accessories in a self-contained relation that when the motor is unbolted the entire power plant may be shifted out to the front without disturbing the radiator, which latter equipment is located above and to the rear of the power plant. The radiators used are of the tubular type, but they differ from other radiators in that a steam compartment is introduced above the water level.

KNOX OFFERS A CAR FOR EVERY COMMERCIAL PURPOSE

The Knox line comprises seven distinct models, ranging in price from $1,400 to $4,300; the lightest model has a single-cylinder, 10-horsepower motor and the largest is provided with a four-cylinder motor with a rating of 48.4-horsepower A. L. A. M. This particular motor has a bore and stroke of 5 1-2 inches. Cylinders are individual; a cellular radiator in conjunction with a centrifugal pump provides for cooling, and a Bosch magneto in conjunction with a coil and storage battery is used in the ignition system. The lightest truck weighs 1,800 pounds, and the several sizes range in weight to the largest one which tips the beam at 5,600.

PACKARD IS PROVIDING LIBERALLY FOR TRUCK WORK

The best indication of Packard progress in the commercial line is that as represented by the large new plant, which is completed and being fitted out exclusively for the building of trucks. These trucks were especially designed, entirely disregarding Packard pleasure vehicles, and are intended to undertake the most severe service, on a basis of economy of maintenance, rather than to attempt to fix a low purchase price.

The Rapid line has four models, ranging from 20 to 48-horsepower A. L. A. M. rating; two of the models employ a double-opposed motor, and the two heavier trucks have four-cylinder motors, all being water-cooled. Tubular radiators and centrifugal pumps obtain, and ignition is by coil and storage battery.

LATEST KNIGHT DEVELOPMENTS

SILENCE commends itself, at least in automobile construction, and the combination of silence with increased efficiency is one that every automobile designer in the country is striving to obtain. The attainment of this combination, to a very considerable degree, is the claim of the Knight motor, and that the claim is justified, a year's service of stock models in the hands of ordinary purchasers has amply proved.

The first public appearance of the Knight slide valve was at the Chicago show of 1906, where a car was exhibited by Knight & Kilbourne. This car was illustrated and described in THE AUTOMOBILE, February 15, 1906. Quite a little comment was excited, by no means all of it favorable, and it is not believed that the actual sales were sufficient to increase noticeably the manufacturer's bank account. Like many another novelty, interesting for the moment, the Knight motor had almost been forgotten when in the early part of 1908 announcement was made that it had been adopted by the Daimler Motor Company, of Coventry, England, one of the oldest and supposed to be one of the most conservative of British manufacturers.

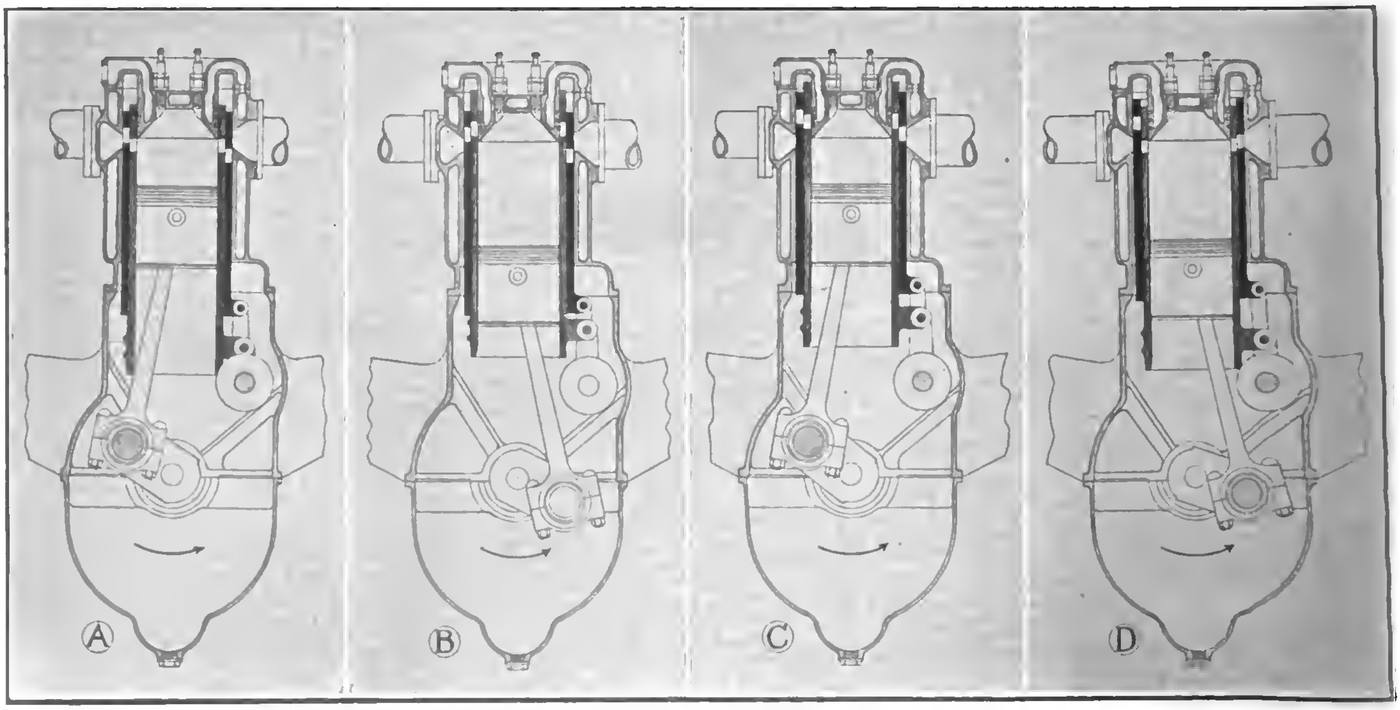
True to its word, the Daimler Company used the Knight valve system on all of its 1909 product, and these cars are in use with great success, both in England and on the Continent. Further, the Minerva Motor Company, of Antwerp, Belgium; Panhard & Levassor, of Paris, France; the Daimler Motoren Gesellschaft, of Untertuerckheim, Germany, which makes the Mercedes, and the Deluca Daimler Company, of Naples, Italy, have all received from Mr. Knight permission to use his valve system, and it is a matter of positive knowledge that four prominent American makers are experimenting with it, one having six cars so equipped actually on the road.

Most people interested in automobile design know that the Knight valve system consists of two concentric sleeves or liners in each cylinder, which move up and down and thereby open or close ports in the cylinder walls which act as inlet and exhaust valves. The exact operation of these sleeves, however, has been more or less a mystery. This is not unnatural, for the movements are much more complex than those of an ordinary poppet valve system. With this in view, the Daimler Company has had made and sells at one shilling sixpence an ingenious cardboard working model of the Daimler-Knignt motor. Drawings from this model in four typical positions are shown herewith.

The inlet and exhaust ports in the cylinder wall are diametrically opposite. Each sleeve has in it two slots, one for the inlet and one for the exhaust. It is obvious that to secure the valve opening the slots in the two sleeves must simultaneously register with each other and with the port in the cylinder wall. The inlet and exhaust slots in the inner sleeve are on the same level; on the outer sleeve the inlet slot is considerably above the exhaust slot. The sleeves are moved up and down by eccentrics on a shaft corresponding to the camshaft of an ordinary motor.

The crucial point is the timing of these eccentrics, and the corresponding movements imparted to the sleeves with respect to each other and to the cylinder. The inner sleeve reaches its highest point at the beginning of the expansion stroke, and its lowest point consequently at the end of the exhaust stroke and the beginning of the inlet stroke. The outer sleeve, on the other hand, is about half a revolution away from the inner one; it reaches its highest point at the end of the expansion stroke and its lowest at the end of the suction stroke. At the highest point in the travel of the outer sleeve its exhaust slot is approximately in registry with the exhaust port of the cylinder, and at its lowest point registers with the inlet port. The inner sleeve, on the contrary, has both of its slots in registry with their ports when it is at the bottom of its stroke.

It is now possible intelligently to follow the motor througb an entire cycle. Beginning with the inlet stroke, the inner sleeve has its port in line, and the opening is affected by the downward movement of the outer sleeve, bringing its slot into line. Then both sleeves move upward together at the end of this stroke. This upward movement leaves the exhaust slot of the outer sleeve in line with the exhaust port. During the expansion stroke the inner sleeve is moving downward, and the exhaust opening is effected when its slot comes into registry with the other two. Then, while the inner sleeve stands still, the outer sleeve begins a downward movement which results in the



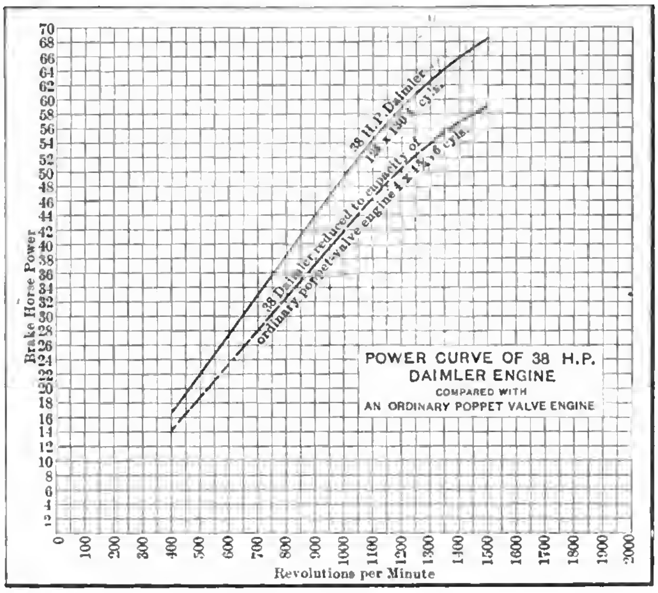
Section Through Knight Motor, Showing at A Inlet, at B Compression, at C Firing, and at D Exhaust

closing of the exhaust port and the opening of the inlet.

The most enthusiastic advocates of the Knight system do not claim that it is simpler than the poppet valve mechanism. To the two poppet valves in each cylinder correspond the two sleeves; these must be ground with the utmost accuracy on both the inner and outer walls. The camshaft is replaced by the eccentric shaft, and the valve tappets by the connecting rods between the eccentrics and the sleeves which they actuate. Springs, however, are dispensed with. In addition, the Knight motor cylinder must have a removable head fitted with three additional packing rings, to keep tight the joint between the head and the inner sleeve.

First of the objections offered against this construction is the difficulty of lubricating the sliding sleeves. This difficulty on the face of it seems considerable; yet the best evidence possible to quote in proof that it has been overcome is the successful use of stock cars for a year and more. Although it is not known just what provision the Daimler Company has made in this respect, at least one of the American concerns at present experimenting with the motor has worked out a scheme whereby the cylinder lubricating oil is forced to pass between the sleeves on its way to the piston. It should be remembered that the speed of the sleeves is only about one-fifth that of the piston, and that no thrust is exerted on them by the explosion save that resulting from the angularity of the connecting rod. This is one of the principal differences between the Knight system and other kinds of slide valves and rotary valves, in which any pressure in the cylinder means an equal lateral pressure of the valve against its seat.

In the size of its valve openings the Knight motor is superior to those using poppets. It is customary to speak of a poppet valve as being so many inches in diameter, and to an untechnical mind a poppet valve two inches in diameter has little to distinguished it from an open hole of the same diameter. Actually a poppet valve offers but a narrow slit or opening, and when the valve is in a pocket this slit is effective only on the side nearest the cylinder bore. On the Knight motor the slit is of double or triple the width, and directly in the cylinder wall.



Power Curve of 38-Horsepower Knight Engine

Indicator curves taken from Knight motors show a very perfect expansion line; the increase of pressure following ignition is not sudden or excessive, and the pressure falls off with more regularity and uniformity than in poppet-valve motors. The mean effective pressure is claimed to be in the neighborhood of 100 pounds to the square inch, as against say 70 pounds for the ordinary motor. Although it is difficult to assign a wordy reason, the fact remains. Further, the Knight motors show a far more uniform relation of power and speed than usual. Their power curves are practically straight lines, and it has often been found impossible to reach the peak of the curve in tests, without serious danger of injury to the mechanical components of the motor. No better demonstration could be asked of the efficiency of the valves, considered as a method of transferring gases.

FOREIGN CARS STILL HOLD THEIR AMERICAN MARKET

ALTHOUGH the foreign cars sold in this country no longer maintain their former position of haughty superiority, American designers cannot suppose that there is nothing to be learned from the invaders. In details of construction which reveal thought and experience, as well as in more prominent features, the foreign cars which have been exhibited at the various shows have much that is of interest.

In the domain of light town cars Fiat is building a chassis of 12 horsepower, nominal, which for this purpose could hardly be surpassed. The motor has four cylinders 80 by 100 millimeters (3.15 by 3.94 inches), cast in a block, with all valves on the left side. The hood is very short, so that with a wheelbase of 107 inches there is ample room for an extension coupé body with wide doors; at the same time the radiator does not project over the front axle. There are no levers on top of the steering wheel, the spark being fixed and the throttle controlled solely by a foot button.

The smallest four-cylinder motor on the market in this country is the Isotta, used in their runabout built under the French voiturette rules. Its bore and stroke are 65 and 100 millimeters (2.56 and 3.94 inches) respectively. Isotta, like Fiat, has not quite decided the chain versus shaft drive question to its own satisfaction, and has some of each.

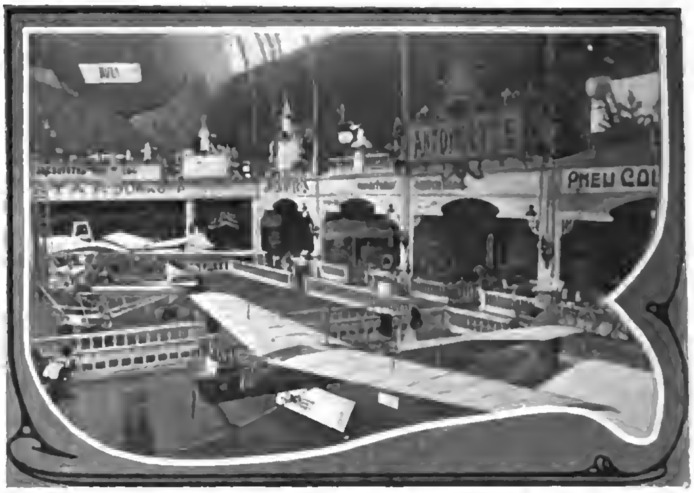
De Dion-Bouton is a prominent exponent of the single-cylinder motor for light runabouts, and has two models of this type. One of these is a standard design with bore and stroke of 100 and 130 millimeters (3.94 and 5.12 inches) respectively; in the other, built under voiturette rules, the stroke is 160 millimeters (6.30 inches). The latter is a remarkably fast car, and can take the measure of many four-cylinders of greater rated power.

Going to the opposite extreme, De Dion is building an eight-cylinder car of remarkably heavy and solid construction, with axles and frame which recall commercial practice. All De Dion models have two distinctive features, the three-plate clutch and the double shaft drive. In the latter, the gear-box and differential are exactly the same as for a car with double chain drive, but are located so that the jackshaft is just over the rear axle. The shafts which should carry the sprockets on their outer ends, are instead provided with two universal joints each and project directly into the hubs of the wheels, as in the regular full-floating rear axle. The axle itself is a solid I-beam.

Two models are featured by Panhard for American service, a four-cylinder town car and a six-cylinder touring model. The touring car has its cylinders cast separately but bolted together into a semblance of a block construction; the idea is exactly the same as that embodied on two well-known American cars.

Six-cylinder motors with the cylinders cast in threes are much favored in foreign practice, although the only American maker who tried this construction dropped it after one year. Those using the triplet cylinders are Delaunay-Belleville, on two models, and Renault on one. All of these are very small motors, the Delaunays being 72 by 85 millimeters (2.84 by 3.35 inches) and 72 by 105 millimeters (2.84 by 4.14 inches), respectively, and the Renault 80 by 120 millimeters (3.15 by 4.73 inches).

FROM THE EUROPEAN MAIL



Antoinette Exhibited Its Graceful Monoplane at Brussels

FRENCH AUTO SALON ASSURED FOR 1910

PARIS, Feb. 2—It is now practically certain that there will be an automobile show in Paris this year, for the constructors who eighteen months ago voted against the annual exhibition have just voted in private for the renewal of the interrupted annual event. When they voted against the show the constructors formed part of an association under the auspices of the Automobile Club of France, in which they had as companions accessory manufacturers and dealers, tire manufacturers, body makers and a host of others who figured largely on the voting list, although being comparatively unimportant financially. It was only by forming a solid body, and refusing to exhibit despite the vote that the automobile manufacturers had their way.

No date has yet been fixed for the show, nor have any regulations been drawn up. It is probable, however, that the event will be held late in November or early in December. It is impossible to hold it earlier, for the aeronautical manufacturers, who are also holding a show under their direct management, without the aid of outside club or association, have secured the Grand Palais in the Champs-Elysées from October 15 to November 2.

MANY FRENCH FACTORIES INUNDATED

PARIS, Feb. 2—More than any other industry has the automobile suffered by the floods in the Seine valley. At least three-quarters of the automobile factories of France are clustered on the low-lying banks of the Seine in the northwestern suburbs of Paris. When the river overflowed its banks and worked into the basements of all the factories, extinguishing the fires, nothing remained to be done but to close the doors. In several cases, indeed, the doors have been barricaded by water, making it impossible to enter the factory except by boat. Practically the only large firm not having suffered, and not likely to suffer, by the flood is Panhard & Levassor, whose factory is on high ground.

Renault was one of the first to close the doors of its factory, thus throwing 2,500 men out of employment. Voisin, the aeroplane constructor, being separated from the river by the width of the roadway only, was an early sufferer. Esnault-Pelterie, although further inland, soon had to abandon work. At Puteaux the Darracq, Unic, Saurer, Vinot-Deguingand, De Dion-Bouton, Mercedes, and Charron shops have all had to be closed. Among the body makers who are adversely affected are Védrine and Kellner. On the opposite bank of the river the Clément-Bayard works have only been kept open by the use of three powerful pumps and a brick wall hastily built to keep out the water. Santos-Dumont's private workshop is surrounded by a sheet of water and has had to be abandoned. The Antoinette aeroplane works have had to be closed owing to the impossibility of reaching them through the surrounding water.

IMPERIAL PATRONAGE FOR RUSSIAN SHOW

PARIS, Feb. 2—Russia will hold an automobile show for the third time in the Michel Riding Hall, St. Petersburg, from May 28 to June 9. The first event took place in 1907, the second in the following year, and the third is to be held after an interval of 24 months. The automobile outlook is promising in the land of the Czars, as there is a very large section of the wealthy population eager to take to the new mode of locomotion. The authorities are well disposed toward the automobile industry, and the main highways are being rapidly improved, primarily for military purposes, but at the same time for the benefit of the new industry. As a proof of the favor with which the automobile is regarded in high quarters, the Automobile Club of Russia has been given the right to incorporate the word "Imperial" in its title.

FRANCE MAKES TROUBLE OVER AERO DATES

PARIS, Feb. 2—Because an aeronautical meeting in England appeared to clash with French interests, the Commission Aerienne Mixte, the governing body in France, called a meeting, revised the calendar drawn up by the International Federation, and set it up to the superior body with the threat that it must be accepted in place of the list of events drawn up a week before.

The new calendar had struck out the English meeting, originally announced for July 11 to 16, and so modified the French dates that there was practically a continuous aviation meeting, under different managements, from June 19 to August 21. Although the second English meeting was allowed to retain its date from August 6 to 13, a French meeting organized by an enterprising Parisian newspaper was allowed to have exactly the same date. As no French aviator can take part in the first boycotted English meet, and is not likely to want to take part in the second one, in view of the greater attractions in his own country, the position allotted to England is not a very important one.

Naturally John Bull is furious, declaring that July 11 to 16 having been granted him, he will not release it without a struggle. If the International Federation decides for England, France will withdraw; if, on the other hand, it decides for France England will find herself in the impossibility of holding any meeting of more tban local importance. Whatever the justice of the case, victory appears to lie with France, for as she possesses practically a monopoly of aviators she can either enforce her wishes or defy the international body.

Tbe trouble arises from the fact that the Rheims authorities, the Automobile Club of France, and the Brussels aeronauts wish to work together with a series of meetings following one another without a break. As soon as the Rheims program has been pulled off, there will be a cross-country flight through the champagne country, over the northeast of France, and the Belgian frontier, to Brussels, the event being under the control of the Automobile Club of France.

The revised program comprises 11 international events, each having an assured prize list of not less than $40,000, and 16 national events offering smaller amounts in prizes. The total amount offered in prizes at these public meetings is $675,000.

M. BALSAN REMODELS HIS BLERIOT

PARIS, Feb. 2—Léon Delagrange's untimely death, as the result of flying a Blériot with a Gnome motor, has not prevented other aviators from employing the same combination. One of the most interesting of tbese has been brought forth by Jacques Balsan, who has replaced his 25-horsepower Anzani with a 50-horsepower revolving Gnome, and as a consequence increased his speed about 20 per cent. Unlike the Delagrange outfit, however, the Balsan aeroplane has been specially designed for the greater strain under which it will work. The four longitudinal frame members forming the main body of the aeroplane are united by two steel girder work crosses, one at the forward extremity and the other a little further to the rear. The motor is carried between these two, the external ball bearings of the crankshaft being in the center of the metallic cross. The propeller is mounted directly on the end of the projecting shaft.

A circular sheet-metal screen surrounds the radiating cylinders, at the same time concentrating the current of air on the motor and preventing the splashing of oil in the face of the pilot. Up to the present this has been one of the minor disadvantages of the Blériot aeroplanes, the pilots often being obliged to descend owing to the blinding spray of oil. The attachment of the wings to the body has been considerably strengthened and the wing-warping cables made more powerful.

Jacques Balsan and His Rebuilt Bleriot with Gnome Motor

ROCHESTER-SYRACUSE RUN MEETS SUCCESS

ROCHESTER, N. Y., Feb. 4—Of the twenty cars that left here on Wednesday morning as participants in the second winter endurance run of the Automobile Club of Rochester to Syracuse and return fifteen checked back last night with absolutely perfect scores. Still more remarkable—of the five penalties imposed not one was due to mechanical trouble unless cracked spark plugs be so called. Entry No. 5, a Model T Ford, with Claud Darling driving, was penalized for a broken porcelain and the consequent time consumed in making a change. The other four, Cadillac "30," No. 2, Ray Bettys driving; Selden, No. 6, William T. Barry, Jr., driving; Gaeth, No. 8, D. C. Anderson driving, and Maxwell Model "A", No. 24, Harry Veltz driving, were each penalized because of stalled motors.

The penalty inflicted upon the Selden was certainly one that

Chalmers "40" Held Up by Pace-Maker Amid Snow-Drifts

might well be termed hard luck. The car was perfect in every respect and had driven up to within 20 feet of the checking-out line and was standing idle with the motor running. In answer to the checker's signal to come ahead the clutch was slipped in, and at almost the same instant, the front wheels sank into deep snow with just enough jar to stall the motor. The little Maxwell also belongs in the same class, for the penalty imposed in this case was due to another contestant backing into the little car and thus causing Veltz to stall the motor.

The pacemaker was a Palmer-Singer 6-60, driven by Bert Van Tuyle, secretary of the Rochester club. The press car, entered at the last moment, was an Oldsmobile 4-cylinder, owned and driven by Thomas J. Northway, one of the prominent dealers of Rochester. This car was also of considerable value in assisting the pacemakers in opening the terrible roads. With representatives of THE AUTOMOBILE and MOTOR AGE in this car, were also, Walter A. Stewart, of the Rochester *Times*, and E. R. Partridge of the Rochester *Herald*.

In point of miles the run was short, being but a little over 200, going and coming from Syracuse, but there is no doubt in the minds of any of the participants but that the mileage covered offered more severity than three or four times the distance under ordinary conditions.

Starting Wednesday morning the run to Clyde was easy, as the roads were well cleared, but from Clyde through to Syracuse that afternoon, mere words seem but weak expression of conditions encountered. In two different places it was necessary to tear down farm fences, fill deep ditches with fence rails after digging out many feet of snow, and take to the farmers' fields for over a mile. Then, in the middle of one field, another deep ditch was encountered, and it required an hour for about thirty men with shovels and picks to clear out the ditch and fill it with solid rails.

On the return from Syracuse Thursday over the southern roads via Auburn and Geneva, the most terrible weather conditions were the rule. Early in the morning it started to rain; within the hour it was snow, and within two hours the thermometer had dropped to below twenty. Add to this a driving gale, bearing down from the northwest, squarely into the faces of the drivers, and some idea may be gleaned of the hardship of that second day's trip. Goggles were unavailable because of the snow, and after some of the boys had cut their faces to the point of bleeding, veils were bought and wrapped around the heads of the drivers.

Those cars with perfect scores will have to participate in another run, according to the rules of the contest.

ENTRANTS OF ROCHESTER-SYRACUSE ENDURANCE RUN

Order of Starting	Makes of Automobiles	Driver	Score
1	Chalmers 40	J. W. Ellis	1000
3	Cadillac 30	Edw. Martin	1000
4	Ford T	Fred Rockleman	1000
7	Selden	Jack Harrigan	1000
9	E-M-F	F. W. Peck	1000
10	Franklin	John Burns	1000

5	Ford T	Claud Darling	990

Palmer-Singer Pace-Maker Arriving at the Clyde Control

Cadillac Number 2 Checking Out, with Others Ready

NEW MOTOR OF MERIT IN ACCESSORY FIELD

SO GREAT has been the demand for accessories, and in particular what might be called the major accessories, exceeding by far the supply, that the entry of any well-equipped firm into this line will be welcomed by all makers of automobiles not building every part in their own shops—and their number is legion. So it is, that the entry of the Chester Engineering and Machine Company, of Chester, Pa., into the accessory field with a pair of very neat block engines, will be singularly welcome. This firm, located at Front and Penn streets, in Chester, has a large and well-equipped shop, the whole extent of which is now being turned over to the construction of automobile and marine engines, whereas previously, a number of other parts were built. This previous experience is of value, in that the firm is not to be classed with the untried and untested.

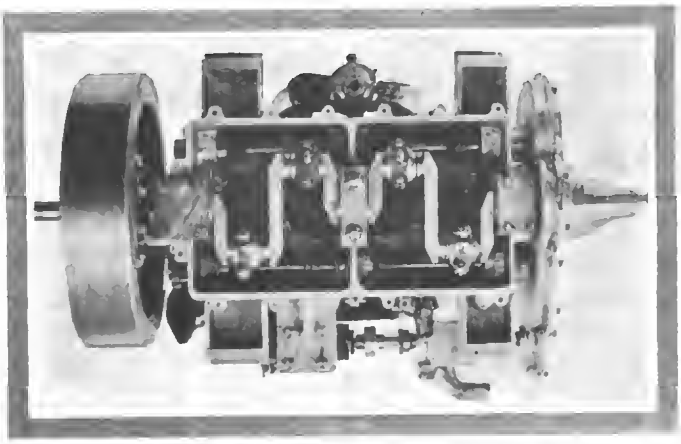
Two models of engines will be built, these varying mainly in size, the design being common to both. This motor is known as the Penn, and is of the four-cylinder, block type, with tee heads. The smaller engine is illustrated herewith, the size of this being 3 9-16 in. bore by 4 3-4 in. stroke. In adopting the block construction and the very long stroke, the firm has shown a commendable knowledge of the latest in motor design, both at home and abroad. This bore and stroke give a ratio of 1 to 1.33, which is above the average of long strokes, and very close to the highest ratio now in use in this country. This very long stroke should result in the development of power at very low speeds. Since this is easy on bearings and other wearing parts, the result to the user should be long life, and small upkeep expense, as well as fuel economy.

Despite the compactness of the block construction, the crankshaft has three bearings, the middle one being fairly liberal considering the circumstances. The end bearings, on the other hand, are very long, so that the total length or area of bearing surface is very large in relation to the size and power of the engine. Although of the block type of casting, the space between the lower parts or barrels of the cylinders is not solid metal, but is cored out, thus securing lightness and superior cooling ability.

Power rating is according to the usual formula, so that the engine is called a 19.6 horsepower unit. As a matter of fact, however, the engine develops over 20 at 1,100 and has developed as high as 26.8 horsepower at 1,200 revs. This extreme power output is rendered possible by large valves, the size of the clear valve opening for this small engine being 2 in., which is far in excess of that usually considered as a maximum, namely, half of the cylinder diameter. The latter figure in this case would be but 1 3-4 in., so it is seen that the valve size is very unusual. Large valves give a low lift for the same volumetric area of opening, which, in turn, makes for extreme quietness. This is one of the factors which have made this motor very silent in its action.

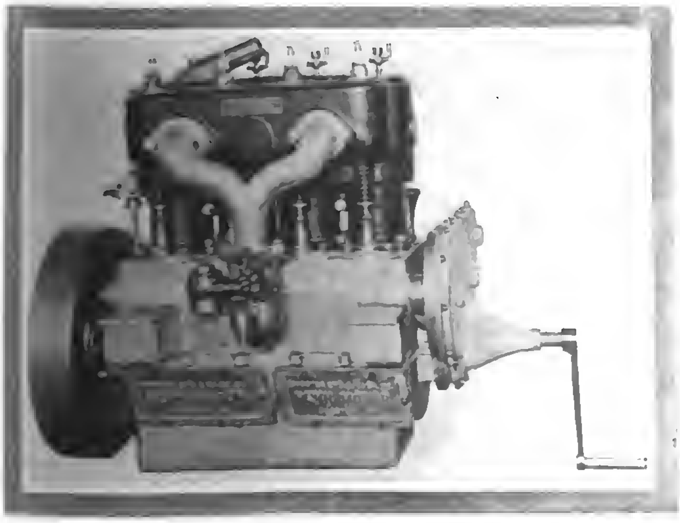
Cooling is by centrifugal pump, although the proportioning of the water pipes was done with the idea in view of utilizing thermo-siphon cooling when so desired. The pump is located on the right-hand side, together with the magneto. The latter is supplied as regular equipment. Lubrication is by the constant level splash system, the level being adjustable by means of a handy screw. This allows the driver of the car to regulate the amount of oil used, a feature not present in other engines.

One feature not observable in the pictures shown, is the starting crank arrangement. This is such that the cranking handle is always held in one position, at the left. When desired to crank the engine over, it is simply pushed into engagement. When the cranking is concluded, the crank may be allowed to swing, as it will automatically check itself, and catch at the left in the usual position. This is a far superior arrangement to a strap, which necessitates loosening and removal for use, and loosening and replacement after use.



Magneto Is Conveniently Located on the Exhaust Side

A larger motor is also built along very similar lines, in fact, to the same design. The size of this prime mover, rated at 30 horsepower, is 4 1-4 in. bore by 4 3-4 in. stroke. This is comparatively shorter than the small engine, but still long enough to bring it into the long stroke class. This motor, too, is of the block type, with tee-head cylinders and 3 crankshaft bearings.



Inlet Side of Penn Motor, Showing Carbureter and Pipe

ANOTHER CHAPTER OF GOSSIP FROM DETROIT

DETROIT, Feb. 7—Further evidence of the prosperity being enjoyed by automobile interests is furnished by the increase in capital stock from $1,800,000 to $2,500,000 just announced by Morgan & Wright Company, manufacturers of tires and rubber goods. The firm established its plant in Detroit in 1906, and J. C. Butler, president, declares the demand for automobile tires, principally in Detroit, is responsible for the increase in capitalization, all of which has been paid in cash.

In this connection figures compiled by the official statistician of the Detroit Board of Commerce furnish a striking object lesson in the growth of the automobile business locally, and what it means to the hub of the industry. During the year just closed there was an increase in capital in the various corporations, including new ones to enter the field, from $5,700,000 to $15,200,000. During the same period there was an increase of employees from 8,430 to 14,900. During the year 45,500 cars were built in local plants, with a valuation of $54,300,000, compared with a total valuation of $23,600,000 in 1908.

The Dominion Motors Company, Ltd., has been organized, and will establish a plant in Windsor, just across the border on the Canadian side. Detroit and Canadian capital is financing the enterprise, and experienced automobile men from this city will be in charge of affairs. Operations will be commenced at once, and it is hoped to build 250 cars the first year, the machine being known as the Royal Windsor. Canada has long been looked upon by American manufacturers as an inviting field. A duty of 35 per cent is imposed on all automobiles taken into the Dominion from the United States.

Van Dyke Motor Car Company, Frank G. Van Dyke, president, is out with a delivery wagon with a capacity rating of 1,000 pounds. The plant, which will be located at Detroit, is to be a large one. The area is to be 130,320 square feet and the main building will be 704 feet long. A delivery wagon, the first one out of this make, created quite a lot of healthy excitement at the Detroit show, and reports have it that the demand for this wagon is pronounced. The motor is double-opposed, 4 3-8-inch bore and 4-inch stroke; magneto ignition, and the control will include a friction drive. Geo. P. Davis, consulting engineer of the company, is the designer. In the handling of the company business a service station system will be maintained—service will be guaranteed.

The Lozier Motor Company of Michigan, is now in control of the holdings of the Lozier Motor Company of New York, this action having been taken at Plattsburg, N. Y., last week. The transfer was made on the basis of $493,710 in cash or $822,850 in fully paid non-assessable captial stock at par in the Michigan corporation, in addition to which Henry A. Lozier and Edwin R. Lozier are to get $160,000 in cash or $200,000 in the non-assessable capital stock at par, the duly authorized officers of the Lozier Motor Company, of New York, also to receive $106,290 in cash or $177,150 in stock. It is announced that work on the Detroit plant will be begun as soon as possible.

The Chalmers-Detroit car has now passed into the realm of history. Henceforth that popular car is to be known as plain "Chalmers." This step is officially announced by the Chalmers Motor Company, the reason being assigned that it is desirable in order to avoid confusion with the great number of new cars which have incorporated "Detroit" into their names.

There is another class of scouts of whom little is heard, but who are a recognized part of almost every factory force. These are the men on the lookout for skilled mechanics, for whom there is the keenest demand. They keep in touch with the avenues through which machinists, toolmakers, in fact all kinds of skilled labor, find their way to Detroit, and offer inducements to have the men enter their plant.

The newly organized Owen Motor Car Company has purchased a three-story brick factory building on North Grand Boulevard, adjoining the Packard plant, together with six acres of land. The company is capitalized at $500,000, with $250,000 paid in. It is proposed to build 500 cars the first year, and in the spring work will be begun on a reinforced concrete factory that will increase the capacity to 1,000 cars per year.

Local auto makers are rejoicing over the action of transcontinental lines in rescinding the recent raise in rates on automobiles for Pacific Coast points from $3 to $4 per 100 pounds. On every car sent to the coast this meant the imposition of a tidy sum which either had to be met by the manufacturer or tacked on the selling price by the dealer.

The United States Auto Top Company has been incorporated, with a capital stock of $20,000. The incorporators are W. A. Paul, F. A. Hood and L. S. Anderson.

Grant Brothers' Foundry Company is another new industry, the promoters of which are Charles A., George D. and W. W. Grant, of the Grant Brothers' Auto Company, and Vital Ouellette.

F. H. Trego, secretary of the Chicago Motor Club, and a well-known automobile expert, has joined the ranks of the Hudson Motor Car Company and will be associated with Vice-President and Chief Engineer Howard E. Coffin.

MINNEAPOLIS SHOW WILL OPEN FEBRUARY 19

MINNEAPOLIS, MINN., Feb. 7—Indications are that the third annual automobile show to be given under the auspices of the Minneapolis Auto Show Association, February 19 to 26, inclusive, will be the biggest event ever held west of Chicago.

Notwithstanding there are close on to 25,000 square feet of space available in the National Guard Armory, where the show is to be held, those interested in these annual motor exhibitions are afraid that there will be a shortage of room, and plans are already being discussed looking to the securing of larger quarters for the show in 1911. Already the list of exhibitors for this show exceeds that of 1909 by at least 80 per cent. The space on the main floor of the big armory has all been taken up and on this floor alone upward of 70 bonafide automobile dealers will show. It is estimated that one hundred makes will be exhibited.

There is besides this floor, a spacious basement, which will be used for the exhibition of the heavier class of motor vehicles, such as motor trucks, delivery cars, etc. The space here, too, is being taken up rapidly, and a complete assemblage is promised.

When it is known that there are upward of 50,000 cars now running within the territory of which Minneapolis is the gateway it can be realized how important this show will be to the motor industry of the Northwest. Dealers, buyers and everybody interested in motor cars in the States of Minnesota, North and South Dakota, Montana, Western Canada, Iowa and parts of Wisconsin will be at this show. About 45,000 persons saw the show in 1909, but the present indication is that twice that number will pass through the gates during the week of the show

Following so closely as it does the Chicago show a large number of automobile dealers who will have exhibits at the Windy City event will ship their exhibits direct to Minneapolis.

The officers of the Minneapolis Auto Show Association, who have the affair in charge, are: H. E. Pence, of the Pence Auto Company, president; H. E. Wilcox, of the Wilcox Motor Company, vice-president; F. E. Murphy, of the Minneapolis *Tribune*, secretary, and Walter R. Wilmot, manager.

MITCHELL HEAD REPORTS PROSPERITY ABROAD

BACK from an automobiling trip in Europe that was productive of much valuable information as well as brimful of pleasant experiences, Captain William Mitchell Lewis, president and general manager of the Mitchell Motor Car Company of Racine, Wis., and G. Vernon Rogers, its secretary, traversed a little more than 2,000 miles of diversified roads ranging from the broad highways of England to the mountain roads of the Pyrenees and the mediocre roads of Spain in the Mitchell six-cylinder machine at the wheel of which sat René Petard, European representative of the Mitchell company.

"We toured from London to Folkestone," said Captain Lewis, "thence from Calais to Paris, and over the Pyrenees to Barcelona, Spain, and back to the French capital, with no motor or mechanical troubles, considerable comfort, and much enlightenment. The American-made cars are enjoying a wonderful amount of popularity in continental Europe and in the British Isles. I am pleased to state, also, that the Mitchell car, one of the pioneers in tthe American invasion, not only is having a big share of this but is in the lead of all others.

"While in London we closed a contract with Lavey Brothers, 20 Conduit street, for a period of five years, the British concern agreeing to take $500,000 worth of our cars. While in London we visited the Olympia show, the largest and best automobile exposition ever held. The success of this show has taught the continental makers, especially the French and German manufacturers, their great mistake is not holding the usual big annual expositions that have served to direct the attention of the world to their wares. As a result of the lesson given to them, the French makers are even now planning for a huge Paris salon in November or December, 1910, to offset the depressing effect of the failure to hold the Salon this year. Germany also is figuring on a great show revival, while the French makers who now realize the lack of wisdom in abolishing great track and road-race classics, are planning a race revival upon one of their big schemes.

"I was impressed by economic problems presented by the European situation. The continent has not the motor purchasing public that the United States has, although in France the national records show that the wealth per capita is more evenly distributed than in any other country abroad. In England there are many poor and also many rich. But the great class that might be depended upon to absorb motor cars is that element which the Britons refer to as 'in trade.' The tradesmen are perfectly able to purchase cars, but they refrain from doing so rather than have it appear they are aping the royalty and aristocracy. The contrast in America is rather marked to the traveler—imagine the business man of the United States going without an automobile if he wished one—and he has the money to buy the car.

"You are struck abroad and especially in London by the number of taxicabs and commercial vehicles. The field is a great one. Before I left there Gamage Limited of London were just negotiating a contract for putting 3,000 more taxicabs on the streets of Greater London, which has 3,000,000 more population than Greater New York and not nearly as many motor cars—and so important has the taxicab problem become that they are starting schools for the education of cabmen's children for the avocation of the chauffeur. The horse-drawn vehicle is rapidly becoming a thing of the past in London.

"While in Spain we closed with Rossello y Mas, 20 Plaza de Tetua, for 25 Mitchell cars. The Spanish automobile agent has a beautiful country estate near Barcelona to which we motored. Near it is a church built in 625 A. D. containing the sarcophagus of a daughter of a former king of Spain."

AUTOMOBILES IN ENGLAND ON INCREASE

From a statement recently issued, based upon official statistics, the following table, showing the number of motor vehicles of all kinds, including public service and motor cycles, in use in the United Kingdom on September 30, 1908 and 1909, has been prepared:

	Total of all kinds.	
In use in	1908.	1909.
England and Wales	137,323	163,181
Scotland	10,907	13,093
Ireland	6,186	7,499
Total	154,416	183,773

	Private motors.	Trade motors.
In use in	1909.	1909.
England and Wales	74,748	13,961
Scotland	6,157	1,056
Ireland	3,933	164
Total	84,840	15,181

The foregoing shows an increase of 29,358 in the total number of vehicles during the last year, which was largely due to the more extended sales in England and Wales. The increase in private cars was 18.8 per cent. According to the statistics, the number of public service cars increased 48.8 per cent. and motor cycles 15.3 per cent., the number of the latter being given as 75,000. These results indicate an increasing demand for motor vehicles, and especially for cabs for public service and cars used for commercial purposes. It is confidently predicted by many that in a few years the number of business vehicles will exceed those used for pleasure.

As to private cars, there was an increase of about 13,435 during the year. Present indications are that cars of small and medium power will predominate during the coming season. Modern improvements in motor cycles, to prevent vibration and noise, will assist this branch of the trade, and it is believed that the coming year will witness an increase of 25,000.

OWNERS' GASOLINE STORAGE PROBLEM

Automobile owners have been handicapped in many ways, but it is doubtful if they have ever been confronted with a more perplexing problem than the safe storing of gasoline. This phase of the automobile business has caused many people sleepless nights of worry. They were continually harassed by the fear that the city fire regulations were not being lived up to. Explosions were feared and dreaded, and an innovation which would sweep all this away was hailed with delight.

Such an innovation received its inception in Pittsburg, where the city officials, constantly on the lookout for infringements of its strict fire regulations, endorsed the project as the best that has been put on the market. That the air-tight steel gasoline tank is not liable to an explosion was demonstrated after the careful inspection made by the city experts.

No city can boast of more strict fire regulations than Pittsburg. The peculiar formation of the downtown section, so closely built up, caused these severe restrictions, and it was with careful regard for these laws that the air-tight tank was finally picked as the safest. Three departments were supplied with them, the Departments of Public Safety, Public Works and Health.

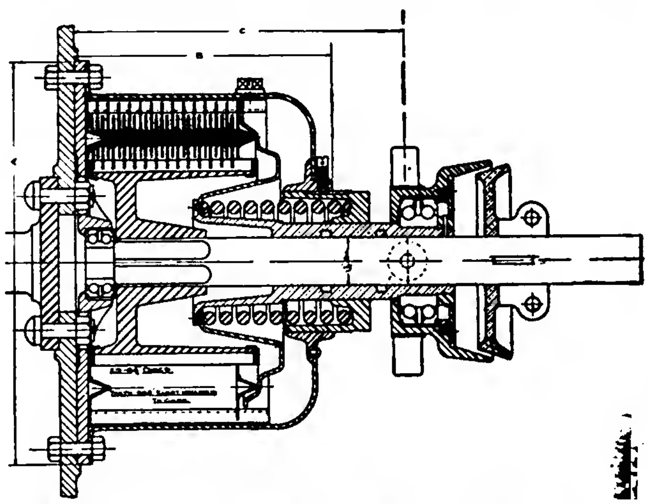
It is recognized among automobile owners and other users of gasoline that this necessary adjunct to the operation of the machine is highly explosive. Its storage was the problem with which auto owners grappled for so long. But with the coming of the air-tight tank, the problem has become no problem at all.

Pittsburg's strict fire regulations were taken into consideration when the air-tight tank was first broached as a possible purchase by the city departments. Its merits were thoroughly looked into before the city ventured to put the seal of approval on them hy purchasing them. It was deemed safe to put two of the tanks within the fire limits, while the third was placed at the Department of Health stables in Frankstown avenue, East End.

HELE-SHAW CLUTCH HAS NOVEL M. D. FEATURES

MULTIPLE disc clutches are now so thoroughly well known for their varied and excellent qualities in connection with automobiles, that the improvements which are being made from time to time are interesting in the extreme. The Hele-Shaw clutch, of which a cross section is here given, represents one of the types in the multiple disc family, which has sustained its reputation, and is being taken up by car builders of exacting ideas. As the section clearly indicates, the discs are considerable in number, they being utilized in proportion to the power which must be transmitted, and the outer discs are the driving members, they being fitted to inwardly projecting driving faces, which are integral with the housing, which, in turn, is flanged to the flywheel. The driven discs are on a drum with outwardly projecting driving faces, and the spider of the drum ends in a suitable hub, which is broached with a square hole, which in turn engages the squared end of the driven shaft. The driven shaft is surrounded by a sliding sleeve, and the clutch spring is concentric with the sleeve. A drag brake is shown to the rear of the clutch proper, and when its conical faces are engaged, the slight amount of inertia which might be felt when the clutch is relieved, is overcome by the drag of this supplementary clutch. This is a detail which is well worth looking after.

The Merchant & Evans Company, with headquarters in Philadelphia, Pa., in addition to meeting with good success in the exploitation of the Hele-Shaw clutch, is handling a line of front and rear axles, transmissions, and other specialties, all of which



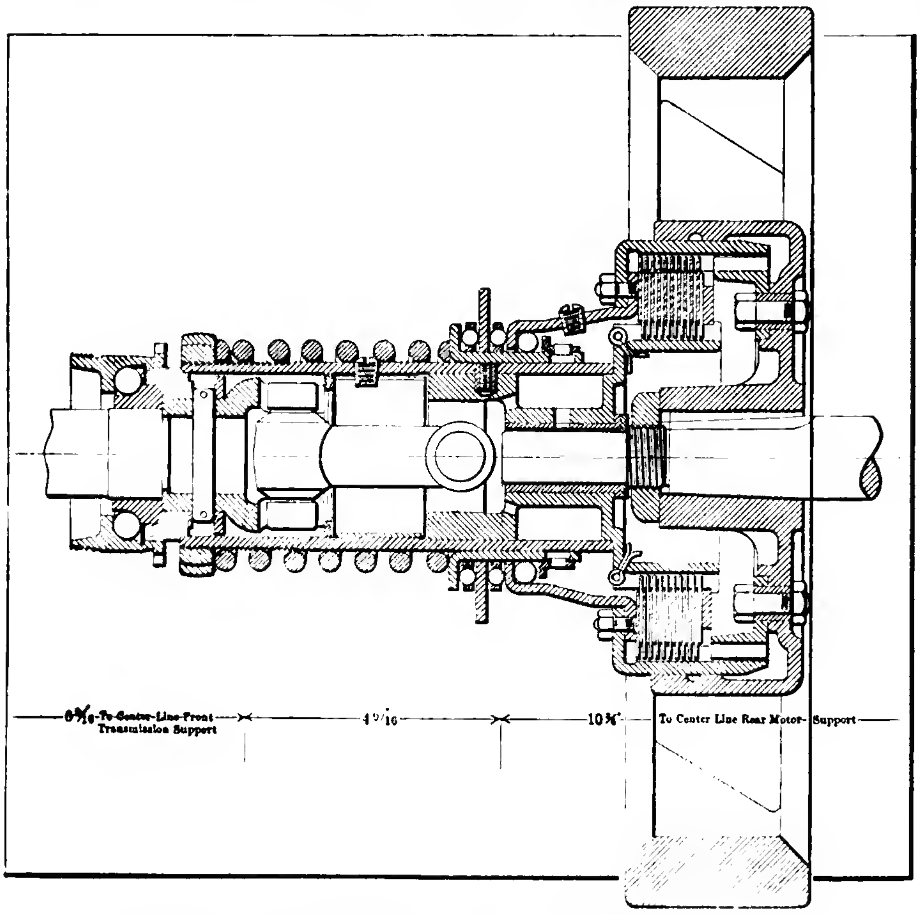
Section Through Hele-Shaw Disc Clutch Showing Discs

are now much in vogue and well known to builders of automobiles of the class which provides a residence for quality.

REO MULTIPLE DISC CLUTCH AND JOINTS

DESCRIBING a whole automobile offers the disadvantage of saying so much that memory fails to grasp the situation from the point of view of details. In the long run it is the detail which will be found at the seat of trouble, and for the best result it is more profitable to discuss details one at a time to bring out the gist of the story. The subject here taken is the clutch and universal joint in the Reo 4-cylinder automobile for 1910, and attention is called to the presence of the universal joint inside of the shell around which the spring is placed. The shell connects with the crankshaft through the discs, but the transfer of power is through the universal joint, which, instead of being placed back of the clutch unit, as it is in many makes of automobiles, is housed in, away from accumulations of foreign matter, and lubrication is easy of accomplishment.

Among the other features which will be found in this unit are: The large size of the spring used to apply clutch pressure; ball thrust bearings to take the reaction of the large spring; pipe plugs which may be unscrewed if it is desired to add to the supply of grease within the housing, and such other features as will add to the good qualities of the unit. The flywheel is placed on the crankshaft by being fetched up on a taper, and a key is there to resist the torsional effort. In assembling, the pin back of the universal joint is readily removed, and the bolts which hold the clutch housing to the flywheel will also facilitate the operation. In divers other respects the assembly as here depicted has novelty in its makeup, and stability besides.



Construction of Reo Multiple Disc Clutch as Revealed in Cross Section

VOL. XXII NEW YORK—THURSDAY, FEBRUARY 17, 1910—CHICAGO No. 7

THE AUTOMOBILE

METERING out the accumulated knowledge gained within a year is the process which is now being projected in the form of shows, following the two more pretentious efforts in New York, a very successful exhibition at Detroit, and the Ninth Annual National Show, which terminated at Chicago with great success on February 12. The further activity will be in the form of equally im-

EXTERIOR OF HARTFORD ARMORY AND A CORNER OF THE SHOW WITHIN

portant shows, beginning with Buffalo and including Hartford, St. Louis and Rochester, February 14-19. The remaining seven shows will include Washington, February 15 to 19, inclusive; Grand Rapids, February 17 to 19, inclusive; Minneapolis, Newark, Los Angeles, Salt Lake City and Cleveland, with dates from February 19 to 26 inclusive. Cleveland, however, will have two separate shows, one of which will be held at the Central Armory and the second will be held under the auspices of the Cleveland Automobile Club.

The large exhibitions are of the greatest possible value in an effort to indicate the enormousness of the automobile industry, but they offer the disadvantage of congestion, and the patrons of the industry are prevented from examining the products in detail with a view to judging as to their qualities, discriminating as between the methods of the respective

MAIN AISLE OF HARTFORD SHOW, VIEWED FROM OPPOSITE ENDS—THOMAS APPEARS PROMINENTLY

schools of design, and tabulating the relative facts in the mind for convenient use at the propitious moment.

Among the strong reasons why the lesser shows present positive advantages are those which are reflected by an examination of the situation as it obtained at Chicago, in which 78 different makes of automobiles were lined up, with from two to five models of each make there to be examined. The total of the cars was 211, which is equal to saying that an interested spectator would have to examine 35 automobiles per day to cover the ground, and he would only be permitted to take substantially 15 minutes in the examination of each automobile. This schedule would leave no time whatever to devote to the examination of the major accessories, of which the automobiles of this year are so largely constituted, and as for the minor accessories, or accessories of convenience, it would not be feasible to devote to them a single thought.

In going into the shows which offer a wider opportunity for an inspection of the automobiles exhibited, it will not be without profit to have in mind just a few of the statistical characteristics of the automobile industry as a whole. It has been conservatively estimated that the product of the year will be approximately 280,000 automobiles, and the money exchange of the year foots up to the enormous sum which is just under $500,000,000. The automobiles which are being made would string out in a row to the close approach of 650 miles, and the passenger carrying capacity, taking them as a whole, would not be far from 1,200,000 adults. Thirty million dollars have been expended in factory buildings, and they cover 2,500 acres of ground, one of which plants, for illustration, reaches over an area of 101 acres.

It is fortunate for labor that upward of 120,000 skilled artisans are engaged, they having been recruited from congested industries, notable among which should be listed the machine tool zone of activity. These men will receive for their direct share the near approach of $100,000,000, which as a tax on the whole people might be stated in a homely way as equal to the purchase price of a dozen loaves of bread per inhabitant. The value of the industry to the country as against this relatively insignificant tax upon the individual resources, putting it in the same homely terms, reaches a figure which is scarcely within the realm of comprehension, it having been figured as equal to the value of 1,000,000,000 loaves of bread.

Under ordinary conditions men who do things as the men who command the rank and file which is engaged in producing automobiles, are prone to forget the foundation, and in allowing themselves to be lauded for their activity depreciate the value of the stable structure on which the whole rests—the patrons of the industry.

That users have been loyal to their ideals, despite the many disappointments, is the prime reason for the greatness of the automobile industry as it stands to-day, nor could the cars which are in fettle for a close inspection be placed on parade, were it not for the peculiar characteristic of men who buy; each one of them, almost without exception, has maintained that the automobile he invested in was the most suitable for him, even granting (which he is rarely willing to do) that some other make of automobile is superior in certain respects, which, however, is beside the question as he sees it.

It is this loyalty on the part of users which makes it possible for investors to build millions of dollars worth of automobiles even before there is any attempt made to ascertain if there is a buyer for each one of them, although absolute ruin would follow were purchasers to balk.

It is this certainty of success from the selling point of view that brought the quality of automobiles up to the present standard, and which assures that the standard will be advanced by easy stages, year after year. The few who have waited for a condition of ideal perfection before making a purchase were mostly of the class who would have to deprive their children of reasonable comforts had they done otherwise, and the very condition which induced them to hold back has proved to be a blessing in disguise.

The automobile industry, taking it as a whole, is in the hands of men who fully appreciate the value of a reputation; they know very well that a "run," while it is closely associated with banking, has a synonym; that lack of confidence will lead to a slump, and that it is necessary to maintain a high standard in order to be successful. Fortunately, the very worth of the automobile, the divers uses to which it may be profitably put, adds stability to its manufacture, and this condition is enough to induce money to come to the rescue of the maker who knows the worth of quality, and who employs the brains and the brawn which is capable of doing the work.

That time is practically at hand when the automobile will be a standard product, ordered without the necessity of seeing the finished article; the automobile dealer will call for a consignment of cars, specifying merely the seating capacity and power, confident that when received they will answer his requirements. Although shows may in this way lose some of their importance, they will continue to do valuable missionary work. Their spectacular features form a most valuable attraction.

LOCAL SHOWS FLOURISH THE COUNTRY OVER

FOLLOWING the great National exhibitions in New York and Chicago, the present week finds a number scattered over the country. In the East, Hartford, Conn., is having its exposition, under the management of the local dealers' association; New York State has two, at Buffalo and Rochester. In the West, St. Louis dealers are having their annual inning. The Grand Rapids, Mich., Automobile Club will open its show in midweek on Thursday. To next week belong, in reality, those opening on Saturday, February 19, namely, Minneapolis, Minn.; Newark, N. J.; Los Angeles, Cal.; Salt Lake City, Utah, and Cleveland. In Hartford, Conn., the third annual automobile show of the Hartford Automobile Dealers' Association opened at Foot Guard Hall, Monday evening, and continues for a week. The home of the famous crack military command presented an animated appearance. This notable hall has housed many attractions in its day, but none of more importance to the City of Hartford, from a commercial standpoint at least. The Hartford Automobile Dealers' Association proved conclusively on two former occasions that, notwithstanding the proximity of this city to New York or Boston, a local automobile show could be conducted as a successful venture if it was only done in the right way. The association discovered the right way three years ago and has made good on three successive occasions.

Within the past few years the automobile trade has increased by leaps and bounds and Hartford has become the mart for the smaller towns for miles around, so that although the city has a population of but 100,000 it serves in reality as the center for twice that number. The cars on exhibition range in price from $500 to $5,000, and the aggregate value of the cars shown is estimated at $100,000, although in a comparatively small building. The main floor is given up to car display, together with the stage, the two rooms off the main floor, and a portion of the basement. The balconies are devoted to the display of accessories.

The committee tried to serve up something a little different in decorations this season, and succeeded. The effect is colonial, and even the uniformed attendants are dressed in the costumes of the time of Washington, with powdered wigs and all that sort of thing. Above the stage proper is a balcony which is made to represent the balcony of one of those colonial mansions which all are familiar with. The effect is well carried out. The sign posts of the various booths are of the same style.

To make the show the more entertaining the Foot Guard orchestra holds forth in the elevated balcony, and then, too, there are other attractions a bit out of the ordinary. The Tempo male quartet, which is one of the best of the sort in this section of the country, is also in evidence.

But as to the show itself. On the right of the main entrance is the Jackson stand, with two snappy models shown by Kilby & Bassett. On the opposite side is the Mitchell, followed by the Maxwell, in six different models. The Baker electric is exhibited by the Electric Auto Station; this is the first appearance of this vehicle in Hartford. Next to the Jackson exhibit is that of the Miner Garage, where are shown two models of the Pierce-Arrow and two Buick pleasure cars and a delivery wagon, this latter being much in favor. The Pierce has grown to be regarded locally as one of the most reliable cars and the representation has increased materially since the show a year ago.

Next to the space of the Maxwell is that of the Palace Automobile Station, agent for the Thomas, Studebaker-Garford, E-M-F, Flanders and Waverley electric. Here are shown a Thomas town car with a brougham body, a Thomas Flyer touring car, a Studebaker-Garford touring car, a Flanders roadster, runabout and chassis and an E-M-F chassis. The little Flanders was a matter of much interest to the crowd, who lingered about this booth in goodly numbers. Opposite the Thomas exhibit is that of Brown, Thomson & Company, who show the Cadillac touring car and a chassis in which the parts are exposed and in operation. One of the snappiest appearing cars in the show is the Briarcliff model Lozier, on this stand; the little six Lozier is also popular. The Stevens-Duryea is shown by the same firm in models X and AA.

Upon the stage, where it has now reposed on three different occasions, is the Ford line shown by the Elmer Automobile Company, including a touring car, runabout, coupe and town car. The Ford shares the stage with the Reo, which comes back after an absence of a year. The Knox is shown in one touring model on the same stand. Off the main floor, in the south

COLONIAL DAYS RECALLED BY THE NOVEL DECORATIVE SCHEME OF THE HARTFORD DEALERS' SHOW room, appears the Elmore in three models, not the least interesting being the new model "46" with the differential or two-diameter pistons. This car attracted much attention and the two-cycle advocates were numerous. On the north side of the hall in the room off the main floor the Rambler is shown by Foster & Company, of this city, who took the agency for this car a few months ago.

Down in the basement are shown several cars that have proved to be attractions. The little Hupmobile was one of the most interesting cars on exhibition. It is shown by C. K. Hansen, a local garage man who has built up a good business in the past two years. The Empire "20" is another newcomer and is shown by Kaeser & Wilbur, of West Hartford, who recently entered the field with very bright prospects. Several sales have already been made. The Franklin is shown by S. M. Hutchins and is as popular as ever. The air-cooled proposition has many followers in this city, and the Franklin is, by the way, the only air-cooled vehicle in the show. The Everitt "30" is shown by the J. T. Curtiss Company, and so is the Velie—both newcomers.

To make the week the more interesting from the autoist's point of view, the Connecticut Automobile Show Association is holding a show at the First Regiment Armory. Here the decorations are not so lavish, though there is far more available floor space on the one floor than is to be had at Foot Guard Hall. The decorations are simple yet effective, and one of the best bands in the State is on duty, rendering all the popular strains for those who come to view the cars.

Here is shown the Houpt, a product of which Connecticut is proud. A 60-horsepower stripped chassis is shown as well as a toy-tonneau car. This is finished in red, and is the highest powered car on exhibition here this week. The McCue and the Staver appear, both in touring models. The Jackson, which is on exhibition at the dealers' show, is also here. Matheson comes to this city for the first time and is an object of much interest. Two Corbin models are shown, as well as the Cameron and Moline. The Belmont is another new Nutmeg product and is shown in this city for the first time. Then, too, the Winton is on view. With two shows in full swing, in addition to private exhibitions, needless to say there is much doing locally this week. The various dealers without exception report a rushing business; there have been a great number of actual sales.

BUFFALO INCLUDES A LIMITED NUMBER

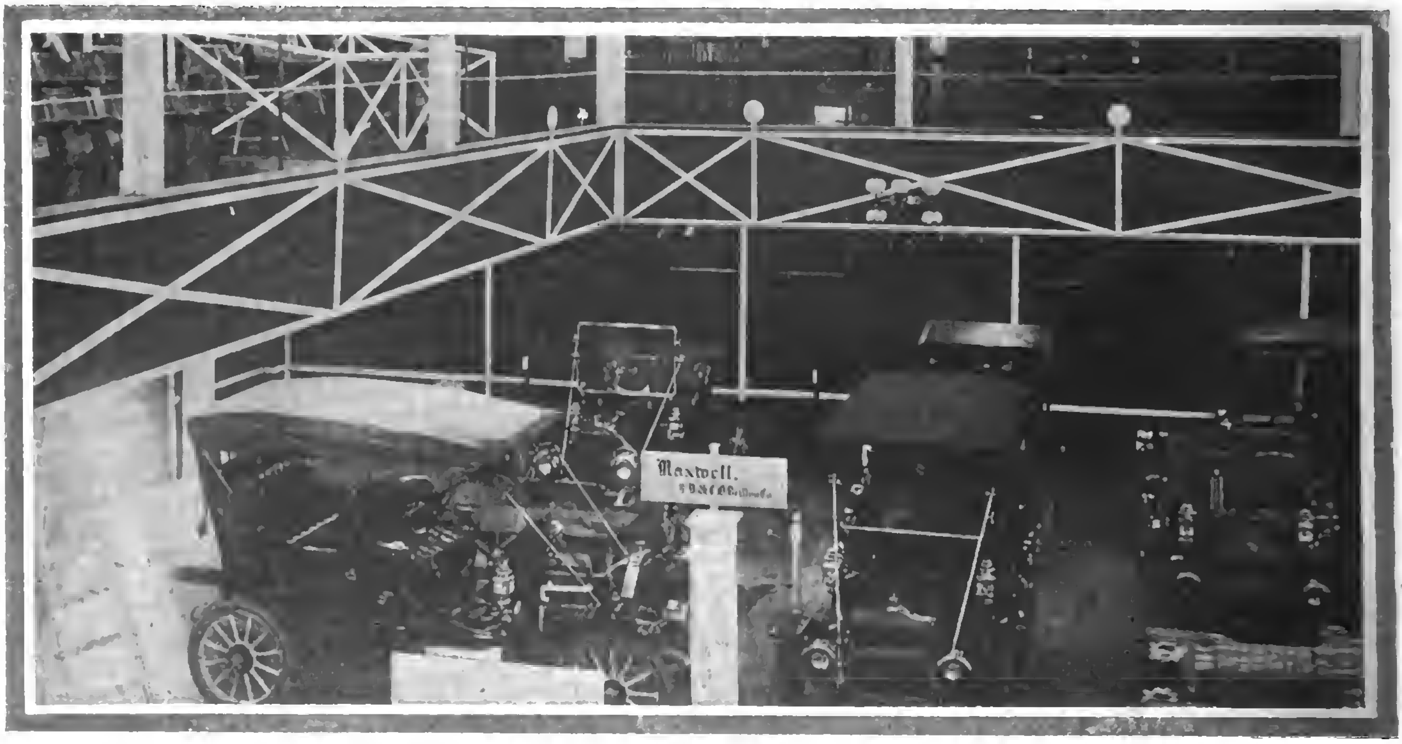
At 8 o'clock Monday evening a bugler sounded the assembly from the balcony of the Broadway Arsenal. At the signal, Mayor Fuhrmann, flanked on the right and left by Charles F. Monroe, president of the Automobile Trade Association, and Laurens Enos, president of the Automobile Club, pressed an electric button. The slight pressure turned on the electric current, and in a twinkling illuminated the Armory with the radiance of a multitude of electric bulbs. The lights rippled and blazed along the folds of the flag that spanned the entire roof of the drill hall, and the exhibitors and visitors bared their heads while the Seventy-fourth Regiment Band played "The Star-Spangled Banner."

The flag, the largest in the world, was the keynote of the decorations. Its symbolization was of the fact that there were only American-built cars in the show. The patriotic suggestion was carried out in the decorations which concealed the walls and even the windows of the dingy Arsenal. National shields decorated the burlap that hid them, and rosettes in the national colors festooned the spaces between the shields.

The Curtiss aeroplane that seemed to float in midair under the folds of the flag was an effect calculated as much for its decorative value as for its drawing power as a curiosity. The machine was too far aloft to afford the curious an opportunity to study its details. It attracted considerable interest, but did not detract from the principal business of the evening, the study of the 1910 models of automobiles.

There was little in the way of ornamentation to distinguish one exhibit from another, save for the difference of space. The signs were uniform in size and shape, consisting of national shields containing a gilt field in which the names of the exhibitors were printed in blue letters. The signs were on standards 8 feet high. Some of the exhibits were on a very large scale, which worked toward keeping their number down, despite the large floor area. There were in all but fifty-two exhibits, including approximately two hundred cars. There were as many more applications for space before the show was opened, but as it was alloted a month ago the latecomers were disappointed.

The Bison Motor Car Company occupies two spaces with its exhibits of K-R-I-T and Abbott-Detroit cars. The Pierce-



HARTFORD'S ATTRACTIVE MAXWELL EXHIBIT, INSTALLED UNDER THE OVERHANGING COLONIAL BALCONY

COLONIAL BACKGROUND, HARTFORD EXHIBIT OF THOMAS, E-M-F, FLANDERS, STUDEBAKER AND WAVERLEY

[illegible] Company occupies three spaces, with four Pierce-Arrow [illegible] a painted chassis. The Stoddard-Dayton exhibited a [illegible] chassis and five 1910 models, together with the torpedo [illegible] runabout. The same agent displayed alongside these [illegible] cars. Three types of Cartercars and a chassis were [illegible] Two Inter-State cars and an Empire car were shown [illegible]. The Franklins were out in three types, together [illegible] and a torpedo runabout. The Buicks turned out [illegible] of these cars filling six exhibit spaces.

[illegible] Stevens-Duryea cars and a polished chassis shared [illegible] with two Hudsons, three Knox touring cars, a Knox chassis and a torpedo runabout. The flock of Chalmers-Detroit "Bluebirds" numbered five, with the "30" and its driver Joe Matson and the "40" and Lee Lorimer. Four cars represented the Oaklands, and ten Oldsmobiles presented the various phases of that car. The total of the different makes of cars exhibited was forty-one.

The Commercial cars and trucks were represented by three makes, the Rapid, the American and the Knox. The electric division was represented by the Babcock and Waverley, the latter having at last headed an invasion of the Babcock in its home city.

HARTFORD DISTRIBUTORS OF THE PIERCE-ARROW AND STEVENS-DURYEA HAD WELL-ARRANGED EXHIBITS

ROCHESTER

ROCHESTER, N. Y., Feb. 14—Notwithstanding a bad snowstorm and general inclement weather, something over 5,000 people turned out on the opening night of the third annual show held by the Rochester Automobile Dealers' Association, packed Convention Hall and gave a start to the undertaking that augurs success. Eighty-five exhibitors crowd the basement, main floor and balcony of this spacious hall almost to the limit, and make a splendid showing.

From a spectacular point of view alone the show is a beauty. The color scheme is white and green, very much after the fashion of that held in the Grand Central Palace in New York City. The walls are adorned with suitable paintings illustrative of the development of the industry. The ceilings are draped with green and white bunting and electric lights, presenting a mild and pleasing general design. Palms and fresh cut flowers are to be found on every hand and the signs and space divisions are uniform throughout. The arrangements for handling the crowds are excellent, and notwithstanding the number of people who attended there was no delay either at the exits or the entrances.

In one respect at least Rochester has outdone all the other shows, even including the national shows. That is in respect to the music. Instead of having one band in the main hall to answer all purposes there are no less than two full military bands and an orchestra. The bands are on the two divisions of the main floor and the balcony and the orchestra is in the basement. The building is so arranged that they do not conflict.

The Aero Club of Rochester has furnished a large model monoplane which hangs conspicuously over the band stand in the main floor, and in the balcony and basement are to be found a number of motor boats and marine engines by way of variety.

Perhaps one of the most expensive exhibits is that of S. J. Macy & Company. That company is showing the identical Palmer-Singer exhibit, Dreadnought and all, that was shown at both New York and Chicago. This entailed some considerable expense and no little work, for the same cars were in Chicago last Saturday night. They were expressed and reached Rochester Monday just in time to be set in place. After this show they are to be shipped to Portland, Me.

The Sullivan Motor Car Company is showing for the first time the Sullivan light delivery wagon. This is a 16-horsepower, two-cylinder car that sells for $1,050.

EXHIBITION

Thomas J. Northway is showing a Ford T polished sectional chassis made in his own shop. Not being able to get one from the factory, Mr. Northway took down one of his cars, polished the chassis and then cut away the engine so as to show the moving and working parts.

Boughton & James are showing for the first time a solid metal non-skid armor that certainly looks as though it will do the things intended. It is cast in sections so as to fit around the tire and is held in place by longitudinal bolts and threads which when tightened hold it fast against the tire and prevent creeping. It is guaranteed against breaking or bending and is said to be absolutely skid-proof even on ice.

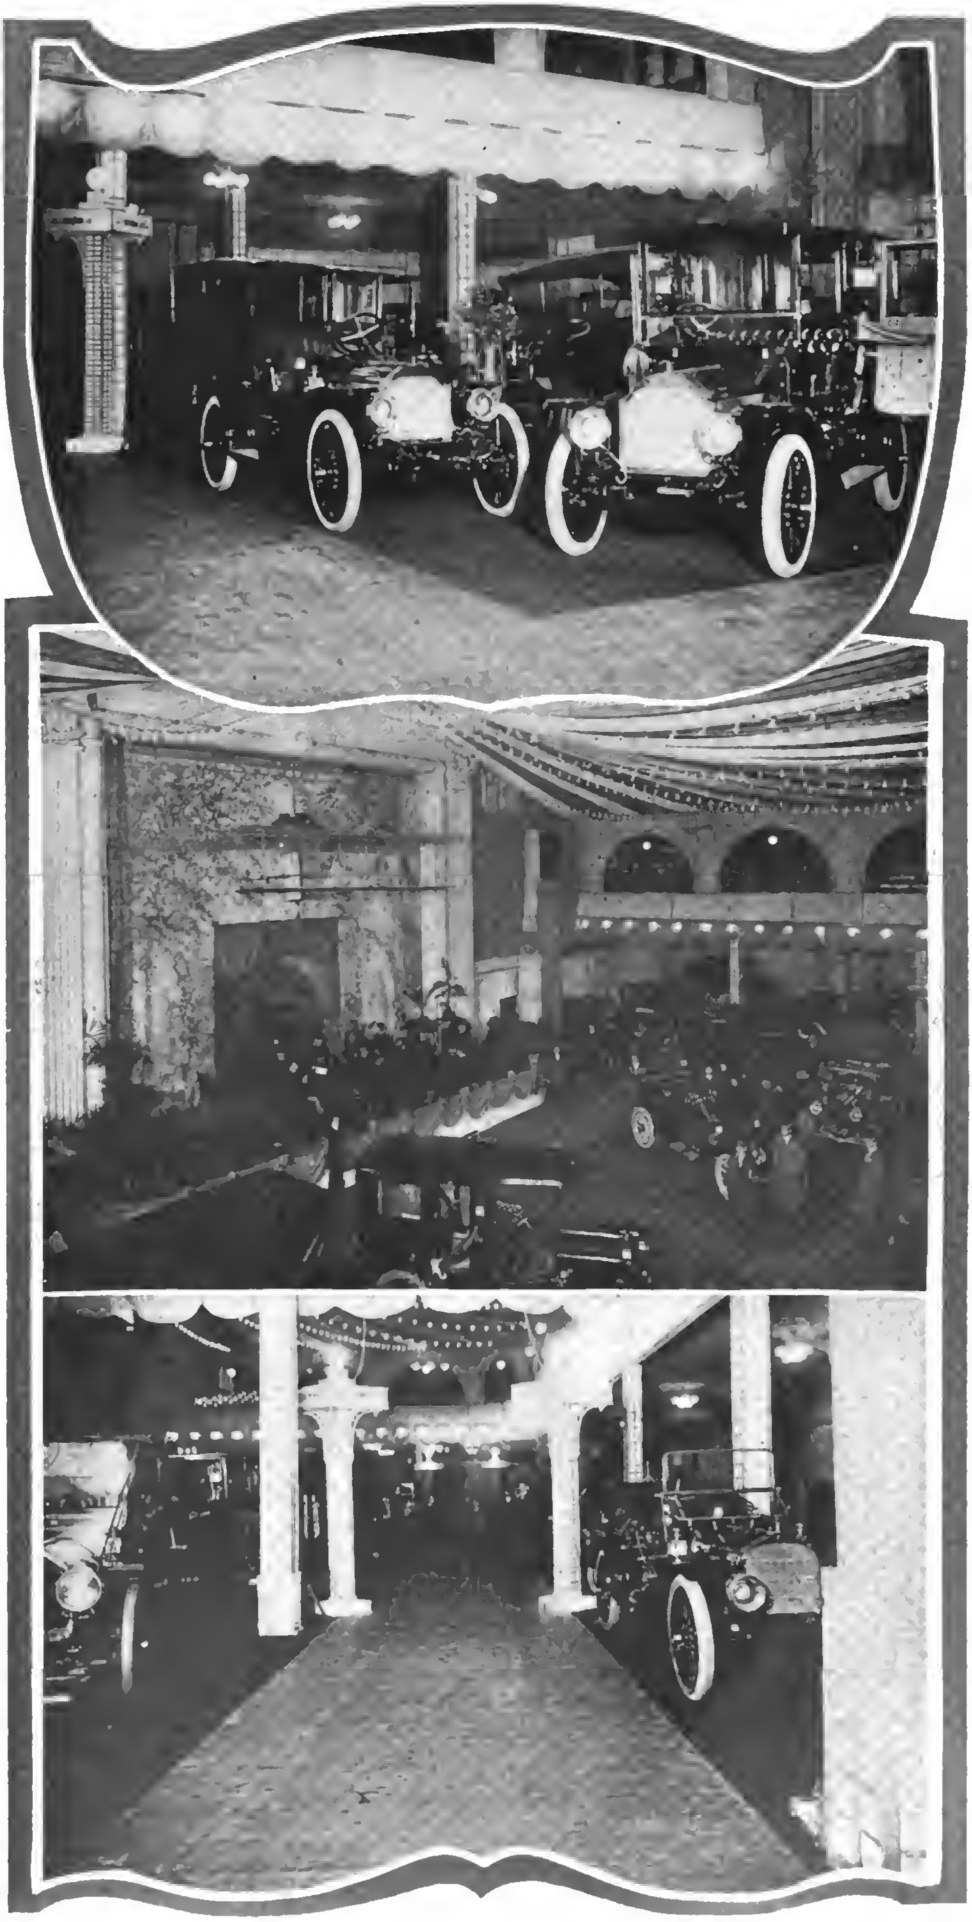
The only car of local make on exhibition is the Rochester Special, shown by C. P. Smith & Company. It is one of several built practically for the local trade. In size it is the largest in the place, being fitted with a Herschel-Spillman motor of six cylinders. 5 1-2 by 6 inches, rated at 75-horsepower. The tire equipment is 40-inch on all four wheels, and the other dimensions are in keeping. Mr. Smith is considering the building of a very large number of these cars this year.

At the conclusion of the first night's exhibit a meeting of the dealers' association was called, principally for the purpose of presenting William C. Barry, Jr., the president, with a token of esteem. in return for his efforts toward the success of the show. Mr. Barry, who is the Selden distributor in this section, has been both president and chairman of the executive board of the dealers' association for three years, and during that time has been most prominent for his devotion to its best interests.

Captain A. C. Simmons, the manager of the show, ruled the meeting. and with a neat speech delivered to Mr. Barry a silver-mounted pigskin suitcase, inscribed with the regards of the association. Mr. Barry responded briefly.

A concerted effort has been made by way of boosting and advertising throughout the neighborhood to reach 30,000 attendance for the week, and it looks as though this will be consummated. Thursday night will be society night at double admittance.

While the snow was welcome at the time of the recent Rochester-Syracuse endurance run, it was far from that to the demonstrators at the show. These were obliged to make their cars do their prettiest in order to make any kind of a showing against the heavy fall of snow.



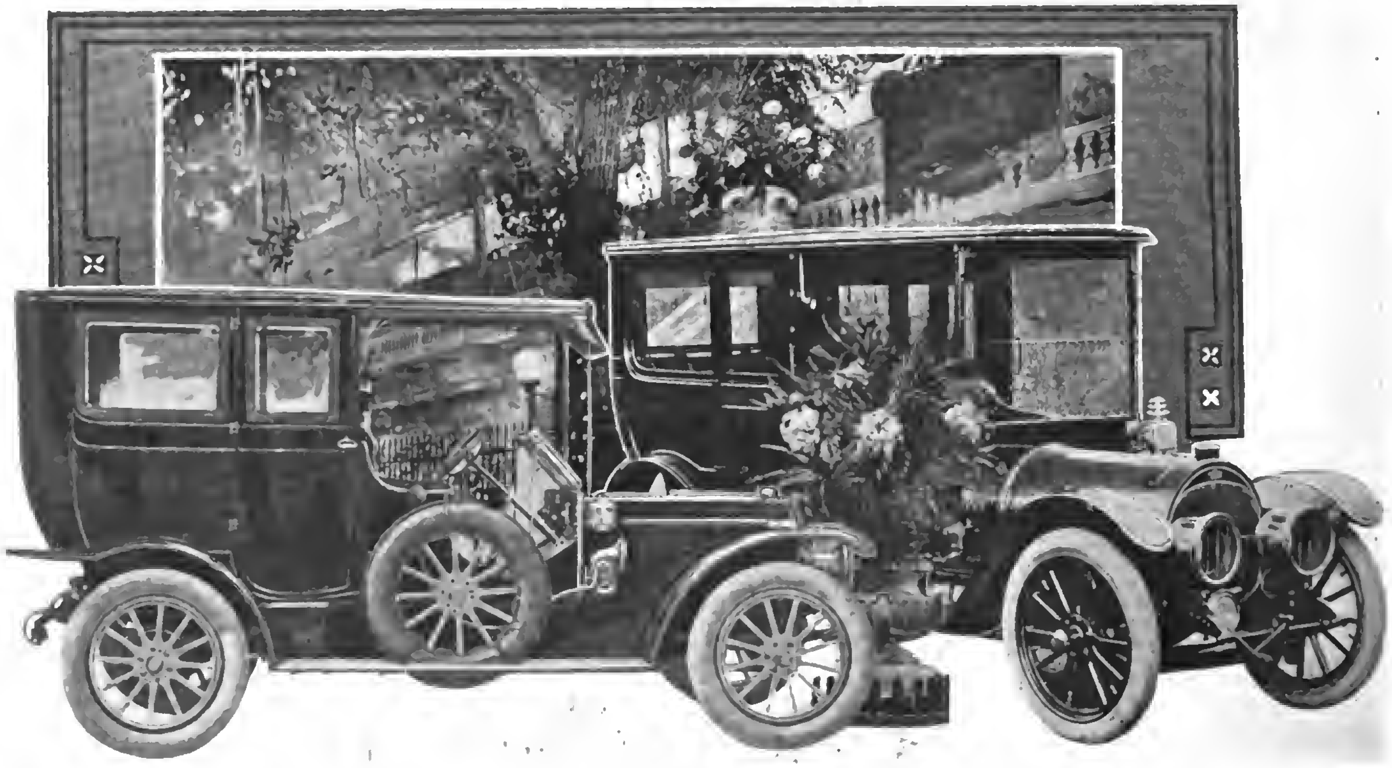
CHICAGO SHOW CLOSES WITH EXCEPTIONAL RECORD

CHICAGO, Feb. 14—The annual show of the National Association of Automobile Manufacturers came to a successful ending Saturday night, and, looking ahead a year, Manager Miles announced to-day that the affair would be repeated in 1911 in the same buildings, the Coliseum and the First Regiment Armory, despite reports that there are plans under way for the construction of a twelve-story building on Michigan avenue, between Twentieth and Twenty-first streets, which might be used for show purposes. Although cognizant of the plans for the erection of this gigantic structure and knowing that the promoters of the enterprise desire his support, Mr. Miles declares that he is not in on the deal and that he is well satisfied with the buildings which he now uses for his big show. No date for the 1911 exhibition has been set as yet, but it will probably take place in February, as it has done for several years past.

Any one who was at the show last week could not but remark at the big attendance and the vast amount of business that evidently was being done by the 267 exhibitors, and it was clearly apparent that the 1910 exhibition of the N.A.A.M. had a larger attendance than any of its predecessors and that more cars were sold, both wholesale and retail, than ever before. Indeed, the claim is made that the Chicago show excels both of the New York affairs put together in attendance and business, and this claim goes without contradiction on the part of manufacturers who showed at both Chicago and New York.

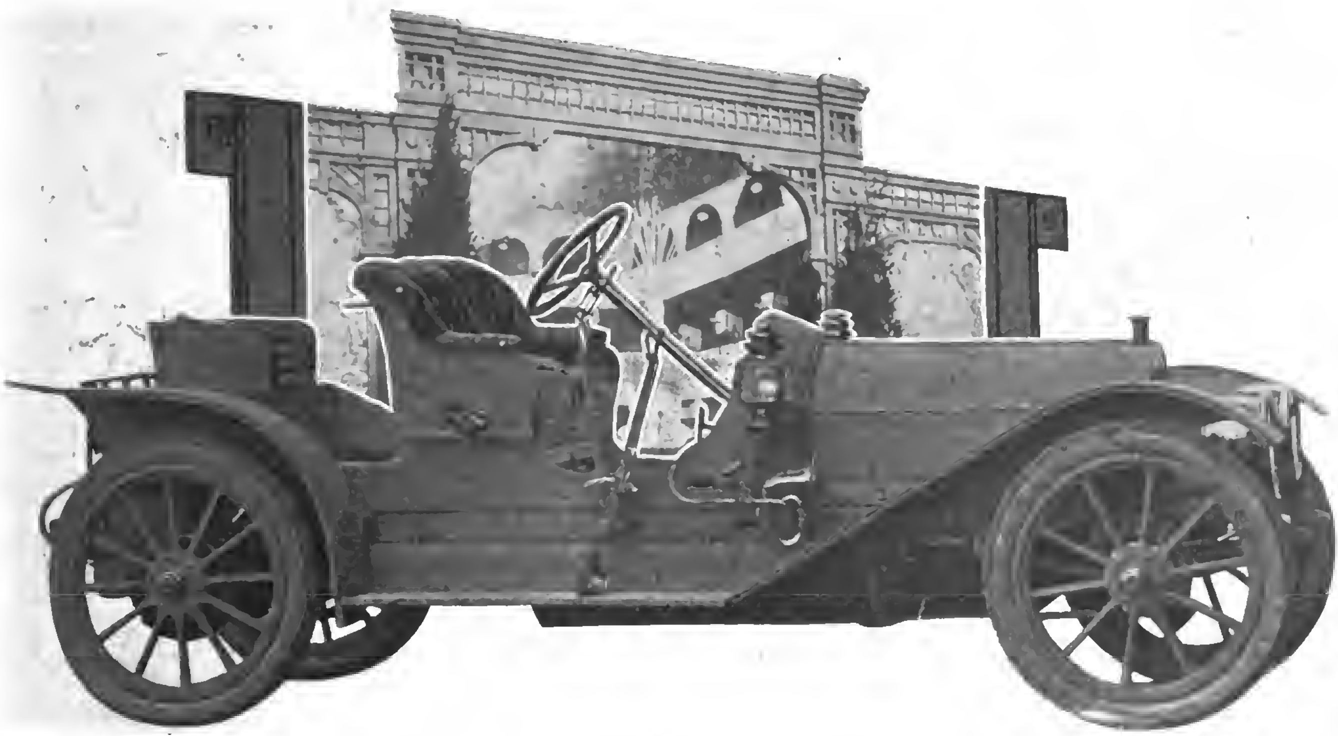
Actually, there were 140,000 paid admissions to the Chicago show for the seven days and nights which it ran, and the number of people who actually passed through the turnstile must have been at least 200,000. The records show that 2,924 exhibitors' buttons and 1,548 dealers' buttons were issued, which, if they were used each day, would add at least 32,000 to the 140,000 paid admissions; on top of this there was the paper of Saturday, the opening day, as well as complimentary tickets issued to the press. Of the 4,500 exhibitors and dealers on the list 75 per cent. came from out of town, and each one of them probably spent at least $50 during the week for his expenses. It is easy to see just what this meant to Chicago—$1,000,000 at the very least. The books show that dealers were here from Maine and Mexico; and some of the larger cities, like Denver, Kansas City, Milwaukee, Minneapolis and Indianapolis, sent large delegations of dealers.

Every one of the big car makers is loud in his declaration that Chicago is the best show of the year. During the week many new agencies were appointed in vacant territory, although it had been generally supposed that nearly every big concern had closed for the year. Besides this, the volume of retail business was so great in contrast to other years as to be most marked. Heretofore few retail sales were recorded, but this time many people actually attended the show and placed their orders, most of it being new business which had not been worked up before, and which, therefore, was unexpected. As to who did the biggest business at the show, there is considerable rivalry. There were several concerns—new ones—which placed many cars, but which hardly claim this was done because of the show, for they had been working through their agents before. For instance, Walter Githens, representing the Everitt in this territory, announces he took orders for 176 cars in his section.



Types of Limousines Which Combine Luxurious Bodies and High Power; on the Left Rambler, on the Right, Royal

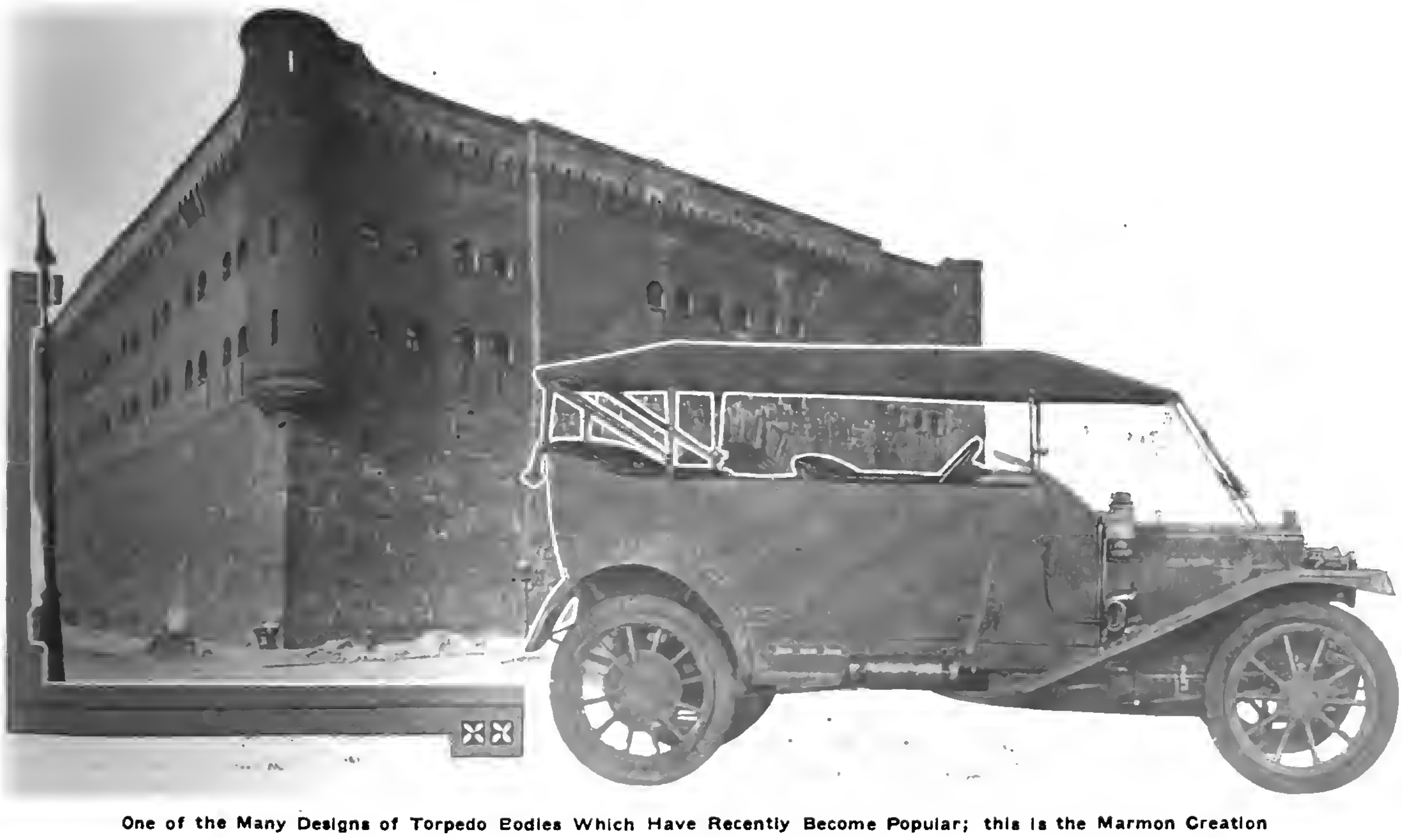
The Pierce-Arrow Company was handicapped somewhat by not having any 1910 cars for sale, business they did do at the shop being confined to 1911. There were few agents at the Pierce-Arrow booth during the week, but notwithstanding all this a fair business in 1911 stock was done. The Packard, which was shown by its local agent, confined itself to retail business, and reports many sales. The Knox Company did a big wholesale business, and the Oakland met with such a demand for its new 30-horsepower model that it was forced to stop taking wholesale orders for that type. Reo did a good business in both branches, and its attendance of agents from all parts of the country was surprisingly large. It reports dealers from Los Angeles, Denver, Omaha and Portland, Ore., and every



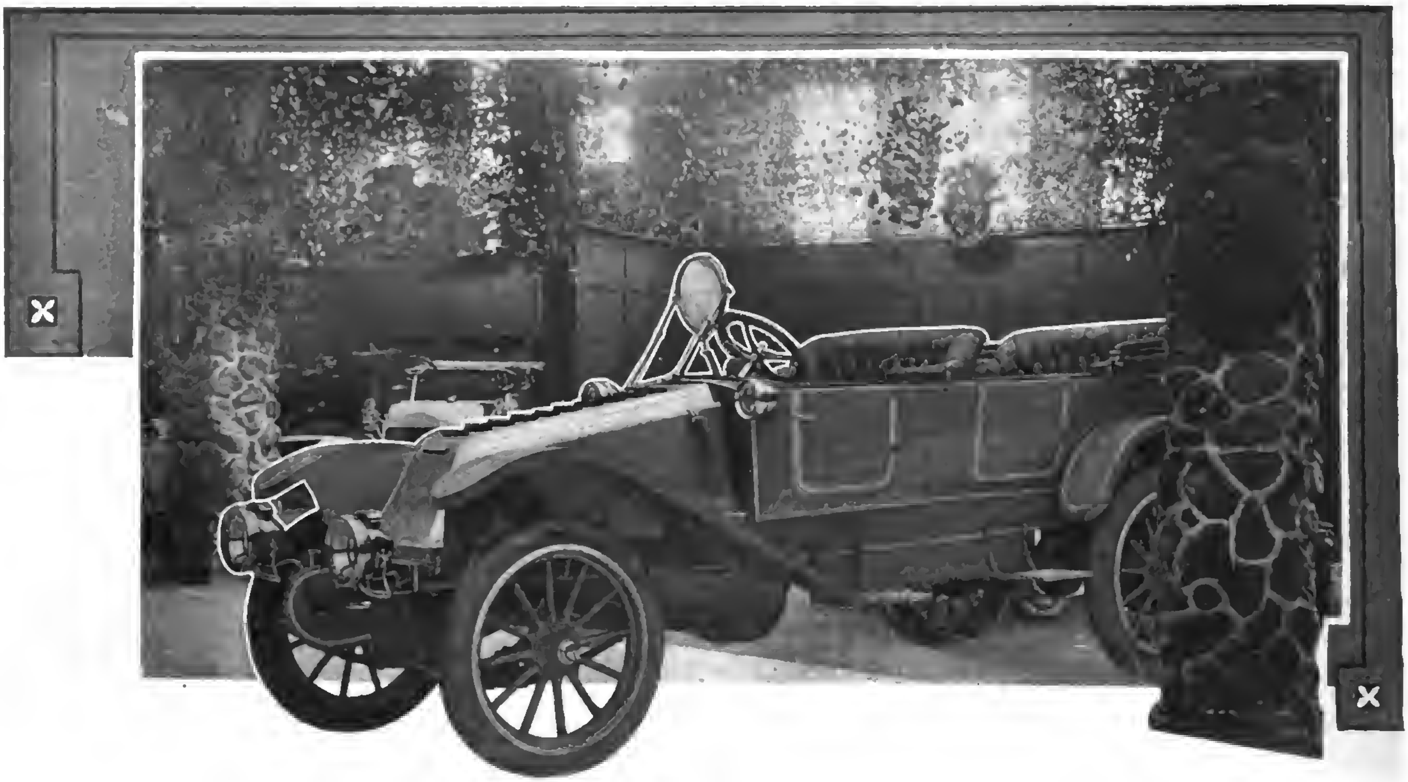
Latest Pierce Six-Cylinder 36-Horsepower Runabout, a Swift and Comfortable Car for Both Business and Pleasure

agent in Illinois was at the show. The foreign exhibitors did well, flattering reports having been received from the Fiat, Renault and Berliet, all of which did a considerable retail business during the show.

A building scheme was sprung yesterday, as referred to above, which promises the construction of a $2,000,000 building, to be devoted to automobile interests only. Those back of the scheme, which is being promoted by the Central Realty and Investment Company, are Lewis M. Stumer, Benjamin J. Rosenthal, Lewis Eckstein and Lee J. Lesser. It is proposed to erect the building on the east side of Michigan avenue, between Twentieth and Twenty-first streets, with a frontage of 307 feet and a depth of 170, the cost to be upward of $2,000,000. It is to be twelve stories high, with foundations and walls to carry six additional stories if found necessary. The twelfth floor will be a roof garden. On one floor will be a convention hall, and in the basement there will be Turkish baths, a swimming pool and a restaurant. It is proposed to fill the rest of the building with automobile dealers, using the eleventh floor for demonstrating purposes, which would make it unnecessary for the occupants of the building to go outside to give their customers a demonstration. However, the fact that some forty local concerns either



One of the Many Designs of Torpedo Bodies Which Have Recently Become Popular; this is the Marmon Creation



Franklin's Torpedo Body is Made with a Sloping Hood, Recalling Foreign Practice, Permitted by the New Motor

have built or are building new homes at the southern end of the row would seem to injure the chances of making this a success.

The show did not end without the Selden patent fight bobbing up, the latter part of the week being marked by a sharp retort from Henry Ford in answer to the warning advertisement of the Association of Licensed Automobile Manufacturers, and an attempt to form an organization of licensed dealers similar to the one started in New York recently. Ford's answer to the A.L.A.M. came out in the Friday morning papers. He made the claim that although the opinion of Judge Hough was filed on Sept. 15, 1909, no injunction has ever been entered against him in the case, nor has any decree been handed down. Ford also states that he still has two chances to fight, one the Court of Appeals and the other the Supreme Court. The delay is said to be due to legal difficulties in changing the name of the Electric Vehicle Company to the Columbia Motor Car Company.

Six-Cylinder American Napier Built in Boston Was One of the Most Conspicuous in the Six-Cylinder Field

NATIONAL LEGISLATIVE CONVENTION IN SESSION

WASHINGTON, D. C., Feb. 16—The New Willard Hotel is the scene of more than usual activity, even considering the many conventions and political gatherings which migrate to the heart of the nation in a year, due to the holding of the National Legislative Convention of the A. A. A., which is headquartered in the red room of the hotel. Numbered among the most prominent of our citizens at the time of the opening were: Vice-President Sherman, Senator Chauncey Depew of New York, the official delegates appointed by the Governors of 20 States and representatives from the 240 clubs which stud the country from Maine to California and from the Gulf to the north frontier.

The administrative staff of the A. A. A. are at the scene of activity in full force, Charles Thaddeus Terry, chairman of the legislative board, being in charge of the campaign, and supported by the immediate efforts of Powell Evans, chairman of the touring information board; S. M. Butler, chairman of the contest board, and George C. Diehl, chairman of the good roads board, is in the midst of the conflict with his coat off and sleeves rolled up. President Lewis R. Speare is making himself of the greatest utility to the cause, benefiting by the far-seeing counsel of vice-presidents R. T. Hooper, Frank N. Joyce and F. C. Donald.

Frederick H. Elliott, secretary of the A. A. A., is kept so much on the go in the performance of his manifold duties that it becomes practically impossible to obtain a comprehensive statement of the progress which is being made, or the results which should reasonably follow this concentrated and wise effort on the part of the A. A. A., to procure sane legislation which will be sufficiently broad in its scope to enable autoists to feel that they are within the confines of their own land when they cross the border of one State into the territory of another.

COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE

James R. Mann, of Illinois, chairman; Irving P. Wanger, of Pennsylvania; Frederick C. Stevens, of Minnesota; John J. Esch, of Wisconsin; Charles E. Townsend, of Michigan; James Kennedy, of Ohio; Joseph R. Knowland, of California; William P. Hubbard, of West Virginia; James M. Miller, of Kansas; William H. Stafford, of Wisconsin; William M. Calder, of New York; Charles G. Washburn, of Massachusetts; William C. Adamson, of Georgia; William Richardson, of Alabama; Charles L. Bartlett, of Georgia; Gordon Russell, of Texas; Thetus W. Sims, of Tennessee, and Andrew J. Peters, of Massachusetts, members. The clerk of the committee is F. A. Donnelly.

The program for to-day beginning at 10 A. M., was as follows:

"The Motor Vehicle, the Road and the Farmer"—Hon. Nahun J. Bachelder, New Hampshire, Master of the National Grange.

"The Federal Registration Bill"—Hon. Reuben C. Moon, Representative from Pennsylvania.

"Inter-State Intercourse by Motor Vehicle"—Col. Charles Clifton, President Association of Licensed Automobile Manufacturers.

"Motor Vehicle and the Roads"—Hon. Charles P. Allen, Chairman State Highway Commission of Colorado.

"Rights and Duties of Motor Vehicle Users and The Federal Bill"—Osborne I. Yellott, of Maryland.

"Traffic Rules"—William Phelps Eno, of Washington, D. C.

"Speed"—Addison Ely, Jr., of New Jersey.

The afternoon session, which will convene at 2 p. m., will include the following:

"Motor Vehicles and Their Regulation"—Major Richard Sylvester, Superintendent Metropolitan Police, District of Columbia, President International Police Association.

"Principal of Federal Bill, Approved by Bench and Bar"—Hon. Neal Brown, State Senator for Wisconsin.

"The Federal Bill"—Frank G. Webb, ex-President Long Island Automobile Club, Brooklyn.

"The Federal Bill"—S. Boyer Davis, Secretary Automobile Club of Philadelphia.

"Road Improvements in Georgia"—Frank C. Battey, President Savannah Automobile Club.

"Inter-State Roads and Inter-State Laws"—George S. Walker, of Wyoming.

"The Federal Bill—Personal Experiences in Touring"—Claud E. Miller, District of Columbia.

The real hearing before the Congressional Committee will take place on Thursday, February 17. The attitude of the delegates is bounded by the path of wisdom, and the many angles of this important situation are being handled by the foremost advocates of good roads, good ethics, and uniform laws, among which Logan W. Page, Director of the Bureau of Good Roads of the United States Department of Agriculture, is a prominent figure. Walter C. Schutz, of Connecticut, in his address, attracted most favorable notice, and said: "Automobile laws should be based on reasonableness instead of on prejudice." Col. Wm. D. Schier, of Boston, member of the Massachusetts Highway Commission, laid great stress on the necessity of licensing the operators of cars, with power to revoke such license for drunkenness, or the high disregard of the rights of others.

UNITED STATES MOTOR CO. ORGANIZING

This $16,000,000 organization, which was projected with a view to bringing together certain of the older and well-known companies, was reported as including the Maxwell-Briscoe interests and the Columbia Automobile Company, which report was subsequently verified, but details were withheld. Benjamin Briscoe, in a special interview in relation to this matter, authorized THE AUTOMOBILE to announce the fact that the permanent organization is sufficiently under way to bring definite results at a meeting which is imminent, and so far it is safe to say that the board of directors will be headed by Benjamin Briscoe and J. D. Maxwell. Of course, everybody knows Benjamin Briscoe as the president and general manager of the Maxwell-Briscoe Motor Company, and J. D. Maxwell as vice-president, general superintendent and designer of the same company. Mr. Briscoe, in his interview, states most emphatically that any statements other than the above will be without authority, and out of tune with the real situation. Nothing more can happen until the balance of the board of directors is chosen.

"TRUE BLUE" IS DETROIT'S LATEST

DETROIT, Feb. 14—The True Blue Motor Company is the latest entrant in the ranks of Detroit's automobile manufacturers. It is capitalized at $100,000, and will bring out a pleasure car to sell at $1,300, the first of the series being almost ready for the road. Among those interested in the concern are Wallace E. Brown, president of the Michigan Gas Mantle Company; Maurice Wolf, secretary and treasurer of the same company, and Edmund H. Coombs, of the Coombs-Gilmour Company, distributor of the Mitchell car in Detroit.

E-M-F-STUDEBAKER QUARREL SUBSIDING

The report to the effect that negotiations were entered into with a view to the settlement of the squabble into which these companies entered, was denied by the E-M-F Company in total, at the same time the whole situation presents a less turbulent tone, and it is now the general expectation that some wise solution will be arrived at in the near course of events.

LOOKS LIKE PACKARD-KNIGHT CONTROVERSY

KNIGHT GIVES HIS VERSION OF PENDING CONFLICT

LEGAL BATTLE MAY DELAY LICENSES

An interview in Motor Age of February 10 with a representative of the Packard Motor Car Company stated that it owns basic patents on sleeve-valve engines for the United States, and that the Knight engine is an infringement of Patent No. 12,991, re-issued to Sidney A. Reeve on July 13, 1909. In justice to Knight and Kilbourne I cannot permit it to pass unnoticed.

For a proper understanding of what has occurred, a brief history of the Knight engine, and its success, is essential.

The formal announcement of the adoption of the Knight engine by the Daimler Motor Company of England was made in September, 1908. Within 60 days after this announcement a number of leading automobile manufacturers of the United States had representatives in England to investigate the merits of the Knight engine. One of these representatives was the chief engineer of the Packard company. Through the kindness of the Daimler company Mr. Knight was permitted to take him through its plant and show him every process in the manufacture and testing of Knight-Daimler engines. A sample engine was shipped to the Packard company early in January, 1909, its chief engineer having returned to the United States in December, 1908. Particular attention is directed to the significant fact that, according to the certified copy of the Reeve re-issued patent, Reeve, on February 9, 1909, within less than two months after the return of the Packard engineer from England, and within less than one month after the receipt of the Knight engine, made affidavit to an application for a re-issue of his patent No. 880,824, of March 3, 1908. This must be taken to mean that the Packard engineers were impressed sufficiently to induce action.

Descriptions of the Knight engine have been published. In a word it consists of two telescoped sleeves, both having ports, and each receiving a definite valving motion from an eccentric properly timed according to the four-cycle principle and operated from the crankshaft. Both sleeves slide within the main cylinder which has a fixed head projecting down into the inner sleeve and carrying the spark plug. This head closes both the intake and exhaust ports of that sleeve. The piston performs its usual working stroke entirely within the inner sleeve. During the compression and explosion strokes, the inner sleeve is hermetically closed above by the fixed head and below by the piston, so that the charge is fully compressed without loss, and when the explosion occurs its full force is exerted directly against the piston in a perfectly cylindrical combustion chamber having neither side chambers nor crevices to detract from the force of the explosion or to catch accumulations of carbon, these and divers other advantages must be taken note of.

The Reeve device is described as a steam engine of the double-acting horizontal type. Referring to Fig. 1, the piston 6 works in a sliding cylinder 5 arranged in a casing 1, which constitutes the steam chest or "head chamber." This sliding cylinder is not operated by an eccentric or other positive means, like the Knight inner sleeve, but is caused to slide endwise by the friction of the piston, so that when the piston starts to move in one direction, the sleeve will slide therewith and cause its exhaust port 70 in one end or the other to register with one of the exhaust ports 10 in the casing of steam chest to permit the steam to escape from the forward side of the advancing piston. In the outer ends of this sliding cylinder 5, however, Reeve places two piston valves 15, which are adapted to close the inlet ports 120 of the sliding cylinder when a spring 119 behind each piston valve forces it inward and the sliding cylinder 5 is forced towards it by the friction of the piston as the piston moves in that direction. The pressure for moving the piston is exerted between the piston valve 15 and the piston, and during the working and exhaust strokes the piston valve is held from moving outward by a latch device, which is supposed to let go at the proper time during the return stroke of the piston to permit the steam that has been compressed between the piston and the piston valve to force the piston valve outward against the spring and cause the piston valve to slide out from under and again open the inlet port in the sliding cylinder 5.

Reeve shows two forms of his device, one of which is constructed as above described. The other is the same, excepting that he has supplied the sliding cylinder 5 with an auxiliary valve 121 at each end for the common purpose of co-operating with the piston valve 15 in cutting off the cylinder admission more economically than could be done by means of the piston valve alone. This auxiliary cut-off valve is found in the steam engine art in various forms, *i.e.* as piston valve, flat slide valve, ring valve and sleeve. Reeve has chosen the ring form, which he places around each of the protruding ends of the sliding cylinder 5, and which he says he operates from the crankshaft by an eccentric in the usual way, although he does not show the eccentric or operating means.

The combination of elements which constitute the sleeve valve inter-

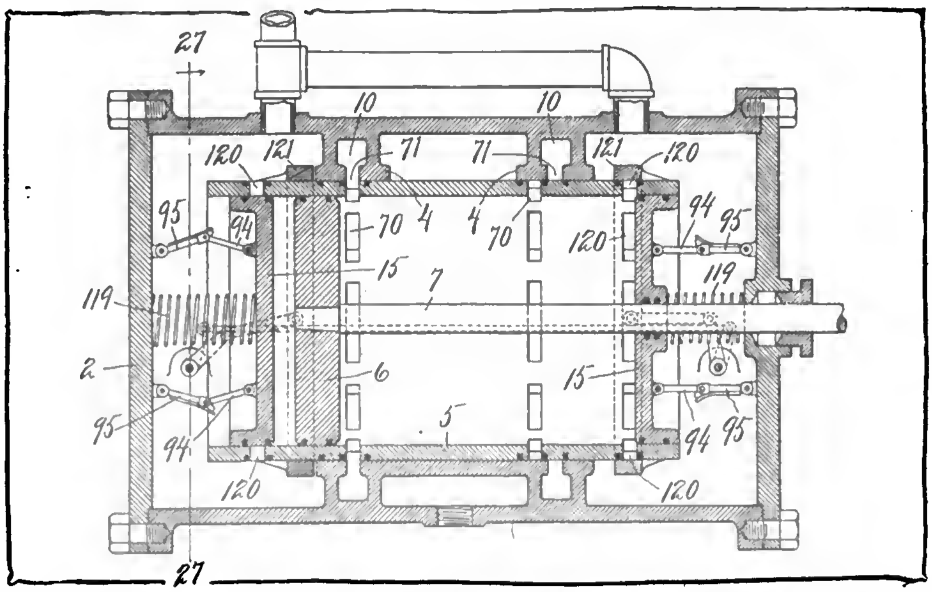


Fig. 1—Reeves valve mechanism as shown by drawings for re-issued patent 12,991, in which the Packard Motor Car Company is interested. Although this is not applied to a standard automobile motor, the principles are said to be the same.

nal explosion motor were common in the steam engine art years before Reeve's invention, as shown in Fig. 2 by the United States patent of Uren, No. 303,344, issued August 12, 1884, to have the main piston B^2 slide in a sliding cylinder C contained within a casing or main cylinder A and having ports adapted to register with ports in the casing for controlling the cylinder admission and exhaust, the internal sliding cylinder being moved by the friction of the piston, as in the Reeve patent, and it was also old in hydraulic motors, as shown in Fig. 3 of United States patent No. 352,797 of Baldwin, November 15, 1886, to provide the internal sliding cylinder K with an auxiliary cut-off valve 1, 2, 3, 4 encircling each end in the form of a ring and controlling the admission ports, i, i^1 in the sliding cylinder K. In this Baldwin patent these cut-off valves are connected together so as to move in unison by a cylinder W surrounding the internal cylinder K, and both of these cylinders are contained within a main cylinder or casing G having an inlet port Z. The cut-off valves 1, 2, 3, 4 receive definite motion from a valve operating rod N, just as in the Reeve patent. The piston in this Baldwin patent is shown at J, and while it is the main piston, it also serves as two piston valves for controlling the exhaust ports M, M^1 in the internal sliding cylinder.

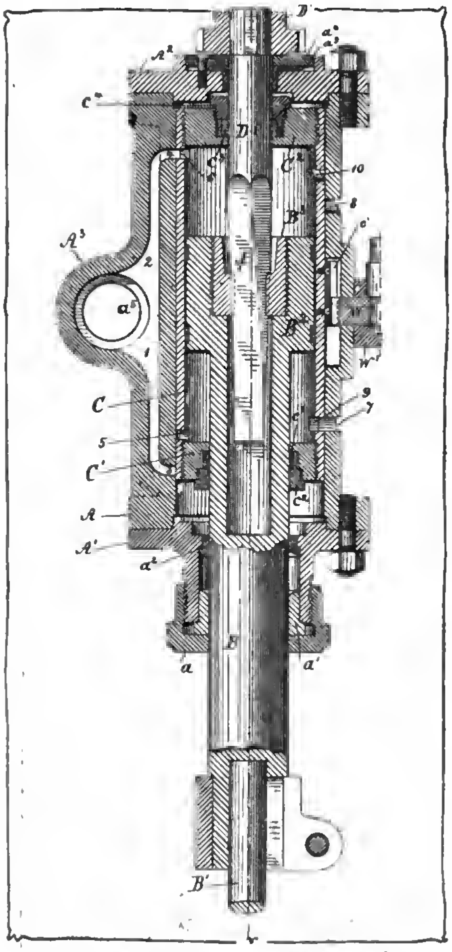

Fig. 2—Uren patent, No. 303,344, which is claimed by Knight interests to conflict with the Reeves patent illustrated above.

The present owners of the Reeve reissue saw and fully appreciated the fact that the Reeve original patent claimed a structure in which no eccentric was employed, and consequently must have claimed the form of the Reeve engine which does not contain the outside auxiliary or cut-off valve. Therefore, when applying for the reissue patent they omitted from the specification the statement of advantages above quoted so as to be able to direct the claims of the reissue to the form of the engine having the outside cut-off valve operated by an eccentric. Consequently, the reissue is for a different invention from that which the patentee intended to cover by the original. The United States Circuit Court at Chicago in the case of Chicago Railway Equipment Co. v. Perry Sidebearing Co., 170 Fed. Rep. 968, has recently settled these questions in a very exhaustive opinion, and this decision has been sustained by the United States Circuit Court of Appeals, and enforced against the reissue even to greater limits. In this decision, the Court said:

Thus it is sought by the language of the reissue claims to broaden the limited claims of the original patent into claims covering the whole field * * *. It seeks to bring within the monopoly of its patent sidebearings not apparently in mind at the time of filing the original application * * *. It can hardly be claimed that the original patent was not a complete device. It was operative just as completely as that of the reissue patent. For all that Wands was seeking, it was in itself a finished sidebearing arrangement. Later he thought he could just as well claim the resilient centering device and make it apply to every friction sidebearing which is centered by a spring. Undoubtedly he made the mistake of not claiming the larger invention, if it be such in his first application; but this is not the mistake the statute and the courts have in mind. (Authorizing the grant of re-issue patents.)

In Campbell v. James, 104 U. S. 356, U. S. Supreme Court said:

When a patent fully and clearly without ambiguity or obscurity describes and claims a specific invention complete in itself so that it cannot be said to be inoperative or invalid by reason of a defective or insufficient specification, a reissue cannot be had for the purpose of expanding and generalizing the claim * * *.

In a further attempt to show that a re-issue must be for the same invention without having its scope or bearing broadened in any particular other rulings may be cited.

The real force of decision is clearly apparent, since Reeve intended by his original patent to cover a steam engine in which there would be no eccentric for operating the valves, whereas in his reissue patent it became necessary to claim the eccentric operated valve in order to establish a color of right to the Knight invention.

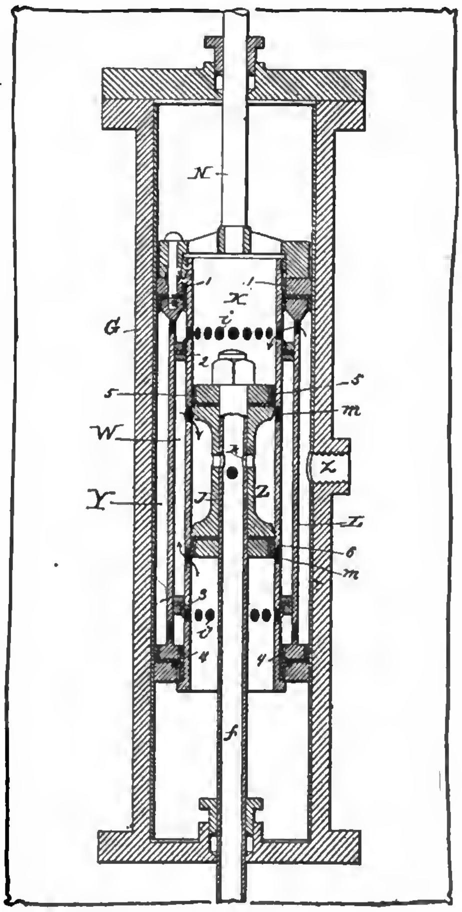

Fig. 3—Baldwin patent, No. 352,797, another valve mechanism resembling that of Reeves and claimed to conflict with it.

In Huber v. Nelson, 148 U. S. 270, the United States Supreme Court held the reissue invalid because it left out one of the elements of the original claims.

In Chicago Railway Equipment Co. v. Perry Co., above referred to, the United States Circuit Court at Chicago, in speaking of the effort of the reissue patentee to enlarge his claim by omitting an element originally described as important in explanation of the situation said:

These two things are vital elements of that patent. Now it is sought by re-issue to drop out the distinctive feature of the patent as described in the claims and substitute another element.

This comment is pertinent because Reeve seeks by his reissue to drop out the statement contained in the original, making essential the form of his engine in which no eccentric is employed for operating the valves, and then to specifically cover this eccentric form by his reissue claims.

The United States Circuit Court of Appeals in New York in the case of Carpenter Co. v. Searle, 60 Fed. Rep. 82, laid down the rule that unless the invention of the re-issue is described as the invention in the original, and that the patentee intended to secure it as his invention in the original, the re-issue is invalid. Other rulings may be cited in support.

(Signed) F. E. Conas,
Attorney for Knight & Kilbourne.

NEW IDEA—POPULAR CAR VOTING CONTEST TROPHY

ANNUAL MIDWINTER NEW YORK TO BOSTON RUN

PERLMAN TROPHY WILL BE COMPETED FOR

THIS contest has been arranged in compliance with the instructions of L. H. Perlman, who desires to open the season of 1910 with a contest that will reflect credit on the trade and invite favorable criticism from the public. The trophy furnished by him at a cost of $500 is to be awarded to the car receiving the greater number of votes cast at the points hereinafter named.

Arrangements have been made with the Hotel Astor to have its dining room open for breakfast at 5 a. m. Saturday morning, March 5, 1910, and the contestants will get away at 6.

Under no circumstances are the speed ordinances to be violated at any time during the day. There are no speed requirements and it is specifically understood and agreed that none will be indulged in, consequently no one will be permitted to pass the pace-making car. Any entrant who passes the pace-making car will be disqualified and must withdraw from the contest.

Each contestant will be provided with a set of flags bearing the name of the car, in large distinct letters that the public may easily discern.

Each car will receive when arriving on the starting line the official ballot box. When reaching a voting station or control the representative of the car must place this box in a conspicuous place, but under no circumstance must he allow it out of his possession.

The controls or voting stations are at the following points: Bridgeport, New Haven, Hartford, Springfield, Worcester and Boston.

Cars must follow the official route and comply with the speed regulations which will not allow of passing the pacemaker.

A contestant must not stay more than 30 minutes in the control or the vicinity. There is no restriction as to the number of passengers, or the method of soliciting votes.

A daily paper in each city which has been selected as a station, will for one week, beginning Monday, publish in its columns the official ballot, none other will be recognized. The daily printed ballot will carry the names of the cars entered up to the time of going to press.

When there is more than one car entered of the same make, each will receive a ballot box, but the votes will be counted collectively.

The polls will be under the jurisdiction of the show committee at Boston who will appoint tellers. Polls will close at 9 p. m. Saturday night. If a contestant has not reached Boston by that hour he will be considered out of the contest.

Each checking or voting station will be under the direction of the referee of that city and his appointment will be made by the paper which is running the ballot. The moment that the show committee announce the winner the award will be made. As a method of determining the relative popularity of the various cars entered, the run should be productive of interesting results. At any rate, it is a distinct novelty among contests.

The violation of any of these rules and conditions particularly as relates to speed will be judged by the referee. An official representative of the contest board of the American Automobile Association will accompany the tour.

Entry blanks for this contest may be had by applying to T. F. Moore, manager of the contest, whose address is 91 West 103d street, New York City.

Notable among the many affairs of the sort which accompanied the Chicago show was the dinner given by F. C. Roble, president of the Excelsior Supply Company, of Chicago, to the salesmen and department heads of his organization. The dinner was held Thursday, February 3, in the clubrooms of the Chicago Automobile Club, of which Mr. Roble is a member. Besides the officers and staff of the home company, practically all of the traveling representatives were present, only two or three being too far distant to attend

NATIONAL LEGISLATIVE CONVENTION AT WASHINGTON

WILL DISCUSS NEEDS OF UNIFORM AUTOMOBILE LAWS

NATIONAL REGISTRATION BILL GIVEN HEARING TUESDAY

STATESMEN, legislators, and prominent automobilists from all parts of the country will assemble in Washington this week for the three days' session of the National Legislative Convention, which will be held in New Willard Hotel on Tuesday, Wednesday and Thursday, February 15, 16 and 17. This convention has been organized and will be conducted under the auspices of the American Automobile Association, and its primal objects will be the securing through national legislation of the Federal Automobile Registration Bill, and at the same time a wider recognition by the various State officials who have been appointed by their respective Governors, of the benefits of the uniform State automobile law.

Coming within a month of the big convention in Washington of the National Civic Federation, which was devoted to the highly important subject of uniform laws, this legislative convention, which will be solely devoted to the needs for uniform and more equable automobile legislation, will be, perhaps, the greatest public demonstration of the sort ever seen in this country towards securing favorable legislation for an industry which has suddenly assumed gigantic proportions in the commercial life of this country, while vitally affecting the comfort and convenience of thousands of individuals.

Invitations extended on behalf of Charles Thaddeus Terry, chairman of the Legislative Board of the A. A. A. to the Governors of all the states in the Union, have met with the most favorable response. Official representatives have been appointed by the Governors of nearly twenty States, in many cases these delegates including the Secretaries of State and the State Highway Commissioners; thereby showing the increasing interest in the subject of automobile legislation and the apparent willingness of the various States to enact harmonious laws. From the automobile clubs throughout the country, as was naturally expected, the response has been highly satisfactory, and the delegates named from scores of clubs, as well as many state automobile associations, include most of the prominent motorists who are well known as earnest workers for the best interests of automobiling.

Secretary Frederick H. Elliott, of the A. A. A., arrived in Washington on Thursday to open headquarters in the New Willard Hotel.

President Lewis R. Speare, Chairman Charles Thaddeus Terry, A. G. Batchelder, chairman of the Executive Committee, and other officials will follow, and by Monday the reception of the visiting delegates will be well under way. The national officials will be aided in their arrangements and reception of delegates by the Automobile Club of Washington, which has appointed a committee of twenty-five to act as the Washington reception committee. President H. Chadwick Hunter, who has taken an active part in working for the success of this convention, will act as chairman of this committee of twenty-five, and his assistants will be John K. Heyl, Elliott P. Hough, W. S. Duvall, Lester D. Moore, Louis A. Dent, William D. West, J. Hamilton Smith, R. B. Caverly, J. H. Falconer, D. J. Dunigan, Fulton R. Gordon, Harrington Mills, A. Ward Evans, Franz Kopp, W. A. Copenhaver, Charles W. Bender, John F. Maury, H. C. Chandlee, W. W. Chiswell, O. J. De Moll, William Muehleisen, Jr., F. H. Edmonds, A. L. Cline.

The opening day of the convention on Tuesday will be mainly devoted to the subject of uniform State legislation in automobile matters, at which time particular attention will be given in the various addresses and discussions to the necessity of enacting uniform laws by the different States in the Union. This is a subject that the national automobile association has been working for during the past half dozen years, and its efforts have been crowned with success in several states. The salient features of the uniform State motor vehicle bill as drafted by Mr. Terry about four years ago have already been adopted by several States, and the benefits that have accrued thereby not only to motorists but to all the users of the highway have been such as to recommend a similar system of uniformity in other States.

President Speare, of the American Automobile Association, will open the convention at ten o'clock Tuesday morning, and he will be followed by Senator Chauncey M. Depew, of New York, who will make the address of welcome. Chairman Charles Thaddeus Terry, of the Legislative Board of the A. A. A, as well as of the National Legislative Convention, will then outline the purposes of the convention, explaining in detail the merits of the uniform State motor vehicle bill, as well as the benefits to be derived by the National Federal Registration Bill. Among the speakers who will follow him discussing different phases of the uniform legislative question will be Senator Rayner, of Maryland; Senator Beveridge, of Indiana; Congressman Dalzell, of Pennsylvania; Secretary of State Rogers, of Connecticut, and Secretary of State Martindale, of Michigan. Among the prominent speakers in the afternoon session will be Logan Waller Page, Director of United States Office of Public Roads; James H. MacDonald, Highway Commissioner of Connecticut; Secretary of State Thompson, of Ohio, and Secretary of State Bailey, of Vermont.

The second day's session of the convention on Wednesday will be chiefly devoted to the Federal Registration Bill, which will be outlined in the discussion by Congressman Moon, of Pennsylvania; President Charles Clifton, of the Association of Licensed Automobile Manufacturers; Hon. Henry B. F. Macfarland, President of the Board of Commissioners of the District of Columbia; Hon. Neal Brown, State Senator of Wisconsin; Frank G. Webb, of the Long Island Automobile Club, and S. Boyer Davis, of the Automobile Club of Philadelphia. Other addresses will be made by William Phelps Eno on "Traffic Rules"; Hon. Charles P. Allen, Highway Commissioner of Colorado, on the "Motor Vehicle and Roads," and Addison Ely, Jr., of New Jersey on "Speed and Its Regulations." Ex-Governor Bachelder, of New Hampshire, will speak on "The Motor Vehicle, the Roads and the Farmer."

To the automobilists of the country who have been working for and are deeply interested in this vital subject of uniformity, the great day of the convention will be on Thursday, the closing day, when the hearing will be held on the Federal Registration Automobile Bill. This bill is already before Congress, having been introduced by Congressman Cocks, of New York, a year ago, and has been referred to the Committee on Interstate and Foreign Commerce, before which the hearing will be held in the Capitol.

The complete list of delegates to date, is:

Delegates Appointed by State Governors

Colorado—Charles P. Allen, Chairman Colorado State Highway Commission; appointed by Governor Shafroth.

Connecticut—Secretary of State Matthew H. Rogers and Arthur Ffoot; appointed by Governor Weeks.

Indiana—Carl G. Fisher and Clarence A. Kenyon, of Indianapolis; appointed by Governor Marshall.

Michigan—Secretary of State Frederick C. Martindale; appointed by Governor Warner.

Maryland—Osborne I. Yellott, of Baltimore; appointed by Governor Crothers.

Vermont—Secretary of State Guy W. Bailey; appointed by Governor Prouty.

Wisconsin—James T. Drought, of Milwaukee, and Capt. William Mitchell Lewis, of Racine; appointed by Governor Davidson.

Wyoming—J. E. Mershon, Rock Springs; Fred. Fisher, Fayette; Elmer Lovejoy, Laramee; George S. Walker, Cheyenne; appointed by Governor Brooks.

Florida—Edward Holder, Jack Camp, J. D. Robertson and R. L. Anderson; appointed by Governor Gilchrist.

Oregon—Dr. C. B. Brown, Portland; appointed by Governor Benson.

Kentucky—George H. Wilson; appointed by Governor Willson.

Delaware—F. Allen Hilles, Wilmington; appointed by Governor Pennewill.

Delegates from A. A. A. Clubs

Colorado—Charles P. Allen, Denver Motor Club.

Florida—T. Edward Bryan and Capt. C. S. Washington, Tampa Automobile Club.

Georgia—John J. Woodside, J. D. Rhodes, R. J. Guinn, Atlanta Automobile Association; F. C. Battey, Savannah Automobile Club.

Iowa—Dr. Harry Pierson Engle, Newton Motor Car Club.

Massachusetts—A. E. Lerche, president, and S. L. Haynes, Automobile Club of Springfield; John P. Coghlin, president, and F. A. Easton, Worcester Automobile Club; W. H. Chase, president, Wachusetts Automobile Club.

Minnesota—Dr. C. H. Kohler, Minnesota State Automobile Association.

New York—S. C. Tallman, president; Hon. Sereno E. Payne, Charles L. Sheldon, Arthur J. Blauvelt, Automobile Club of Auburn; H. A. Meldrum, president, and Bert Van Tuyle, secretary, New York State Automobile Association; Allen C. Alderman, president, Frank G. Webb and Dr. William P. Richardson, Long Island Automobile Club; H. G. Strong, president, Bert Van Tuyle and W. W. Dake, Automobile Club of Rochester; Dr. E. G. Cox, president, and Henry Martin, Albany Automobile Club; William H. Mendel, president, and J. J. Sinnott, Mt. Vernon Automobile Club.

New Jersey—Frank B. Stratford, J. H. Edwards, Dr. Henry Spence, J. V. Z. Anthony, Automobile Club of Hudson County; Dr. J. N. Faulkner, vice-president North Jersey Automobile Club; J. H. Wood, R. A. Greene, C. H. Bissell, New Jersey Automobile and Motor Club.

Ohio—Dr. A. B. Heyl, secretary, Ohio State Automobile Association; C. J. Forbes, Jr., secretary, Cleveland Automobile Club.

Pennsylvania—B. D. Wright, Edward J. Kent, Edward Kneeland and Paul C. Wolff, secretary, Automobile Club of Pittsburg; Hon. William M. Brown, ex-Lieutenant Governor, Hugh Graham and Jere Bauman, Automobile Club of Lawrence County; S. Boyer Davis, secretary, Howard Longstreth and Harrison K. Caner, Automobile Club of Philadelphia; G. Douglas Bartlett, G. Hilton Gantert, Quaker City Motor Club; I. D. Wood, J. E. Mitchell and A. H. Tomlinson, Automobile Club of Delaware County; E. Foster Heller, Wilkes-Barre Automobile Club.

Vermont—W. W. Brown, president, Allen M. Fletcher, Charles C. Warren, Addison Ely, Jr., James Boutwell and S. S. Ballard, secretary, Automobile Club of Vermont.

Virginia—H. H. Trice, Tidewater Automobile Club; J. H. Marsteller, Roanoke Automobile Association; C. B. Richardson, Richmond Automobile Club; William E. Barrett, Peninsula Automobile Club; M. C. Watts, Valley Motor Club.

Wyoming—George S. Walker, Cheyenne Motor Club.

Wisconsin—Hon. Neal Brown and James T. Drought, secretary, Wisconsin State Automobile Association.

Illinois—Dr. W. W. Williams, Quincy Automobile Club; Fred W. Blockl, Chicago Automobile Club.

Connecticut—John N. Brooks, Secretary, Connecticut Automobile Association; Walter S. Schutz, Automobile Club of Hartford.

Kentucky—George H. Wilson, Louisville Automobile Club.

West Virginia—C. N. Brisco, secretary, Monongahela Automobile Club; T. A. Westmeyer, Ohio Valley Automobile Club and State Association; W. T. Carter, Parkersburg Automobile Club; Dr. R. H. Pepper, Huntington Automobile Club.

PREMIER MAKES ENTRY IN FLAG-TO-FLAG RACE

THE first entry for the approaching run from Denver to Mexico City for the Wahlgreen trophy was made recently by President H. O. Smith of the Premier Motor Manufacturing Company. The entry blank was filled out and delivered to George A. Wahlgreen, of Denver under whose direction the contest will be held. On May 2 it is expected that the tourists will start from Denver and the first car to be sent away will be a Premier driven by Ray McNamara.

Details of the event are being arranged by Mr. Wahlgreen, who has received assurances from so many prominent licensed automobile manufacturers of their support that there seems no doubt but that this interesting contest, which was postponed from last Fall, will actually be held. The Premier interests have felt that this grueling test will be another opportunity to show additional evidences of the ability of their cars and and additional chance to repeat the successes in recent Glidden and other hard contests. About three weeks will be necessary for the machines to make the trip, and in that space of time they will cross part of Colorado, all of New Mexico, part of Texas and run through nine States of the Republic of Mexico. The distance is about 2,400 miles, which is nearly as long as the 1909 Glidden Tour, and much longer than the route for the next A. A. A. event.

MILESTONES FOR THE AUTOMOBILIST

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main street.

Feb. 14-19........Hartford, Conn., Foot Guard Armory, Third Annual Show, Hartford Automobile Dealers' Association.

Feb. 14-19........St. Louis, First Regiment Armory, Fourth Annual Automobile Show, St. Louis Automobile Manufacturers' and Dealers' Association, Robert E. Lee, Manager, 1629 Washington avenue.

Feb. 14-19........Rochester, N. Y., Convention Hall. Third Annual Show, Rochester Automobile Dealers' Association. Captain C. A. Simmons, Manager.

Feb. 15-19....... Washington, D. C., American Automobile Association's National Legislative Convention.

Feb. 17-19........Grand Rapids, Mich., First Annual Automobile Show, Grand Rapids Automobile Club.

Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Los Angeles, Cal., Hamburger Building, First Annual Show, Licensed Dealers of Los Angeles.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South street.

Feb. 19-26........Cleveland, Central Armory, Annual Automobile Show under auspices of the Cleveland Automobile Show Company. H. M. Adams, Secretary.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-26........Baltimore, Second Annual Automobile Show, Auto Club of Maryland, Fifth Regiment Armory.

Feb. 21-26........Portland, Me., Auditorium, Fifth Annual Automobile Show. F. M. Prescott, Manager.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Mgr.

Feb. 28-Mar. 5....Omaha, Neb., Auditorium, Automobile Show, Omaha and Council Bluffs Automobile Dealers.

Feb. 28-Mar. 5....Kansas City, Convention Hall, Fourth Annual Automobile Show, Automobile Dealers' Ass'n.

Mar. 5-12........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park square.

Mar. 5-12........Cleveland, Central Armory, Cleveland Automobile Club Eighth Annual Show.

Mar. 5-12........Des Moines, Ia., Coliseum, First Annual Automobile Show, Des Moines Automobile Dealers' Ass'n.

Mar. 7-12........Albany, N. Y., Armory, Automobile Show.

Mar. 12-19........Syracuse, N. Y., State Armory, Automobile Show. Syracuse Automobile Dealers' Association.

Mar. 17-19........Louisville, Ky., Armory, Louisville Automobile Dealers' Association Annual Automobile Show.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsman's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2....Pittsburg, Pa., Dusquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2....Montreal, Coliseum, Motor and Sportsmen's Show. E. M. Wilcox, Manager.

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), Mey, 1902, Dealer and Repairmau (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Good roads, if they mean anything at all, represent the key to general prosperity. The automobile, no matter what else of good may be ascribed to it, is the greatest influence for advancement of all the devices which men of the last century reduced from a state of chaos, or placed in the hands of workers.

If there are a few minor defects of the automobile, as it is met with on the road, even if a few "road hogs" make things unpleasant on occasions, the fact still remains that the demand for good roads is the surest indication of the intrinsic value of the automobile industry, taking it as a whole. It is useless to try to dam up an ocean; pigmy minds may not be able to project thought for a distance beyond a pug nose, but the industry will go on just the same, and the roads, which are, in all truth, the other half, will be designed and constructed.

That the roads, if they are to be good, will have to be designed, seems to be too true to be disregarded any longer, and when the truth is told it is likely to lay bare the entire absence of designing, considering some of the roads which seem to pound out rather too soon to allow of realizing a fair return on the cost. It is easy enough to say that this high depreciation is due to automobiles, and it may be true that automobile traffic is too much for certain kinds of roads.

Before automobiles came into vogue there was trouble enough with these same roads, and every State had its laws which regulated the width of tires in proportion to the load which weighed them down, and is here mentioned merely to indicate that it is easy enough to forget that the trouble now complained of is the same trouble that obtained for many years, and long before the automobile was in use at all.

Just as it is possible to go back to a time when roads were so bad that no one ever thought of complaining about them, it is now possible to foresee a time when they will be so thoroughly good that there will be no reasonable ground for complaint. For the present it is a matter of education; it is necessary to remove the last vestige of complaint which is so prone to overshadow all else, and this can be accomplished by teaching drivers of automobiles to respect the rights of others, and requesting others to reciprocate.

The automobile shows which are now being held at important centers all over the country are working out the problem of the automobile to a far greater extent than show managers contrived. The shows interest an increasing circle of citizens from year to year, and in view of the merit of the automobile as the servant of the whole people, all that is necessary is to have them come and see —they do come to the shows, and, what is equally to the point, they do see.

Purchasers, when they decry a practice, which to them seems out of step with the spirit of the times, are, more likely than not, on the second lap of a fallacy. In the manufacture of anything, be it a peacemaker for an infant in the shape of a sweetened rag on the end of a string, to the house on wheels which contents the soldier of fortune who seeks adventure in Spain, demand comes first; supply is the answer.

If a maker is trying to foster upon the supporters of the automobile industry, something out of the cloth called by the name shoddy, it must be true that the maker is either without any experience at all, or, experience has shown to him that there are enough shoddy purchasers on the horizon to support the industry. If the maker is mistaken in his notion, if there is no demand for his wares, the receiver will follow him like misfortune after its mate, and the law of supply and demand will be satisfied.

That makers do anticipate demand is not to be denied, and that this idea is a safe one in a sense, is proven; if a certain automobile, after much experience, presents stable characteristics, and the demand for it is constant, it is good practice to examine the sales books, ascertain the strength of demand and take advantage of lowering costs which come from manufacturing on a basis of a steady rate of output.

The antithesis of constant demand and manufacture for stock account is present when purchasers of shoddy characteristics follow the bent of normal inclination and encourage the manufacture of equipment which is not under the restraint of the conventions; the bait being greed; the hope being that something will be had for nothing; the end, like in shoddy cloth, leaves a mesh of entangled rope ends—the part which deceives, like the varnish over the unfaithful automobile, falls to the ground; it may not respond to the expectations of the purchaser, but it cannot escape the influence of gravity.

MOTOR RATINGS DISCUSSED

POWER provides a never-failing source of discussion for the automobilist. No other term in his vocabulary is so misused or misunderstood, or has so many interpretations, and at the same time it is a subject of vital interest, inasmuch as it affects his comfort, his pride or his bank account. It is that quality which makes the difference between passing that other car on the road, and being forced to take its dust; or between climbing a hill in good form, and being obliged to get out and push. Naturally, when he invests a thousand, or several thousand dollars in a car, he wants all the power that his money can buy.

Power, as a technical term, has a very definite meaning. It is defined as the rate of doing work. Work, in turn, is the product of a force and the distance it moves. Thus power is force, times distance, divided by time. It is expressed in units implying these three quantities, as pounds per foot per minute, or kilograms per meter per second. A horsepower is 33,000 foot-pounds per minute; that is, a power which can lift 33,000 pounds one foot in one minute, or one pound 33,000 feet in one minute, or one pound one foot in 1-550 second.

In a gasoline motor power is developed by the burning, and consequent expansion, of the gaseous mixture. The expansion results in a force exerted on the piston head; the travel of the piston on its stroke gives the distance, and the number of strokes per minute adds the time factor. Given the pressure in pounds, the stroke in inches or feet, and the number of strokes or revolutions per minute, the horsepower developed in a gasoline motor cylinder can be readily figured. Although the last two quantities are easy enough to obtain, the first, unfortunately, cannot be had without the use of delicate and costly instruments.

Nevertheless, these instruments, known as indicators or manographs, form part of the equipment of every modern testing laboratory, and valuable results are obtained from their use. On the indicator or manograph card the pressure at every point in the cycle, or in a succession of cycles, is graphically indicated. The pressure on the expansion stroke shows the force which is doing useful work. This pressure is a variable, high immediately following the explosion, and falling off as the piston nears the bottom of its stroke. To make it available for calculation it must be averaged; the average figure, known as the mean effective pressure, is the quantity which, taken with the stroke and the revolutions per minute, will give the power developed in the cylinders, or indicated horsepower.

However, not all of the power developed in the cylinders is delivered at the flywheel. Friction takes a share, in the thrust of the pistons on the cylinder wall, the necessary tightness of the piston rings, the bearings of the connecting rods and the crankshaft journals. More power is lost in driving the valves, the pump, magneto and oiling system. The amount of these losses varies with the construction of the motor; here care and accuracy of workmanship make themselves felt. For motors in good running order the loss is a fairly constant percentage.

To determine the power actually delivered by the motor numerous methods are in use; all depend on the absorption and incidental measurement of the power, as by a friction brake, an electric generator, a water pump or a fan. As the earliest and best known of these the friction, or Prony brake, method may be described. Like all the others, it depends on the definition of power as force times distance, divided by time. The application is quite generally familiar; a brake band or shoe applied to the flywheel, and prevented from rotating with the flywheel by weights on the end of a lever arm. The weight, or the length of the arm, is adjusted until the weight is in equilibrium, tending neither to rotate with the flywheel, or to drop under the force of gravity. The weight then gives the force, the length of the arm the distance, and the number of revolutions per minute the time factor, necessary for calculating the horsepower.

Brake horsepower, as the figure thus obtained is called, is usually regarded as the best standard for judging the ability of an automobile. However, in order to determine the power actually available for driving the vehicle, it is necessary to gauge the power delivered at the rear wheels; for there are losses in the transmission from the flywheel to the drivers, just as there are in the transmission from the cylinders to the flywheel. Horsepower at the rear wheels may be measured by a Prony brake, or by the other forms of testing devices mentioned, just as power at the flywheel may be measured.

No form of brake horsepower lends itself to a method of rating; obviously the only way to measure brake horsepower is to perform the actual test. To get a rating by which the power can be estimated without an actual test, or even before the motor is built, it is necessary therefore to go back to the less desirable form, indicated horsepower. The quantities needed for the calculation are here the area of the piston head on which the pressure acts, easily obtainable from the cylinder bore; the

INDICATED HORSEPOWER OF MOTORS

$$\text{Power} = \frac{\text{Force x Distance}}{\text{Time}}$$

$$\text{HP} = \frac{\text{Force (lbs.) x Distance (ft.) per min.}}{33{,}000}$$

Force = M.E.P. (lbs. per sq. in.) x Area of piston (sq. in.) x No. cyls.

Distance per minute = Stroke (ft.) x ½ Revolutions per minute

$$\text{Indicated HP} = \frac{\text{P x A x N x S x R}}{66{,}000}$$

STROKE, REV. AND PISTON SPEED

	R.P.M.						
Stroke.	900	1000	1100	1200	1300	1400	1500
3½....	525	583	642	700	758	817	875
3¾....	562	625	687	750	812	875	937

4½....	675	750	825	900	975	1050	1125
4¾....	712	792	871	950	1029	1108	1187
5	750	833	917	1000	1083	1167	1250
5¼....	787	875	962	1050	1137	1225	1312
5½....	825	917	1008	1100	1192	1283	1375
5¾....	862	958	1054	1150	1245	1341	1436
6	900	1000	1100	1200	1300	1400	1500

number of cylinders; the stroke of the pistons; the speed in revolutions per minute at which the power is to be figured, and the mean effective pressure. The last is the only one which offers any difficulty.

Of course it is just as impossible to predict exactly what will be the mean effective pressure of any motor, as it is to predict what weight its flywheel will balance on a five-foot lever arm; but it is possible to take an average figure for the mean effective pressure which will be a reasonable expectation, given detail design and workmanship up to the standard. For this purpose the mean effective pressures of a number of well-known motors have been worked out from their known performances, and are given herewith for reference. It will be noted that the powers used in deriving these figures are all brake horsepowers, and that the mechanical losses between the piston heads and the flywheel have been ignored. The actual pressures must in all cases be sufficiently higher than those given to balance these mechanical losses. Therefore, if the expectations of the power to be developed by a suppositious motor are based on these figures, the expectations will be in terms of brake horsepower rather than indicated horsepower, which is exactly what is wanted.

The figures quoted for mean effective pressure range, it will be observed, from 70 to 100 pounds per square inch. The latter is the pressure attained by the English Daimler motor with the Knight sliding-sleeve valve system, and is one of the highest ever reached on a stock motor. The examples show, further, that the

BRAKE HORSEPOWER OF MOTORS

$$\text{Power} = \frac{\text{Force x Distance}}{\text{Time}}$$

$$\text{Horsepower} = \frac{\text{Force (lbs.) x Distance (ft.) per min.}}{33{,}000}$$

Force = Weight (lbs.) applied on lever arm
Distance per minute = 2π Length (ft.) of lever arm x Revolutions per minute

$$\text{Brake HP} = \frac{2\pi \text{ L x R x W}}{33{,}000}$$

mean effective pressure for any motor is by no means constant. If it were, the power curve of that motor would be a straight line, showing variations in power exactly proportional to those in speed. As a matter of fact, the pressure falls off with an increase of speed over a certain point, determined, of course, by the peculiarities of the individual motor. Figures on the Daimler-Knight motor show a pressure of 100 pounds at 1,172 revolutions, whereas at 1,500 revolutions the pressure is but 93.9 pounds, this in spite of the admitted fact that the Knight valves are better adapted to high speeds than poppet valves.

It must not hastily be assumed that the excellence of a motor is shown by its mean effective pressure; the designer's intentions should be considered. A high-pressure motor is naturally subject to more severe strains and stresses than a low-pressure one, and, other things equal, may be considered shorter lived. The question of flexibility also enters largely. To secure high compression, and consequent high pressure at high speed, the initial compression may be made so great that the motor will not throttle down. This is often seen in racing motors.

In devising a rating formula from the formula given for indicated horsepower, it is first of all necessary to assume arbitrarily a figure for the mean effective pressure, as this is the most dangerous variable quantity to be reckoned with. Most formulas take 70 pounds as the average; a figure conservative, but not unjust. Secondly, the speed must be assumed. A formula

DERIVATION OF A. L. A. M. FORMULA

$$\text{Indicated HP} = \frac{\text{P x A x N x S x R}}{66{,}000}$$

Assume P (Mean Effective Pressure) = 70.
Assume piston speed is a constant = 1,000 ft. per min.;
then 2 S x R = 1,000, and S x R = 500

$$\text{Ind. HP} = \frac{70 \text{ x } \tfrac{1}{4}\pi \text{ D}^2 \text{ x N x } 500}{66{,}000} = \frac{\text{D}^2 \text{ x N}}{2.4}$$

$$\text{A. L. A. M. HP.} = \frac{\text{D}^2 \text{ x N}}{2.5}$$, for convenience in calculation.

often favored is horsepower = one-tenth the piston displacement, in cubic inches. For a four-cylinder 5 by 6 motor, in which the piston displacement is 471.2 cubic inches, this gives a rating of 47.1 horsepower. A moment's calculation will show that this formula is based on the assumption of 70 pounds as the pressure, and 1,131 revolutions per minute as the speed, or of other figures in proportion.

The formula in widest use is that known in this country as the A. L. A. M., and in England as the R. A. C. This differs from the preceding in that the second quantity assumed is not revolutions per minute, but piston speed. If, as before, 70 pounds is taken as the pressure, the piston speed will be close to 1,000 feet per minute. Corresponding speeds in revolutions, for motors of a given stroke, may be obtained from the table. In the table of pressures one figure for each motor is at the speed at which the motor should develop its A. L. A. M. horsepower; the justice of the assumptions may be deduced from these figures.

The value of any horsepower formula depends, therefore, on the accuracy with which its assumptions fit the motor in question. The A. L. A. M. formula obviously does not fit the Daimler-Knight motor, which develops 58-horsepower under the conditions which by formula should give 38. For the great majority of motors it comes close to the facts; a few may even be flattered. In view of the popularity of testing laboratories, the usefulness or desirability of formulas seems limited. Under any circumstances, the only real way of determining the horsepower of a motor is by a brake test. More and more popular among the manufacturers is the practice of stating in their catalogs the actual brake horsepower developed by their motors at a given speed; unless the speed is stated, however, such figures are valueless. An authenticated test is always worth any number of formulas to the automobile buyer.

DYNAMOMETER METHODS EMPLOYED

MAKERS of automobiles, when they desire to determine definitely the power which may be taken from the motors after they are produced, resort to the use of a dynamometer of some sort, and, in the absence of just a little practice, are likely to adopt the most simple form of Prony brake, primarily on account of its low first cost, then in view of the small amount of time required in rigging it up, and finally with the hope that it will suffice for the purpose.

Experience with this simple form of measuring device leads to the conclusion that, while it may be suitable for emergency use and will serve a certain crude purpose, it is not, by any means, an instrument of precision such as may be relied upon in these days, considering the exacting requirements of automobile motor testing, especially if account is taken of the high rotative speed of automobile motors.

In testing an automobile motor for power and flexibility, there are conditions as follows to be satisfied:

(A) The motor must be run in; the bearings must be brought to a state of well being, and the parts must be limbered up.

(B) A test to determine maximum load must be run, and in order to realize an advantage from this effort, it is necessary to prolong the run for a sufficient time to determine if the motor will perform continuously at the maximum load.

(C) The next point is to ascertain, by a run of sufficient duration at low speed, if the motor will heat up; if the radiator is of adequate capacity, and if the flywheel is heavy enough to afford all the advantage that can be induced in this way.

(D) Flexibility is the next point to be fixed upon; a motor may perform well at the two limits of speed and be absolutely lame at some intermediate speed. The best way to ascertain if this desired condition is present will be to run a test at equidistant points in the speed range, and plot a curve to show torque for speed.

There is no form of simple Prony brake that will allow of tests such as these, and, unless these tests can be made, it is doubtful if there is any use of going to the trouble and cost of rigging up to make any test at all. A practical man, in the absence of a Prony brake, will be able to tune up a motor so well that he will be able to judge its performance in a general way, and he will get along just as well without the crude device above mentioned as he will with it.

In many automobile plants where motors are made in quantities, the run-in test is regarded as a necessity, and it is a simple expedient to attach a fan to the crankshaft, in place of a clutch, and, if the fan is properly devised, it will limit the speed of the motor to that which should obtain in actual service when the motor is doing its accustomed work. The fan requires no attention, it offers a constant resistance so long as the speed of the motor is maintained constant, and, if speed changes do creep in, they will indicate that some adjustment is necessary, either to the carbureter or the sparking equipment, but there will be no damage done even if the adjustments are not made. This form of dynamometer is economical, it takes up almost no added space, and it is, in first cost, at the bottom of the list. In some instances the fan dynamometer has been fitted out with a tachometer, by means of which the speed is counted, and by previously calibrating the fan, the power delivered may be noted by ascertaining the speed and comparing it with a chart of power for speed as determined by a previous calibration.

The fan dynamometer may be used to note the effect of maximum load, provided the speed of the motor is maintained at the point which will cause the fan to load the motor, and the endurance of the motor under conditions of maximum load may be noted. For the minimum load, it is not practicable to employ the fan unless it is so designed that the blades may be shifted to offer just the amount of resistance to rotation which will afford the minimum load under conditions involving the best fuel mixture.

It is at this point that the fan falls short of the best requirement; it depends, for result, upon speed. When it is desired to ascertain the range of power of a motor at a given speed, which range is then brought about by changing the quantity and character of the mixture, the fan dynamometer fails to serve the purpose.

TESTING DEMANDS USE OF FLEXIBLE DYNAMOMETER

It is this condition of flexibility which must be given the greater amount of attention, although it is of the greatest importance to ascertain if the parts, as crankshaft, connecting rod, piston pin, and bearings, will sustain under conditions of maximum load and when the speed changes violently. To be able to determine flexibility, it is but a matter of employing a suitable dynamometer, of which there are types to be had as follows:

(A) Dynamo electric machine, to be driven by the motor to be tested; the output to be absorbed by a suitable rheostat.

(B) Electro-dynamometer, which differs from the dynamo test to the extent that the torque is exerted on a lever-arm which is secured to the field (frame) of the dynamo, and by measuring the pull in pounds, considering the length of the lever, the power of the motor to be tested may be determined.

(C) Hydro-dynamometer, which is made up of a disc, or a

EFFICIENCY OF DYNAMOS

Dynamos or motors, as used in testing automobile motors, must be calibrated. The losses must be determined:

(A) Bearing, friction, and windage losses.

(B) Loss in brushes due to friction.

(C) Loss due to hysteresis and eddy currents.

(D) Loss due to foucault currents.

(E) Loss due to armature resistance at the several loads.

(F) In separately excited machines the field (winding) losses do not count.

(G) Since it takes approximately five hours to heat a dynamo or motor to its maximum under full load, it follows that any testing done by means of such a machine, to be accurate, must allow for temperature increase or the test must be conducted after the dynamo or motor is heated up to the maximum.

(H) Measuring instruments, as volt, ampere and watt meters, must be calibrated at frequent intervals, and always before and after an important test. A double set of instruments will add materially to the accuracy of all such tests made.

FORMULA OF PRONY BRAKE

$$H.P. = \frac{2\pi R S P}{33{,}000} = \text{brake horsepower.}$$

$$R = \frac{H.P. \times 33{,}000}{2\pi S P} = \text{radius of arm in feet.}$$

$$S = \frac{H.P. \times 33{,}000}{2\pi R P} = \text{speed in r.p.m.}$$

$$P = \frac{H.P. \times 33{,}000}{2\pi R S} = \text{pull on lever.}$$

plurality of discs which are rotated at high speed in a water bath within a suitable housing.

(D) Balanced electric system of testing, which comprises a plurality of separately excited electric machines, they being capable of operating as dynamos or motors, at the will of the operator. Control is by use of suitable field rheostats, by means of which the fields of the machines are altered as to strength at will; if the field is weakened the machine will deliver a lower voltage, and it will then be driven, as a motor, by the mate to it, which will run as a dynamo.

In a plant where a large number of automobile motors have to be tested in, the balanced electric system has many advantages. There may be any number of sets of these machines; all that is required to satisfy the conditions is to have the machines in pairs, referring to the electrical relation; in this way one machine (of each pair) is driven as a dynamo, which furnishes current to the other, which, as a motor, drives the motor to be run in. The dynamo, of course, loads the motor, and it furnishes the power, which is electrically transmitted, to drive the second motor, which is being run-in during this period of time. Since the conditions may be reversed at will, the operator simply manipulates the change-over switch as conditions indicate the necessity.

Electrical instruments, placed on a convenient board together with all necessary switches, tell of the power which is delivered by the first motor of a pair in driving the dynamo, and the electrical energy which is converted to mechanical work, tells of the power requirement in running in the second motor of the pair; there may be any number of sets of this equipment in a test room, and a single operator can handle possibly 20 sets. This method eliminates rheostats, lamp-banks and other troublesome features, and it has the virtue of being economical as well as flexible.

There is still one other possibility; if the automobile motors to be tested are connected to pumps (of the centrifugal type), and the pumps in turn are connected, by piping, to a reservoir, the power required to pump the water to the reservoir may be adjusted to equal the ability of the motor to be tested, and the work done in the process may be turned to good account—the water stored by this process in the reservoir may be used for fire and other purposes around the plant. This method of testing has the virtue of being both stable and flexible, and the only point which would have to be taken into account as being a possible obstacle, is, the water pumped would have to be turned to good account or the work done by the motors being tested would be wasted just as it is now in the other methods of testing.

It will be understood that the motor-testing question has other angles besides the one which is being considered here; investigation of the internal conditions, requiring the use of a manograph, is one phase of the subject. Brake tests, however, are made after the motor is finished, and when the designer has concluded all other investigations.

When the brake test is concluded, it is then proper to go into the question of the relation of the motor to the car; this involves the gear ratio, speed changes, power required to propel the automobile, hill-climbing ability, and performance when the going is bad. Very many satisfactory automobiles may have been investigated only to find that the motor was not capable of driving them as fast as they would have to go to satisfy the gear ratios established.

The remedy, in a case of this sort, lies in increasing the gear ratio; this will allow the motor to speed up to a higher point considering the speed of the automobile, and, as might be expected, will have the effect of lowering the speed on the level, but the ability of the motor will be in better keeping with the requirement when the automobile is making a hill or is down in the mud and the demand is maximum.

If a dynamometer test permits of determining the torque of the motor at its different speeds, it does not help to determine the torque requirement as indicated by the automobile on the road, and it is this condition which indicates that a certain amount of power is needed at each speed; the motor must be capable of delivering this power at the speed as fixed by the gear ratio.

The character of motor to use depends upon the character of the service demanded; it is not the same in touring work as it is in racing, and flexibility of the motor is what is wanted in touring, just as in racing maximum speed is the main requirement. It is especially difficult to so design a motor that it will give the last "drop" of power at a very high speed, and, at the same time, realize flexibility to a degree.

Flexibility comes when the motor is especially designed for just this property, and, when characteristics of motors are being discussed, it is necessary to consider the work which is to be performed when the merit of the motor is being fixed upon.

The probabilities are that the most flexible motor will be the one with a high mean effective pressure relative to the maximum explosive pressure, and especially if the torque is represented by a straight line throughout the range of speed as it is fixed by the gear ratio and the ability of the motor, considering the power required by the car.

COMPUTING LOSSES IN CALIBRATION.

$$\text{Efficiency} = \frac{\text{output in watts}}{\text{input in watts}}$$

$$= \frac{\text{output}}{\text{output} + \text{core loss} + \text{copper loss} + \text{friction} + \text{etc.}}$$

Characteristics of the losses:

(A) The core loss, which is made up of the hysteresis loss and eddy current loss remains constant at a constant potential.

(B) The copper loss changes as follows:

$$W = I^2 R; \quad \frac{E^2}{R}; \text{ measured in watts.}$$

Considering the machine as a motor:

(C) $$I = \frac{E - e}{R} = \text{current in amp. input.}$$

(D) $$W = E \; \frac{E - e}{R}$$

(E) $$w = e \; \frac{E - e}{R}$$

RELATION OF POWER TO SPEED

CONCEALED within the problem or the interrelation of power, weight and speed are a number of smaller, lesser, but nevertheless important minor matters. These, although slight, have enough of a bearing upon the main problem to necessitate a careful consideration. The whole subject, in fact, is one of such close interrelation between the several components as to require close study to secure a firm grip on it.

So it will be well to look into the subject as a whole. The prime source of speed is, of course, power. The development of this has been covered previously, as well as its accurate determination or measurement. When it comes to use, however, another question enters, namely, the matter of efficiency of the transmitting members. This is determined as much by the design and location of the members themselves as by their bearings.

Without going into the former, the latter may be expressed in tabular form. Thus there are several forms the transmission of power between the engine and road wheels may take. The following might be mentioned: Bearings, plain, taper, roller, ball; shaft drive means either bevel or spur gears, of which there are several kinds, while chain driving introduces another variable. Tabulating these and the losses which their use entails, all of the figures being for a single unit of the kind mentioned, the table below is obtained. To care for the figures in the case where more than one of each kind of unit is used, simply multiply by the number used.

POWER LOSSES FROM VARIOUS SOURCES

Source of Power Loss	Amount of Loss Per Cent	Efficiency Per Cent
Plain Bearing	2 1-2	97 1-2
Taper Roller Brg	1-4	99 3-4
Annular Ball	1-8	99 7-8
Universal Joint	4	96
Roller Chain	2	98
Silent Chain Hor	2	98
Silent Chain Vert	4	96
Spur Gears—Steel Greased	9	91
Spur Steel Pinion—Fiber Gear	11	89
Spur Rawhide Pinion—C. I. Gear	12	88
Spur Steel Oil Bath	7	93
Bevels Steel Oil Bath	11	89

This table gives a clear idea of how the power is lost between its generation in the cylinders of the engine and the tire surfaces where it becomes of use. Some idea of this total loss may be gained from the simple statement that the whole efficiency, considering every member and every bearing, is taken as 70 per cent. This is to say, that 30 per cent. is lost through the various small items, given in detail in the above table.

Between the surface of the tires and the road surface, or metal, as the English call it, there is a sort of bond of union, which is called adhesion. This is due in part to the action of gravity pressing the load above down onto the tire so that the latter must adhere fairly close to the road surface, and in part to the natural adhesion of rubber, although smooth to the rough road. Adhesion as a physics term is defined as the molecular connection of bodies in contact. This expresses the exact idea. The car standing on the road, so that the tires are in molecular and intimate contact with it, causes the rubber to adhere to it. The influence of gravity being a constant quantity is at some times a detriment to speed, which is but the instantaneous removal of parts from adherence, only to permit new and instantaneous adherence to take place at an advanced point.

There is, then, a continual breaking of old bonds and a making of new. The rate at which these are broken and remade determines the speed, the making depending mostly upon the weight of the vehicle, while the breaking of them depends solely upon the amount of power supply and the method of its use. This adhesion is a variable, and as yet not exactly determined quantity, but for all ordinary computations it is taken as 148 pounds per ton.

Against speed driving and, in particular, against high speed, the road surface offers a resistance of its own. This is irrespective of other conditions of tractive force, of adhesive effort or any one of the other items which enter into the complex problem. It is another quantity which has not been determined with a positive and certain accuracy, so must be taken as about 50 pounds per ton of actual weight of vehicle. It is an actual resistance, which must be overcome by the power which is at hand, and therefore a subtractive quantity considering the power alone.

To mention another subtractive quantity, the wind. The resistance of the air to the swift passage of any body is very great fully as great as the force of the wind moving at the same speed against the stationary vehicle, action and reaction being equal That this is not a negligible quantity is best expressed by the statement that electric trolley car builders found that straight front cars could not be used for speeds above 60 miles per hour. For very high speed work it was found necessary to so shape the front as to "cut" the air, making its entrance easier. While this does not actually reduce the cross-section, or area of the body.

RELATION OF WEIGHT AND SPEED

$$\text{Energy} = \frac{\text{Weight} \times \text{Velocity}^2}{2 \times \text{Gravity}} = \frac{W \times V^2}{2g} = \frac{W V^2}{64.4}$$

Taking a velocity of one mile per hour

$$\frac{5{,}280 \text{ ft.}}{3{,}600 \text{ sec.}} = 1.466 \text{ ft. per sec.}$$

V equals miles per hour times 1.466,
So, V^2 equals V^2 (m. p. h.) x 1.466,
Substituting:

$$\text{Energy} = \frac{1.466}{64.4} W V^2 \text{ (m. p. h.)} = .02276\ W V^2 \text{ (m. p. h.)}$$

Thus, if a car weighs 4,000 pounds, at 20 miles per hour its energy of motion is: .02276 x 4,000 x 20^2 or, 36.416 foot pounds.

On the other hand, a car weighing but half of this or 2,000 lbs., running at the same speed, has an energy of motion of: .02276 x 2,000 x 20^2 or 18,208 foot pounds, just half the previous case.

The effect of speed is much greater than that of weight. Suppose the speed be twice that of the first case, or 40 m. p. h. Then: the energy is .02276 x 4,000 x 40^2 or 145,664 foot pounds, four times as much as before. The conclusion, then, is that doubling the weight doubles the energy of motion or inertia, while doubling the speed quadruples the energy of motion. Excessive speed, then, possesses twice the menace to life and limb that very high weight does.

RELATION OF WEIGHT TO POWER

Let W equal weight of car, P equal power, E equal the efficiency of transmission, that is back of engine and up to but not including tires on road, V equal the speed in miles per hour, K the coefficient of adhesion of the tires, of the efficiency of contact between tires and road surface.

Then, the maximum power which can be supplied, a further application resulting in slippage, is:

$$P\,(\text{Max}) = \frac{88\ W \times V \times K}{33{,}000 \times E}$$

That is, expressed in words, the power necessary or maximum is equal to the inertia of the moving body times its efficiency of contact with the road surface, reduced from foot pounds to horsepower, and divided by the efficiency between the engine and the tires.

To take a numerical example of this, let the weight of the car be 4,000 pounds as before, the speed 40 miles per hour as before. Now the weight on the driving wheels is never more than six-tenths (.6) of the total weight, so the weight to be substituted in the formula is .6 x 4,000 or 2,400 lbs. The efficiency of the transmission from engine to wheels may be taken as 70 per cent. By experiment it has been found that a fair figure for the efficiency of tire adhesion is 60 per cent., substituting in the formula:

$$P = \frac{88 \times 2{,}400 \times 40 \times .6}{33{,}000 \times .7} = 219.4 \text{ horsepower.}$$

by making its entrance and exit easier, brushing aside the resisting air, so to speak, the speed was found to be greater. Not only was a higher speed permitted, which previously was impossible, but this was done with a lower expenditure of power than before. The back of the car received as much attention as did the front, for it was figured that if the resistance in front was so great there must be a tremendous suction behind. That this was actually the case was shown by the speed which the cigar-shaped electric cars of the German railways attained, 127 miles per hour, with a comparatively modest power plant.

This point was well accented by the experiments of S. F. Edge with a Napier car at Brooklands track in England. In the tests a six-cylinder car of 38.4-horsepower was used, upon the front of which had been erected a framework. This had for a facing removable laths which were added to or reduced in successive experiments. The actual speeds made with the varying sizes of frontal area were as follows:

EFFECT OF FRONTAL AREA ON SPEED

Area of Screen	Time Seconds for Quarter	Speed Miles per Hour
30	18.4	47.85
28	18.0	50.0
26	17.0	52.9
24	16.0	56.2
22	16.6	54.0
20	16.2	55.5
18	15.8	57.0
16	15.6	57.6
14	15.0	60.0
12	14.4	62.5
10	14.0	64.2
8	13.6	66.2
6	12.8	70.3
4	12.0	75.0
2	12.2	73.8
None	11.4	79.0

This table explains more clearly than words the effect of an adverse head wind. If it be considered that the engine developed its maximum, and therefore the same power in every one of these cases, the very large loss in power due to wind resistance may be noted, the difference in the speed between full screen and no screen being no less than 65 per cent. This expressed in terms of the ordinary power plant would mean the difference between a 25-horsepower unit and one of 42 horsepower.

This, of course, was by way of an unusual addition to the usual frontal area, and one that would hardly ever be met with in ordinary work, but it serves to show the very marked influence of a quantity ordinarily neglected. Makers of racing cars should give this point as much attention as is given to the refinement of power plants, because this economizes power. Except for a few sporadic attempts on the other side, and the Baker "Teakettle," this is a carefully neglected point. It is worthy of mention that the latter astonished the world with its performences on the Florida sands some few years ago. The credit was given, however, to the unusual power development of the engine, rather to the non-air-resisting qualities of the peculiar body shape, which economized on the power output.

For all ordinary cases of figuring out power for any given case, the frontal area is taken as 15 square feet, but cases have been known in which this has been reduced to 12 square feet without affecting any other part or function of the car as a whole. This seems like but 3 square feet, but it really is a subtractive quantity of 1/5 or 20 per cent. In the Edge experiments, tabulated above, the first 20 per cent. reduction in frontal area increased the speed or power if you wish it, by 17.4 per cent., while a second reduction of any equal amount increased the speed or power by less than 2 per cent. It is apparent from this, then, that the first reduction is by far the most important, and carries by far the greatest weight.

To propel the car at a high speed, or better, at a very high rate of speed, the necessary tractive adhesion falls off somewhat rapidly, the more so than the speed increases. This may be noted from a careful inspection of the various formulas given elsewhere on this page and the opposite one. At slow speeds, and for starting purposes, high tractive adhesion is a positive necessity. This really is a fortunate circumstance, if it may be called that, being one of Nature's immutable laws, for at high speeds, the tire tread is in poor contact with the road, due to its own and the road's irregularities, which keep it bumping into the air a goodly portion of the time. The need is thus apparent for high tractive adhesion for ordinary uses, for starting, and for running at slow speeds, but at high speed, that is, for racing work, the law allows of "weight paring." More than the fact that the latter is not a necessity, it becomes a duty to take as much of the weight as possible from the tires, for these have come to be the real stumbling block in the way of excessive speed. Not that the tire makers have not done their part—for they have done very well—but the nature of the service is such that no delicate fabric could be expected to withstand it. This is a trying situation, and one which the tire companies are making efforts to cope with in a manner similar to the tire situation.

AIR AND TRACTIVE RESISTANCES

Air resistance enters as follows: Power is reduced by the resistance to traction, to the force of gravity tending to hold the car stationary, and by the resistance of the air. This is expressed in the formula:

$$V\,(\text{Speed}) = \frac{P \times E \times 375}{(T_r + G_r) \times W + A \times R_a}$$

In which, P is the actual power, E the efficiency of transmission, T_r the tractive resistance, G_r the resistance due to gravity, W the total weight, A the frontal area, and R_a the air resistance, which is found by $R_a = V^2\,(\text{m.p.h.}) \times 1.466 \times .0017 = V^2 \times .00249$.

SOLUTION OF RADIATOR TROUBLE

Editor THE AUTOMOBILE:

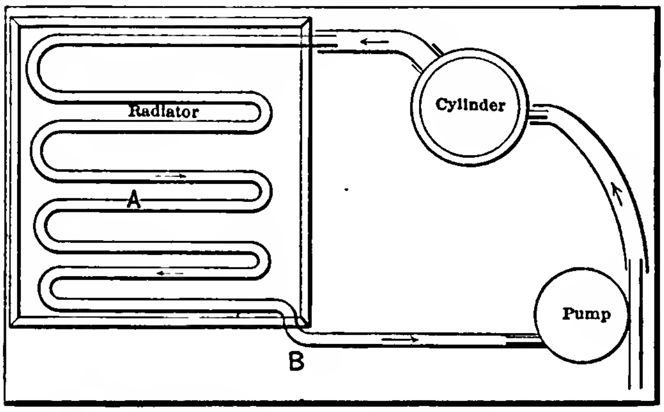
[2,168]—Should the outlet elbow on the bottom of the radiator be as large as the circulating tubes in the radiator? I derive much help from your answers to "Letters" about automobile troubles, and hope that you can help me. I have a Northern two-cylinder, 5 1-4 by 5 1-4 car, with which I have always had considerable trouble from overheating. The water boils and steams more or less all of the time. In putting on new hose connections the other day, I noticed that the brass elbow outlet on the bottom was very much smaller than any of the other pipe connections on the top, either to the pump or to the cylinders. When the radiator was steaming and boiling at the top, I placed my hand on the small outlet and found it to be barely warm. It occurred to me that the water could not flow fast enough through this reduced outlet to circulate the water to the pump as fast as the latter could handle it. The pump does not suck the water to it but merely circulates the water it receives. Would you recommend putting on a larger outlet? I enclose a sketch showing the connections.

Newark, N. J. R. E. HEINISCH.

As the letter is understood, the outlet referred to is marked B in the appended sketch. This would probably be of a smaller size than the inlet at the top of the radiator, where the heated waters enters, on purely technical grounds. The reason for this is—heating the water expands it just the same as it does any metal, and unless the speed of flow is increased, which is not advisable, the same amount of water flowing in the same length of time would need a slightly larger opening at 200 deg. Fahr. than at 70 deg. Fahr. As a matter of fact, radiators to-day are made with equal sized inlet and outlet openings, as a matter of reducing the number of different parts used, and thus, the cost, the same casting being used (where possible) for both inlet and outlet. This opening is, however, proportioned to the water flow at the highest possible temperature and consequently highest possible volume, being at the same time proportioned to the lowest useful speed. It is then too large at lower temperatures and speeds. This is, however, a very good fault, and one from which the radiator is not suffering as evidenced by the steaming and boiling which the writer mentions.

By all means put on a new connection, and make it larger, much larger than the old one, even going to the extreme of making it larger than the inlet. If this does not stop the steaming and general overheating of the cooling system, the radiator capacity is too small for the size and power of the engine. If you do all in your power to get the water into the radiator and out again, that is all that can be done with the given size of radiator. If more capacity is necessary, as shown by continued steaming and overheating, after this is done, the only thing left is to get a new and bigger radiator.

There is this to be said about getting a new radiator: the radiator builders have reached such a high degree of skill in building coolers, that the same sized radiator as they are now built will doubtless suffice to cool your engine. It is, of course, possible that there is something wrong with the water jackets or other internal parts of the engine, which cause it to overheat more than other engines, but by following out the advice given in regular order, you will soon arrive at the proper conclusion.



Sketch of Radiator Layout Which Gave Trouble

LETTERS INTERESTING

IDENTITY OF VARIOUS CARS

Editor THE AUTOMOBILE:

[2,169]—Will you please answer the following questions through "Letters Interesting, Answered and Discussed?" 1. Is the Keystone car made at Yonkers, N. Y., of foreign construction? 2. Is the Simplex car driven by Robertson in the Fairmount Park race an American or a foreign car? 3. What car is acknowledged to be the fastest stock car in the world? 4. What became of the Haynes car that ran in the 1906 Vanderbilt Cup race.

Denison, Kan. LISLE H. SCNEDER.

Many questions are very hard to answer with a direct yes or no, and the above, or some of them, come in this class. Thus, question 3 cannot be answered in this way. No one car has ever so overshadowed all others as to receive by universal consent the title of champion stock car. In fact, it is just this little difference of opinion as to which is the best that continues to furnish material and men for the constantly recurring stock car races. As to question 4, the best way to find this out will be to write to the Haynes Automobile Company, Kokomo, Ind., couching your question in easily understood language, that is, making it clear just what you want to find out.

The other answers are: 1, the Keystone car made at Yonkers is made from American materials, by American mechanics. This company was formerly located at Dubois, Pa., when the car was called the Keystone Six-Sixty. It was fully described in THE AUTOMOBILE for July 15, 1909, page 109. Question 2. The Simplex car which Robertson drove in the Fairmount is made in New York City, and of a very high grade of material. This car uses much of imported steel, and other material, but does not build a special racing car, its racing machines being but stripped stock cars.

CHECKING UP TIMING FROM MARKS

Editor THE AUTOMOBILE:

[2,170]—Please tell me through "Letters" how to check up the timing of my engine. The timing is marked on the flywheel, but I am only a beginner and do not understand it. How much clearance should be allowed between the slider and valve stem?

Hammondsport, N. Y. S. M. B.

The flywheel will be marked with four or five marks, which are labeled as follows: Inlet opens, inlet closes, exhaust opens, exhaust closes, and possibly an additional line, marked firing point, although the latter is doubtful, as the firing point varies so widely.

The marks mean just what they say. When the flywheel is turned so that the line marked "inlet opens" comes up to the pointer, then the inlet valve in the cylinder should just begin to open at that point, being partly opened farther on and entirely closed at a previous point. Similarly with the exhaust. Turn the flywheel over slowly until the line "exhaust opens" comes up to the pointer, then just at that point, no sooner and no later, the exvalve must begin to open. In case yours is a multi-cylinder engine, there will be four times as many marks as indicated above, these being marked with the number of the cylinder to which they apply. Cylinders are always marked from the front end back, the front cylinder being called one, the next two, the next three, and the rear cylinder (on a four) four. Then, when the mark says Number 1 inlet opens, you will know just which cylinder to look to, to see if the marking is correct. The clearance varies by small amounts, but it would be safe to assume it as between 1-32 in. and 1-16 in., but nearer the former.

ANSWERED AND DISCUSSED

FLYWHEEL WEIGHT AND VIBRATIONS

[2,171]—I have a four-cylinder, four-cycle marine engine of 7-inch bore and 6-inch stroke. Valves are 3⅛ inches in diameter and the flywheel size 17 inches. The flywheel weighs 125 pounds. This engine is in a speed boat, in which it runs up to 1,000 revolutions per minute. When running at 200 to 500 revolutions there is practically no vibration and the engine runs finely. At 600 to 700 revolutions the vibration is very bad, but at 900 to 1,000 revolutions it disappears again. I have tried all kinds of mixtures with three different carbureters. The pistons of this engine weigh 20 pounds apiece and have four rings, all placed at the top. About how much power would I gain if I took off two of the top rings and bored the piston out on the inside so as to make it lighter by three pounds per piston? What is the need of four rings on a piston, anyhow, as I read of some racing cars with but one piston ring?

Haverhill, Mass. J. G. HUDSON.

Balance, which is reflected in steady running and the absence of vibration, is brought about by a flywheel which is in correct static and running balance, as well as moving parts (crankshaft, connecting rods, pistons and piston pins). If these are out of balance the engine will run streaked as you say yours does. A good scheme would be to use a larger, heavier flywheel, as increased flywheel weight and diameter, which usually spells weight, increase the steadiness of running of any engine. In fact, with a large enough flywheel, the small vibrations due to a lack of balance of the reciprocating parts are completely offset.

Reducing the weight of the pistons will help, although it may alter the compression and seriously. The function of piston rings is to make a sliding connection which is gas tight against high pressures. If the makers judged four rings to be about right for this purpose, reducing the number to two would double the chances of the compression pressure escaping. As to racing machines using but one ring, the writer has heard of but one, and that machine used what was one ring in name only, being actually double arrangement so that the result was that usually obtained by two or more rings, this unique construction being resorted to in order to save weight down to the very last ounce. The change in the pistons, that is, boring them out, will be a very good one, but every one must weigh exactly the same.

LEMOINE TYPE AXLE DESCRIBED

[2,172]—I have frequently heard of and read of the Lemoine axles, but have never seen or heard anything to give me a clue as to just what was meant. Will you tell me through the columns of "Letters" the name of this firm, where it is located, what the firm makes, and also what the special type of axle is, which has been given the firm's name?

Far Rockaway, N. Y. G. A. ERNEST.

A section through an axle known as the Lemoine is shown. This firm is a famous French one, which has turned from fine work in machinery to automobile products, and now makes and sells springs, axles, transmissions, steering gears, and many other parts, all of the highest quality. The full name and address is just plain Lemoine, 21 Rue de Lappe, Paris.

The front axle to which this name has been given is so made that the axle bed or central part is placed on the axle spindle so as to rest upon it, with thrust washers interposed. Other front axles are placed either yoked around the spindle so as to touch it both above and below, or the reverse of this, with the spindle end yoked around the axle end, so as to touch it both above and below. Actually, the difference is one of shape.

ONE CYLINDER FIRES PREMATURELY

Editor THE AUTOMOBILE:

[2,173]—As I have not seen anything in "Letters" which gives any information on my particular trouble, I ask you to answer this. I have a four-cylinder Autocar, with everything in good condition excepting only number three cylinder, which fires prematurely. It always does this after getting warmed up, say, after running a mile. When stopping and cutting off the current the engine will continue to run, and the water will stay boiling hot for several minutes. I took off this cylinder and found a spot, a depression, or rather concave part of the piston about 2 inch by 1-2 inch beginning about 1 inch above the lower ring and running toward the bottom or third ring. It was black and rough, caused by burnt lubricating oil. The cylinder walls show nothing but a perfectly smooth wall, with bright regular surface and ample evidence of plenty of oil, also the other cylinders are in prime condition. Remember the four rings of number three piston are all right, showing that every portion of the rings has worked up against the walls. Kindly let me know what is the matter and how to remedy it, as I am at a loss what to do.

Darlington, Md. H. KENTON WHITEFORD.

Since missing is usually if not always due to some flaw in the ignition system, and nothing is said about this important part of the power plant, it is rather hard to give a definite and useful answer to the above case of trouble.

Generally speaking, missing may be caused by a weak spark, which is caused by a wet or damp coil. To remedy this dry out the coil before a slow fire. Missing is also caused by batteries being exhausted. Remedy, test batteries with a voltmeter, and finding this to be correct, substitute new batteries. This kind of trouble usually manifests itself by the engine misfiring after running some time. The cause of it is, the weak cells gather some strength when standing, so fire the engine all right at starting, but after running a short distance, say a mile, the weakened condition of the cells shows itself in the continued missing.

It may be that the spot you mention has something to do with the trouble, but it is hard to see the connection, as it is not exposed either to the fresh gases, to the spark, or to the burned gases at any time in the stroke.

CYLINDER TEMPERATURES AND RECORD

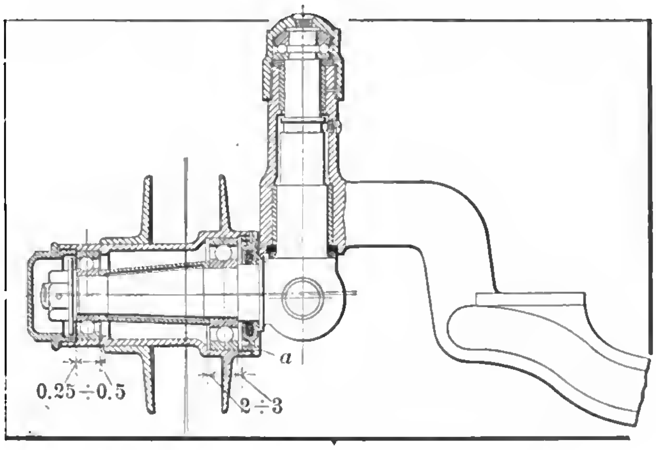
Editor THE AUTOMOBILE:

[2,174]—Please advise me through "Letters Interesting, Answered and Discussed," at what temperature of the cylinder walls, the gasoline engine will be most efficient. I read part of a discussion about this in "The Automobile" at one time, but understand that the figures have been revised since then. Also, will you tell me what make of car holds the time record from coast to coast, or from New York to San Francisco?

Silver Springs, N. Y. HORACE B. BLACKMAN.

The exact temperature to which you refer is just as much in doubt as it was some years ago. Supporters of one kind of engine say at 200 deg. Fahr., while those who favor another type of engine are equally steadfast for a temperature of 350 deg.

Franklin holds the coast to coast record, made however, from the West to the East, or in the reverse direction.



Section Through Lemoine Type of Front Axle.

MERITORIOUS IDEAS FROM ABROAD

Starting a Long-Unused Motor—M. Feron, in *Omnia*, offers a good suggestion as to the best method of starting a motor that has long been unused. He advises the injection of lubricating oil, or of a mixture half oil and half kerosene. Says M. Feron:

"The root of the trouble is in the fact that during the long period of idleness all the oil has run down from the cylinder walls into the crankcase. The pistons are consequently dry, and the metal surfaces are in direct contact with each other, so that they will not hold any gas pressure.

"If a small quantity of thinned lubricating oil is injected, it will flow between and around the piston rings and form a good gas seal; it will disperse the old, dried oil or liquefy it and so render it useful; the motor will answer sweetly to the starting crank, a good suction will be exerted on the carbureter, and the motor will start merrily."

Gnome Inlet Valve—Although the seven-cylinder rotating Gnome motor, which has met with such success in aeronautic work, has been very generally illustrated and described, there is one feature of it which has not received much attention. This is the inlet valve, which is placed in the center of the piston head.

In operation, this inlet valve is automatic. The gas enters the crankcase through the hollow stationary crankshaft. Each valve is balanced against the centrifugal force set up by the rotation of the motor by two small counterweights. The valve spring is a single flat blade, set between these counterweights in such a manner that it is bent whenever the valve opens. Especially neat designing is revealed by the method of setting the valve seat into the piston head, in connection with the bosses for the piston pin.

The piston rings are also unusual. There are in reality two of these, though they look like one. The inner one is of cast iron and the outer, shaped like the letter "L" in cross-section, is of sheet brass. The shape of the ring is such that pressure of gas above it only forces it into closer contact with the cylinder wall.

Cast-Steel Omnibus Wheels—Of a startlingly light appearance, considering the use to which they are to be put, but nevertheless abundantly strong, are the wheels provided by the Atlas Resilient Road Wheels, Ltd., for the London General Omnibus Company. On account of the London police regulations governing the weight of omnibuses, one of the chief considerations in designing these wheels was to make them as light as possible.

The material used is cast steel, and felloe, spokes and hub are all cast in one piece. There are but eight spokes, of an X-shaped cross-section, to each wheel. The average thickness of the steel is about a quarter of an inch. The rims, which are a part of the wheel casting, are adapted to take single solid tires in front and double solid tires in rear. The weight of a front wheel without tire is 88 pounds, and of a rear wheel 203 pounds. The maximum weight allowed to the omnibuses on which these wheels are used is three and one-half "long" tons.

Wimperis Accelerometer—In *Automotor Journal*, January 22, is described and illustrated an instrument recently placed on the English market which indicates the rate at which the car to which it is applied accelerates or slows down. In appearance the device resembles a speedometer, but does not need to be connected to the wheels.

When the car is started the needle swings backward over a part of the scale marked "acceleration," and the figure to which it points gives the rate of acceleration in feet per second per second. Suppose, for example, the needle points to the figure "5"; at that instant the car is then increasing its speed at the rate of 5 feet per second during each successive second of time. If the speed at that moment happened to be 10 feet per second, at the end of a second it would have increased to 15 feet per second.
